In the work described here, the effects of allowing a single disk dynamo to precess are investigated. This model does not exhibit field reversal but does possess an instability similar to that which immediately precedes field reversal in the coupled disk dynamo model. The precessing disk dynamo is shown in Fig. 1. The coil of wire remains fixed while the axis of the disk precesses about the normal to the plane of the coil. The ends of the coil brush against the axle and rim of the disk, utilizing the potential difference induced between these parts by the rotation of the disk in a small initial magnetic field H perpendicular to the plane of the coil. The resulting current I in the coil produces a field which tends to increase H. Given an initial field the system is therefore self-exciting, the energy being provided by a constant couple G applied to the axle of the disk.

The equations describing the model are[12]

$$L\dot{I} = \omega I M \cos\theta - RI$$

$$C\dot{\omega} = G - I^2 M \cos\theta - k\omega$$

$$A\ (\ddot{\theta} - \dot{\phi}^2 \sin\theta \cos\theta) + C\omega\dot{\phi} \sin\theta = mgl \sin\theta$$

$$A\ (\ddot{\phi} \sin\theta + 2\dot{\theta}\ \dot{\phi} \cos\theta) - C\omega\dot{\theta} = 0$$

where the equations of motion have been written using axes that precess with the body; ϕ measures the angular precession and θ the angle between axle and normal to the plane of the coil. The axle is pivoted about a point distance l below the centre of mass of the axle and disk and (A, A, C) are the moments of inertia of the body (of mass m) about the precessional axes. A viscous force $k\omega$ opposes the rotation of the disk. The current circuit has resistance R and self-inductance L, and the mutual inductance between the coil and the rim of the disk is approximated by $2\pi M \cos\theta$ (M remains constant).

The equations may be written in non-dimensional form by introducing four dimensionless parameters. The quantity most difficult to estimate is the ratio L/M. Values assigned to L/M in previous work vary between 1 (Rikitake[11]) and 100 (Allan[9]). In this range of L/M numerical integration of the equations shows that the periods τ_c of current oscillations are longer than corresponding ones in the ordinary disk dynamo by a factor of five at most.

The interesting feature of the model is, however, that τ_c is between 0·3 and 3·0 times the precessional period (τ_p) corresponding to values of L/M between 1 and 100. If one uses the value of τ_p for the Earth ($2{\cdot}6 \times 10^4$ yr) as a measure of τ_c, one obtains values of between $7{\cdot}8 \times 10^3$ yr and $7{\cdot}8 \times 10^4$ yr. From the small amount of data on recent oscillations of the dipole moment it seems that τ_c is about 10^4 yr. Thus if the appropriate value of L/M for the Earth's core is about 10, the ratio τ_c/τ_p for the model is in reasonable agreement with the available data. A first-order stability analysis[12] favours the lower values of L/M because the equilibrium value of the (dimensionless) angular velocity goes as $(L/M)^{-1/2}$. Thus the larger L/M is, the slower the disk spins. Instability therefore becomes more likely as the value of L/M is increased.

The suggestion regarding this instability is supported by the numerical integrations[12]. Even with $L/M = 1$ an initial disturbance in the angular velocity amounting to 10 per cent of its equilibrium value is enough to cause an appreciable increase in the current after three oscillations. Although the current cannot reverse in this model, it is worth noting that in the two-disk model a true reversal (as defined by Allan[9]) is always preceded by an increase in the amplitude of the current oscillations. If the increase in current after three oscillations obtained for the case $L/M = 1$ is enough to cause reversal, an initial polarity interval of about 23,000 yr would be implied.

I acknowledge helpful discussions with Dr D. W. Allan and Dr R. Hide. This work was completed during tenure of an NAS postdoctoral resident research associateship.

Deposition of Manganese Rich Sediments during Glacial Periods

SEVERAL elements, such as manganese, vary considerably in concentration in different sediments. Factors such as chemical weathering, run off from the continents and physicochemical conditions in the transport medium or in the region of deposition may cause these variations, and volcanic and biological processes may also produce manganese-enriched deposits. The effect of such processes on the areal distribution of manganese has been extensively studied, but their effect on the temporal distribution of manganese is little known. Wangersky and Hutchinson[1] found that Caribbean sediments from the last four glaciations are rich in manganese. My data indicate that manganese, copper and calcium carbonate are enriched in sediments from most glacial periods in the Caribbean.

For this study, the Caribbean core *P*6304–9 (14° 57′ N and 68° 55′ W at a depth of 4,126 m) was chosen because eight glacial events are recorded in it[3]. The core was sampled every 20 cm and analysed for $CaCO_3$, NaCl, Mn, Fe, Cu, Y, La, Co and so on. Emiliani determined $^{18}O/^{16}O$ ratios[2] and carbonate concentration (unpublished). $CaCO_3$ was analysed in both cases by the acetic acid leaching technique[3]; the agreement between the two sets of analyses is good. Mn and Fe were determined by both atomic adsorption and emission spectroscopy, and Cu, Y, La and Co by emission spectroscopy. The analytical precision is 2–3 per cent for $CaCO_3$; 10 per cent for Cu, Mn, Co and Fe; and about 20 per cent for Y and La. Most analytical results are shown in Fig. 1, together with the isotope data from Emiliani[2]. Because of scarcity of the material, $^{18}O/^{16}O$ ratios, $CaCO_3$ content and other data had to be determined from different samples. Moving averages involving three consecutive values each time were used to eliminate short term noise in the data without destroying the cyclic patterns (see Fig. 1), because each cycle involves seven to fifteen data points. The trend in the $CaCO_3$ data was eliminated by means of the correction factor $y = +0{\cdot}0074\,x$ (y = content of $CaCO_3$ (in per cent), x = depth in the core (in cm)) which was derived from the trend equation for $CaCO_3$, $y = 57{\cdot}8 - 0{\cdot}0074\,x$. Correlation coefficients were calculated, using the data processed in this way (Table 1).

The curves for $\delta^{18}O$/PDB–1 ($\delta^{18}O$ parts per thousand, with respect to the Chicago Carbonate Standard), Mn, Cu and $CaCO_3$ show cyclic patterns that cofluctuate, particularly in the deeper sections of the core. All data for Mn, Fe, Cu, La, Y and Co discussed here refer to carbonate free basis. The correlation between manganese and $\delta^{18}O$/PDB–1 maxima at 400, 820, 975 and 1,300 cm (see Table 1) is most striking. Less pronounced correlations with $\delta^{18}O$/PDB–1 are shown by maxima in the $CaCO_3$ and

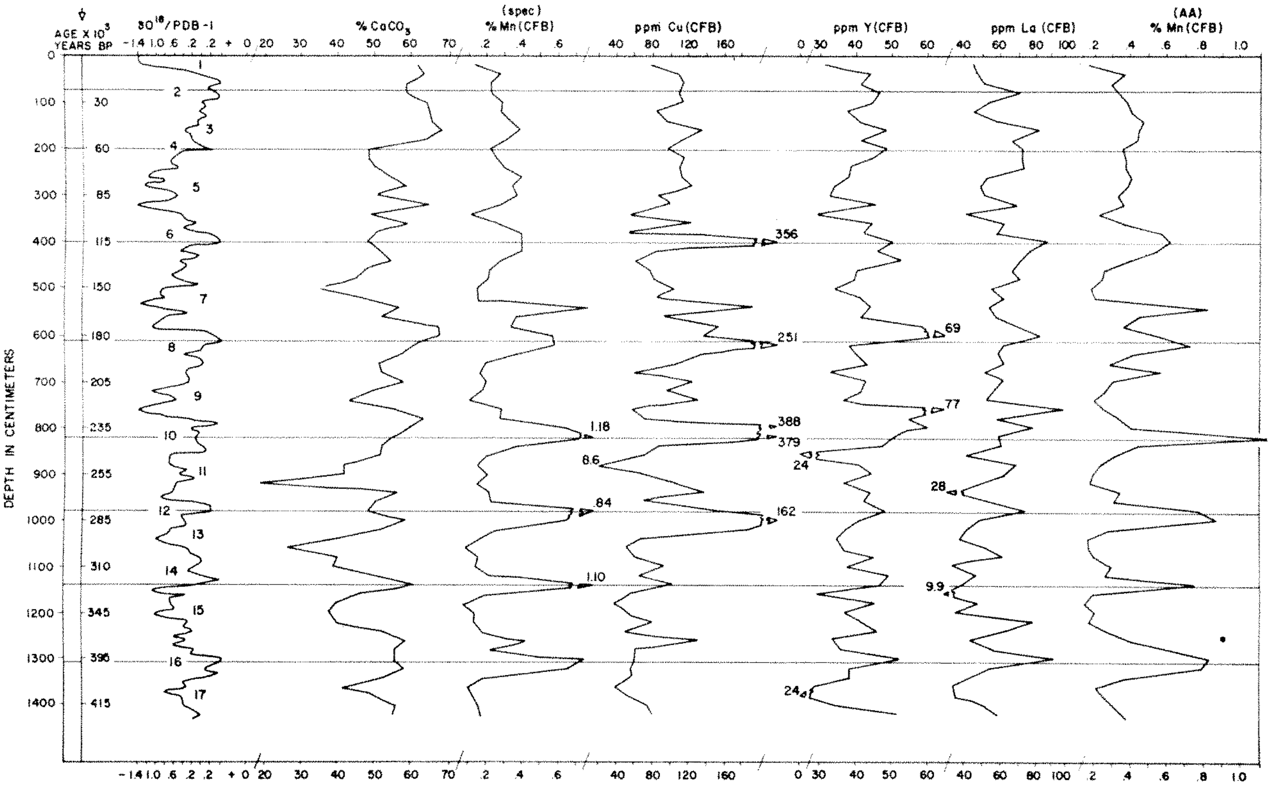

Fig. 1. Analytical results for core *P*6304–9; $\delta^{18}O$ and $CaCO_3$ from Emiliani[2]. Mn (per cent), Cu, Y and La (p.p.m.) are given on a carbonate free basis (CFB). Mn was determined by spectroscopic analysis (spec) and atomic absorption measurements (AA), showing a very good agreement. Two other series of manganese analyses and another series of copper analyses are not shown in the figure but duplicate the data in the Mn (spec) and Cu (spec) curves.

* Close to but above the 5 per cent significance level. † Significant on the 5 per cent level. ‡ Significant on the 1 per cent level.

Column 1 gives correlations for the layer 40–320 cm, 2 for 340–500 cm, 3 for 520–740 cm, 4 for 760–900 cm, 5 for 920–1,040 cm, 6 for 1,060–1,200 cm, 7 for 1,220–1,400 cm, 8 for 340–1,400 cm, 9 for 340–1,200 cm and 10 for 40–1,400 cm. Figures within parentheses at tops of the columns indicate number of samples. Y shows the same correlations as La, probably because of the similarity in distribution patterns for Y and La.

Cu (Table 1). The correlation coefficient between $\delta^{18}O$/PDB–1 and Cu in column 9, Table 1, does not quite reach the 5 per cent significance level, possibly because no long-trend correction was made for Cu, but other calculations indicate that Cu is better correlated with $\delta^{18}O$ than is $CaCO_3$. Thus the absolute discrepancy in peak positions for Mn etc with respect to the $\delta^{18}O$ peaks can be expressed as a fraction $|\Delta\lambda|$ of the length λ of the cycle in which the $\delta^{18}O$ peak under consideration is located. (The error in the definition of λ for each cycle affects all peak discrepancies equally and is of little consequence.) The standard deviation of these peak discrepancies is 0·06 (for Mn–$\delta^{18}O$), 0·12 (for Cu–$\delta^{18}O$) and 0·18 (for $CaCO_3$–$\delta^{18}O$). For Y, La and Co the correlation with $\delta^{18}O$/PDB–1 is poor and Fe showed no correlation.

The oxygen isotope ratio has been used as a palaeothermometer[2], the positive peaks in the $\delta^{18}O$/PDB–1 curve corresponding to cold periods. These data and earlier reports[1,4] suggest that variations in the content of $CaCO_3$ (total sample) and Mn and Cu (carbonate free fraction) are partly climatically controlled. The Mn and Cu content seem to be better climate indicators than the $CaCO_3$ content.

The negative correlation in layer 40–320 cm for ($\delta^{18}O$/PDB–1)–Mn may be caused by some changes in deposition conditions or post-depositional migration or disturbance during sampling, because in core *A*172–6 the events 1, 3 and 5 (ref. 2) are better resolved than in *P*6304–9. Turekian reached similar conclusions for the Equatorial Atlantic Core 180–74 (ref. 5). In the layer 340–1,400 cm the correlation coefficient 0·51 compares favourably with previous results[1].

The correlations between $CaCO_3$–Mn and $CaCO_3$–Cu may not suggest any geochemical affinity between these constituents, but they may be caused by the same controlling climatic factors. The high correlations between the elements Mn–Cu, Mn–Co and Cu–Co are in agreement with what is known about their geochemistry[6].

The formation of manganese rich sediments during glacial periods could possibly be the result of an increase in chemical weathering during these periods caused by pluvial conditions which occurred at lower latitudes simultaneously with the glaciations at higher latitudes[7]. The increase in run off during the glaciations[5,7] could have coincided with an even more accelerated weathering rate. The connexion between pluvial and glacial events does not seem to be fully understood, however[7–10]. Another explanation could be that during interglacial periods, laterites and related weathering products are formed and are brought into the sea by increased run off from the continents during glacial periods. A third explanation could be a more complete removal of manganese from seawater during cold periods. Ocean water contains about 0·002 mg Mn/l. During a cold period of 20,000 years a water column of 3,800 m will deposit at the most 0·012 g Mn/cm², because the residence time of manganese is about 1,300 years[11]. The amount of manganese deposited during such a period is about 0·12 g Mn/cm², however, assuming that dry uncompressed sediment *in situ* contains 60 per cent $CaCO_3$ and has a density of about 0·75. Present weathering conditions are consequently unable to support the deposition rates during the pluvials unless manganese was preferentially deposited in this area.

I thank Dr O. Joensuu, Mr W. Eyl, Mrs S. Valdes and Mr B. Weber for help with chemical analyses and correlation calculations. This work was supported by grants from the NSF and the American Chemical Society.

Finite Elements for Geological Modelling

SCALE models have often been used to illustrate or gain insight into geological processes[1,2]. It may now be possible to study full scale models using a digital computer and the finite element method—a method of stress analysis in complex structures developed in the engineering sciences[3].

Fig. 1 represents a cross-section through part of the Earth's crust: the thickening of the crust at *A* and *B* is intended to represent mountain chains with compensating roots on the Airy principle of isostasy[1]. The length of the cross-section is 800 km and the minimum thickness of the crust is 25 km (vertical exaggeration 4 : 1). With this simple model the finite element method could be used, say, to investigate the effects of deposition in the broad trough between the two mountain ranges, accompanied if required by erosion of the mountain ranges. The effects of tectonic forces could also be included. Here I simply illustrate the method by considering deposition in the trough.

The finite element method requires that a continuous structure be replaced by a series of elements (the tri-

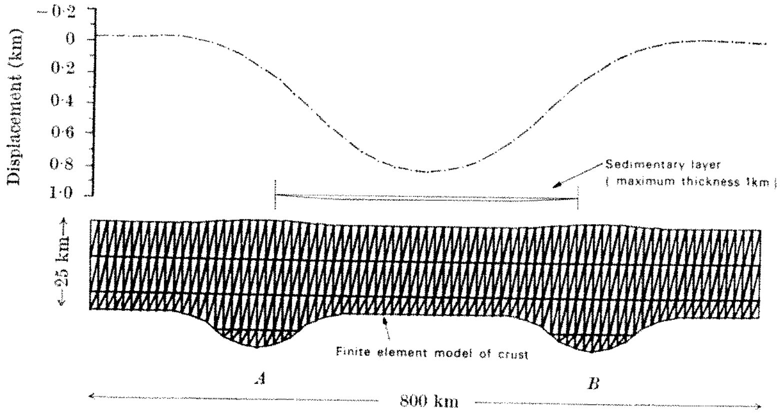

Fig. 1. Cross-section through a finite element model of the Earth's crust with computed displacement from loading with a lens of sediment.

angles of Fig. 1) which are assumed to interact at only a few points called nodes (the vertices of the triangles). Then, whereas the displacements in a continuum must be specified at an infinite number of points, displacements in the finite element method are specified in terms of the displacements of the nodes. For each element a stress–nodal displacement relationship is formulated in terms of the elastic constants and dimensions of the elements, and these relationships are assembled into a larger set of equations which describe the deformation of the whole structure under load. These equations have the form:

$$[\mathbf{F}] = [\mathbf{K}]\ [\mathbf{Y}]$$

where [**F**] is the load vector (including body forces), [**Y**] the displacement vector and [**K**] the stiffness matrix. To include the effects of buoyancy (the crust is supported by a viscous substratum on the classic theory of isostasy[1]) the vertical component of the load vector acting at the base of the crust is made to vary linearly with the vertical displacement.

To simplify the computation, the cross-section of the model (Fig. 1) is constant at right angles to the cross-section. Simple triangular elements can then be used, the displacements of the nodes being confined to the plane of the cross-section. This is the condition of plane strain.

Using a program given by Zienkiewicz[3] I have computed the displacements of the model (Fig. 1) resulting from the deposition of a lens of sediment (density 2·6 g/cm^3) 1 km thick at the centre of the trough and thinning towards the flanking ridges. (The load of sediment is actually replaced by equivalent vertical point forces acting at the appropriate nodes.) The program was modified to include the effects of buoyancy, the density of the crust was taken as 2·8 g/cm^3 and the density of the substratum as 3·3 g/cm^3. A Young's modulus of 10^{12} dynes/cm^2 and a Poisson ratio of 0·25 were taken for the elastic constants of the crust. The crust has been assumed to be uniform, but this is not essential, and each element could have different elastic properties: in this way geological structures can be simulated. Elements with zero strength can be used to simulate faults (Zienkiewicz[3]).

Fig. 1 shows the lens of sediment and the computed deformation of the crust resulting from the loading. As would be expected, the greatest deformation is at the centre of the model. Small uplifts of the crust on the flanks of the downwarp also occur. Similar effects have been found by Vening-Meinesz[4] in his classical studies of the deformation of a uniform rigid crust under loading. The maximum depression of the crust in the model is 0·81 km, about what one would expect: a uniform crust floating in a viscous substratum of density 3·3 g/cm^3 would subside by 0·79 km under loading with a uniform layer of sediment 1 km thick and density 2·6 g/cm^3. The crust as a whole proves to be in equilibrium under the sedimentary load because $\rho_s A_s = \rho_v A_v$ as it should (ρ_s is the density of the sediment, A_s the cross-sectional area of the sedimentary layer, ρ_v the density of the substratum and A_v the integral of the displacement of the base of the crust over the whole cross-section).

The model described here is crude, but its behaviour under load suggests that, with refinement, it could be used to study the build-up of stresses within the crust as a result of the relatively simple processes of erosion and deposition. This may show that, for example, some rift valleys are explicable as the results of differential loading of the crust. The effects of deposition along the continental margin could also be modelled. If these studies give useful results increasingly more complex models can be investigated: the effects of elastic anisotropy, heat flow, fluid flow through pores and nonlinear deformation are already being included by civil engineers in finite element models[3]. By incorporating more and more of the accumulated mass of geological, geophysical and geomorphological data, very elaborate models can probably be constructed with which to test tectonic hypotheses. This should help to show which of the many hypotheses are consistent both within themselves and with the observational data.

Continental Climatic Variations between 130,000 and 90,000 Years BP

CLIMATIC variations in the Quaternary have so far been described with some precision, in the range of 0 to 35,000 yr BP, by radiocarbon dating and by using the isotopic ratio $^{18}O/^{16}O$ to estimate temperature. The ratio was measured either in foraminifera[1] for the marine environment, or in stalagmites[2-4] for the continental environment.

Corals, which may be dated back to about 500,000 yr BP by the uranium desequilibrium method, may be used to determine dates outside the range of ^{14}C measurements. These corals also reflect sea level variations associated with temperature. Variations of foraminiferal associations[5] or their isotopic composition[6] can also be used, but radiometric methods are not very accurate in these cases. More often, mean sedimentation rates have been assumed. From these data, correlations with the Milankovitch summer insolation curve, a cyclic variation of 21,000 yr related to the precession and a period of 41,000 yr due to the tilt of the Earth's axis[7], have been attempted[8].

Accurate data are therefore necessary both for dating and for temperature evaluation for periods outside the range of ^{14}C dating, and especially for the periods of transition between warm and cold periods.

We have previously shown that, in certain conditions, $^{18}O/^{16}O$ ratios in stalagmites give a good indication of the mean temperature of the air above the cave[9] and that old stalagmites may be dated by the $^{230}Th/^{234}U$ method[10].

In the Aven d'Orgnac (43° 50′ N, 4° 30′ E) in southern France, we found a stalagmite which was formed between

130,000 and 90,000 yr BP, during the interglacial Riss/Wurm. This stalagmite is 244 cm high, very pure, and has regular cylindrical shape about 10 cm in diameter. It was growing about 3 km from the entrance of the cave, and, consequently, out of the influence of the outer atmosphere. Samples for dating were taken from the central part of the column to avoid contamination by clay or by secondary crystallization in the outer edges. Isotopic analyses were performed on 30 mg samples taken from the axial part of the stalagmite, because, in this part, the isotopic composition of the calcite was highly reproducible[9]. Each sample was treated, at 25° C in vacuum, by 100 per cent H_3PO_4, and the CO_2 obtained was then purified and analysed with an Atlas *M* 86 mass spectrometer.

Table 1 gives the results of uranium dating and of $^{18}O/^{16}O$ measurements, and Fig. 1 gives the curve of variations of $\delta^{18}O$ with time.

We have previously shown[9] that the oxygen composition in a cave is related to temperature variations only if there is no air movement and no relationship between carbon fractionation and oxygen fractionation. Fig. 2 shows that there is no correlation ($r = 0{\cdot}33$) and in this case the variations of $^{18}O/^{16}O$ do represent temperature variations.

* Using the relationship

$$\left[\frac{^{230}\mathrm{Th}}{^{234}\mathrm{U}}\right]_{\text{measured}} = \frac{(1 - e^{-\lambda_{230_{\mathrm{Th}}}t})}{(^{234}\mathrm{U}/^{238}\mathrm{U})_{\text{meas.}}} + \left[1 - \frac{1}{(^{234}\mathrm{U}/^{238}\mathrm{U})_{\text{meas.}}}\right]$$

$$\left[\frac{\lambda_{230_{\mathrm{Th}}}}{\lambda_{230_{\mathrm{Th}}} - \lambda_{234_{\mathrm{U}}}}\right]\left[1 - e^{-(\lambda_{230_{\mathrm{Th}}} - \lambda_{234_{\mathrm{U}}})t}\right]$$

$$T_{230_{\mathrm{Th}}} = 75{,}200 \text{ yr}$$

$$T_{234_{\mathrm{U}}} = 2{\cdot}48 \times 10^5 \text{ yr}$$

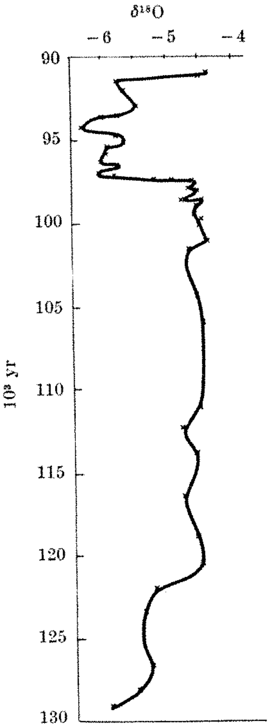

Fig. 1. Variations of $\delta^{18}O$ versus ages in the Orgnac stalagmite.

Dansgaard[11,12] has shown that Greenland ice has low ^{18}O concentrations when it corresponds to a cold period. Assuming that this phenomenon is general for rain waters in high and middle latitudes, the Dansgaard relationship gives an enrichment of 0·69 ‰ in ^{18}O for an increase of the temperature of 1° C. These results will be more precise when the isotopic and thermal variations of oceanic waters are better known, because the isotopic composition of rain water depends on these factors.

The fractionation of oxygen at the moment of crystallization of calcite is also an important factor. McCrea[13] has shown that in equilibrium conditions, an increase of 1° C in the temperature of the environment produces a 0·24 ‰ decrease in the fractionation factor in the calcite.

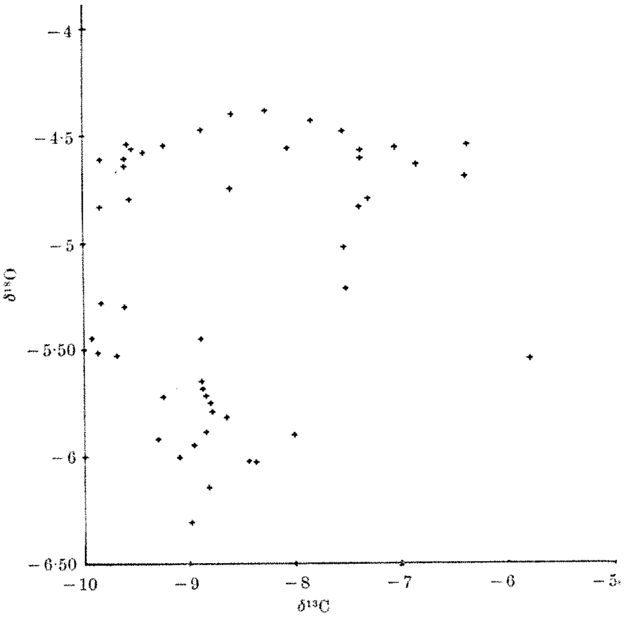

Fig. 2. Correlations between $\delta^{18}O$ and $\delta^{13}C$ in the Orgnac stalagmite.

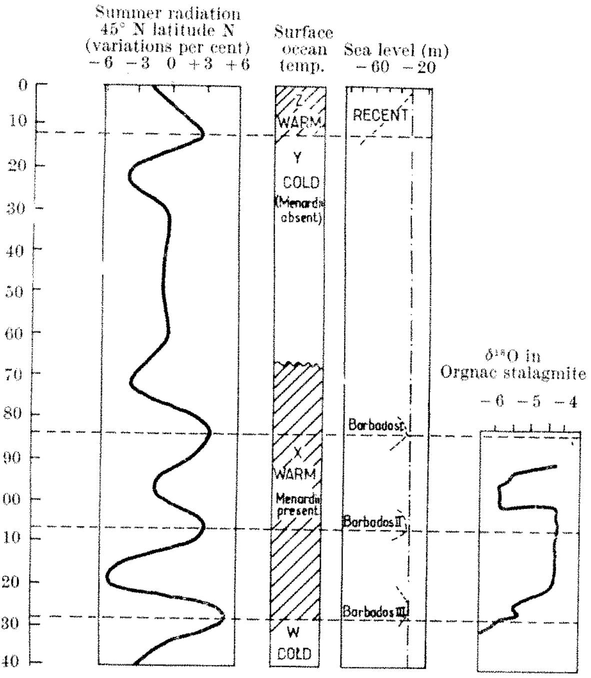

Fig. 3. Correlations between the variations of intensity of solar radiations, surface temperature of the oceans, the sea levels (from Broecker[8]) and the variations of $\delta^{18}O$ of the Orgnac stalagmite.

If the temperature above the cave varies by Δt, these hypotheses give the following relationship

$$\Delta^{18}O = 0{\cdot}69\,\Delta t - 0{\cdot}24\,\Delta t$$

That is

$$\Delta^{18}O = +0{\cdot}45\,\Delta t$$

On our curve, the maximum variation in temperature is 4° C. The temperature increased slowly (4° C in 10,000 yr) from 130,000 to 120,000 yr BP. It then remained approximately constant, with only minor variations ($<0{\cdot}5$° C) from 120,000 to 97,000 yr BP. This relatively warm period ended abruptly 97,000 yr ago when, in about 1,000 yr, the temperature fell about 2·5° and was followed by variations, the minimum being about 95,000 yr ago. Between 93 and 92,000 yr BP, that is in 10^3 yr, the temperature rose by about 4° C.

The first conclusion that may be drawn from this curve is that the time constants of climatic phenomenon may be very short. There is also no correlation between the Milankovitch curve and our curve, and it is evident that there is no 21,000 yr periodicity. Unfortunately, our record is too short to study the possibility of a 40,000 yr periodicity. This result agrees with the conclusion of Shaw and Donn[14] that the Milankovitch effect is too small to have induced glaciations.

If, according to Broecker's hypothesis, we assume that the Ericson X zone represents Wurm Riss interglacial, our curve shows the start of rewarming and covers a great part of the warm period. It is possible that the short cold episode, about 95,000 yr ago, was too short to have influenced the foraminiferal fauna of the Caribbean sea.

The high sea level represented by Barbados III may be correlated with the rapid increase of temperature between 125 and 120,000 yr BP, but it is not so easy to explain another high sea level corresponding to Barbados II. Minor variations of the sea level may have occurred, and this would explain, as Barbados II is lower than Barbados III, that Thurber *et al.*[15] and C. L. *et al.*[16] have found in atoll drills only one high sea level about 100,000 yr ago, which corresponds to the end of a warm period. Rona and Emiliani[17] have also found that a cold period occurred about 100,000 yr ago.

We thank the Municipality of Orgnac for allowing us to work in the cave and to sample stalagmites. We also thank M. Guy Rieu for his help and Mrs Paulette Martineau for helping us to prepare the samples.

Variation in Weather-type Temperature Averages

Barry and Perry[1] describe an analysis which asserts that the mean temperatures of weather-types exhibit a "within-type" change between 1925–35 and 1957–67 at Eskdalemuir (55° 19′ N, 03° 12′ W, 242 m) for January, April, July and October. The authors concluded that Dzerdeevskii's hypothesis[2]—that all changes in temperature and precipitation are associated with changes in frequency and duration of large-scale circulation patterns—needs to be modified at least on the local scale in Britain. Some of the procedures used are, however, open to criticism and their conclusion may therefore be invalid.

Possible sources of error or difficulties in assessing the results might arise from changes of site, surroundings, observational procedure and instruments at Eskdalemuir Observatory.

Details of the site[3] and the history of its developing shelterbelts, up till 1958, are given elsewhere[4]. In the 1960s, the mature trees had become vulnerable to strong winds and, according to a forestry report of September 1967, even the more deeply planted shelterbelt on the east side and nearest to the thermometer site was substantially impaired. The comments by Callendar[5] on Eskdalemuir shelter and extensive research on windbreaks[6,7] suggest that the changes at Eskdalemuir are sufficient to merit serious consideration in any temperature-trend studies.

Investigations[8] in 1957 showed that winds from the Glasgow and Newcastle areas could be identified as pollution carriers. Although surface concentrations of air pollution at Eskdalemuir are small, possible effects on temperature of the complex neighbouring urban meteorological regimes cannot be ruled out.

Between 1925 and 1935, the temperatures used are presumably the daily maxima and minima for periods terminating at midnight[9,10], while for the period 1957–67 it is understood that the maxima refer to the "day-time" period from 0900 to 2100 and the minima to the "night" period from 2100 to 0900. This change of procedure might account, at least partly, for the decreases of maxima in January and July and the increases of minima in April and October, in Table 2. Presumably, the two algebraic expressions used for Table 2 should read

$$\Delta F_A(T_A - T_1)/N \text{ and } \Delta T_A, F_{2(A)}/N$$

Up to the end of 1956, all available maximum and minimum temperatures were measured in a large louvred (photothermograph) hut[10], but from 1957 the published and computer-processed temperature extremes were obtained from a large louvred screen using standard thermometers.

Analysis difficulties arising from such changes may often be overcome by the study of "station histories", the use of long consecutive series of data[11] rather than relatively short and isolated periods and by comparison with other suitable stations.

Confirmation of the results might be obtained from stations in the same area, but both the weather-type–temperature relationship and its trends may well differ from region to region. For example, in Scotland the coldest surface wind directions in winter are north-westerly or northerly, whereas in south-east England the lowest mean temperatures occur with easterlies or north-easterlies. A change to higher sea temperatures may cause a significant increase of mean air temperature in Scotland with south-easterlies, while a similar but much smaller effect in south-east England might be masked by other factors, or the total change there might be made even negative.

It is questionable whether the "Lamb catalogue" (details of which are not stated and are not as yet generally available) of daily synoptic weather classification of the United Kingdom area is suitable for an investigation concerning a particular station. The range of wind variation will normally be in excess of 45° and in the British Isles such large sectors could include directions with vastly differing air-mass tracks.

The results are also more difficult to interpret if wind speed data are not used. For example, a decrease of westerlies if accompanied by a decrease of mean wind speed could appear as a temperature trend arising from different mixing depths both in the atmosphere and the hydrosphere.

Broad classifications of air masses (see, for example, Belasco[12]) may be expedient, but to include, within one weather-type, synoptic patterns which differ at some distance from the station under study and in recent synoptic history, is an unsound procedure on which to base the conclusion that Dzerdeevskii's hypothesis should be modified.

In some circumstances, even the time unit (one month) may prove too long for this type of analysis. October may seem to be the only month with significant weather-type differences between the two periods for both maximum and minimum temperatures because there are large differences in solar elevation, and so on, between the beginning and end of that month.

The two periods studied are each eleven years long, but the solar cycle does not seem to have been considered. It has been suggested[13] that the lower frequency of westerly types over Britain during 1931–60, compared with 1901–30 (refs. 13–15), is related to the higher level of solar activity or larger amplitude sunspot cycles in the later period. These changes of the general circulation and sunspot regime may be associated with changes of, for example, sea temperature and consequently of within-type temperature trends. Any such weather–sunspot relationship could thus be considered by using longer, consecutive series, as previously recommended.

"Weather-type" Frequencies and Temperature Fluctuation: a Reply

Lawrence's information on possible factors affecting the temperature record at Eskdalemuir Observatory, which we had unfortunately overlooked, is appreciated. It is, however, difficult to find suitable neighbouring stations, with homogeneous data series in a conveniently available form. With respect to the possible shelterbelt effects, the tendency would be towards higher maxima and lower minima in 1957–67 than in 1925–35. In fact, for anticyclonic type, which should best reflect this influence, the maxima and minima increase or decrease together in all four months investigated.

We regret the typographic errors in the two algebraic expressions in the paper. We should also like to note that the expression given for a temperature change within type (ΔT) implies no frequency change. This component should properly be evaluated from $\Delta T_A F_{1(A)}/N$. The recalculated values reinforce the view that changes in type frequency are the dominant factor in the temperature changes in January only.

We should make clear that the study was based on the original Lamb catalogue[1]. The revised catalogue, made available to us by Lamb, is being used in our further work. The need for investigation of the local weather characteristics of the types and (in our opinion) for linking the types with a suitable index of upper airflow has been referred to elsewhere[2,3]. Nevertheless, we consider that any attempt to devise a special, "local" catalogue of types, and smaller wind sectors, would create more problems than it would solve. The extent to which any one of the Lamb types may differ, from one period to another, with respect to the synoptic history of the airstreams involved, is worth studying. We have assumed that, for moderate-sized samples, there would be no systematic differences caused by track directions.

The two periods we selected were related to the recent peak and trough in the frequency of westerly type. Our initial aim was to assess the significance of this decrease in westerly airflow because many of the changes in Britain's climate since the 1930s have mainly been attributed to this factor[4,5]. As we stated, examination of the various influences which may effect within-type changes will be made when studies for other stations (and other weather parameters) have been completed.

Directional Correlation Studies of Anomalous Water in Carbonic Anhydrase

THE technique of γ-ray directional correlations has recently been applied to biological macromolecules in solution[1]. We report here the use of this technique to study internal fields of water associated with hydrated dry proteins. We chose the nuclide ^{133}Cs, which is formed by the electron capture decay of ^{133}Ba ($T_{\frac{1}{2}} = 7·3$ yr). The 356–81 keV γ-ray cascade in this nuclide involves an intermediate level of nuclear spin 5/2 and half life $T_{\frac{1}{2}} = 6·3$ ns, and has been studied previously[3-7]. The results show that $A_{44} \ll A_{22}$ in the directional correlation function and the coefficient A_{22} may be found by measuring the anisotropy.

A 100 μCi sample of ^{133}Ba in 6 M HCl (New England Nuclear) was dried over NaOH and KOH pellets in vacuum. The radioactive film was dissolved in a solution of bovine carbonic anhydrase (150 mg/25 ml. deionized water) yielding a solution of final *p*H 6·5 which was frozen with liquid nitrogen and lyophilized to constant weight. The freeze-dried samples were then adjusted to approximately 5 per cent and 20 per cent water content by exposure to 0·2 and 0·6 relative vapour pressures, respectively. The samples were placed in sealed glass cylinders (internal diameter 0·4 cm; length 8·0 cm). Measurements of enzymatic activities of these samples showed no change with respect to the original enzyme preparation.

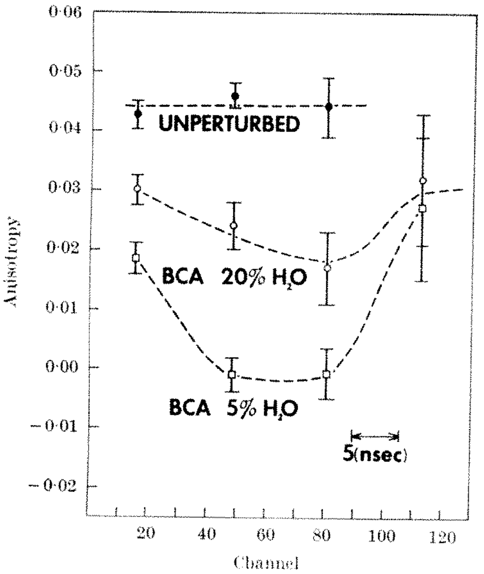

Fig. 1. Time dependence of anisotropy for 356–81 keV gamma cascade decay of ^{133}Cs in hydrated bovine carbonic anhydrase (BCA). Unperturbed anisotropy from ^{133}Cs in aqueous 6 N HCl solution.

The time dependent anisotropy of the 356–81 keV gamma–gamma cascade was measured by use of a two-detector time-differential coincidence system. Calibration of the time-to-amplitude converter was achieved by using known delay lines. A coincidence time resolution of 10 ns full width half maximum was measured by using annihilation radiation from the positron decay of ^{22}Na. The accidental coincidence rate was measured by using two isolated sources of ^{133}Ba. The anisotropy was found to be perturbed over a 40 ns time interval for both hydrated protein samples. The results (Fig. 1) are uncorrected for finite solid angle and are the result of weighted averages over the time resolution of the coincidence system.

The coefficient A_{22} was measured by performing an unperturbed directional correlation experiment. An 80 μCi sample of ^{133}Ba in aqueous 6 M HCl was used to minimize hydrolysis. Brownian motion in the solution eliminates the effects of perturbing fields and the unperturbed coefficient A_{22} may be measured. The time dependence of the anisotropy was measured as in the perturbed experiments. The result is shown in Fig. 1 and indicates no perturbations over time delays of 20 ns. The coefficient A_{22}, when corrected for finite solid angle, is found to be $A_{22} = 0·035 \pm 0·002$, in fair agreement with previously published results[3-7].

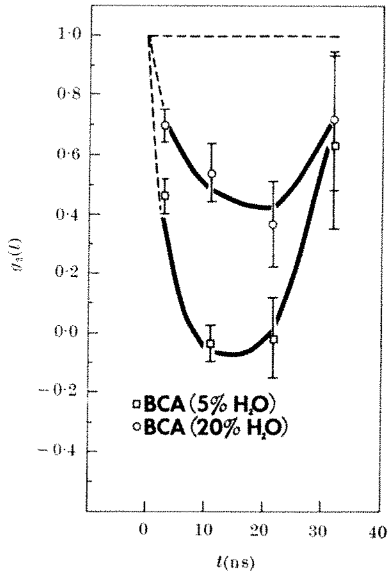

Fig. 2. Experimental perturbation factors with theoretical fit, for 356–81 keV gamma cascade decay of ^{133}Cs in hydrated bovine carbonic anhydrase (BCA).

The time dependent perturbation factors for both carbonic anhydrase samples are shown in Fig. 2. For the 5 per cent hydrated sample the behaviour of $g_2(t)$ indicates the presence of a static electric quadrupole interaction. The theoretical perturbation factor for such an interaction has been calculated[8] for an intermediate nuclear level spin of 5/2. A least-squares fit with theoretical curves corrected for finite time resolution shows the perturbation in the 5 per cent hydrated source to be caused by an axially symmetric electric quadrupole interaction which corresponds to an interaction-frequency of $\omega_0 = (2·09 \pm 0·04) \times 10^8$/s. This represents an interaction strength of $|Q\nabla E| = (9·14 \pm 0·18) \times 10^{-7}$ V. Because static fields are not expected in an aqueous dilute solution, it seems likely that the ^{133}Ba ions are occupying definite sites of axial symmetry in the carbonic anhydrase molecules. The data further indicate that all ^{133}Ba ions occupy equivalent sites, for the existence of several different interaction strengths would result in a damping of the oscillatory behaviour[8] of the perturbation factor: no such damping occurs.

For the 20 per cent hydrated carbonic anhydrase sample the behaviour of $g_2(t)$ again indicates the presence of a static interaction. At a time delay of 31 ns the directional correlation is indeed close to its unperturbed value. A comparison with the perturbation factor for the 5 per cent hydrated sample of carbonic anhydrase suggests the presence of a time dependent interaction which is seen by a certain fraction of the ^{133}Ba ions while the remainder occupy sites in the protein molecule and see only a pure static electric quadrupole interaction. If a fraction n_1 are influenced by static fields and a fraction n_2 by time dependent fields, the total perturbation factor will be given by

$$g_2(t) = n_1 g_{2s}(t) + n_2 \, e^{-\lambda_2 t} \qquad (1)$$

where $n_1+n_2=1$ and both $g_{2S}(t)$ and $e^{-\lambda_2 t}$ are corrected for finite time resolution. The static perturbation factor g_{2S} is known from the 5 per cent hydrated source. Equation (1) was solved numerically for several values of n_1, n_2 and λ_2. A best fit of the data gives $n_1=0{\cdot}45$, $n_2=0{\cdot}55$ and $\lambda_2=(8{\cdot}20\pm1{\cdot}00)\times10^6$ s^{-1}.

If the fraction n_1 of the ^{133}Ba ions are attached to the carbonic anhydrase molecules, then the fraction n_2 must be in the water associated with the molecules. If the water is normal, with a correlation time $\tau_c\simeq10^{-11}$ s, then time dependent interactions should not be observable. If the water is anomalous (that is, ordered) with a rotational correlation time much larger than 10^{-11} s, time dependent interactions become possible due either to fluctuating fields in the water or to the propagation of the electron hole following the electron capture decay of ^{133}Ba. It is suggested that the fraction n_2 of the ^{133}Ba ions are in the anomalous water associated with the carbonic anhydrase molecules. A relaxation time for this environment may be obtained from λ_2. We find $\tau=1/\lambda_2=(1{\cdot}22\pm0{\cdot}15)\times10^{-7}$ s, which indicates that the water associated with carbonic anhydrase molecules is highly ordered.

We thank D. Christy and G. Tollefson for their help in the experiments. This work was supported in part by the Research Corporation.

Luminescence of Photoproducts at Defects in a Doped Inert Matrix

THE importance of defects in solid state reactions is well known[1] and the possibility of the direct observation of photochemical reactions at defects is of interest. Cohen *et al.*[2] irradiated a single crystal of acenaphthylene with ultraviolet light and produced a photodimer product located at the crystal defects. Unfortunately, host and reactant are the same species and the question remained whether the photoproduct migrated to the defects or was formed at the defects.

We have also observed photoproducts associated with crystal defects, but we used a two-component system which differs in important respects from that of Cohen *et al.* They used a host crystal entirely composed of photoactive aromatic molecules, which absorb ultraviolet light, react and luminesce. The host material we used is cyclododecane (CDD), which is transparent and photoinert. The CDD is deliberately doped with photoactive aromatic molecules and the distribution of guest aromatic molecules has been investigated[3] for single crystals grown by the Bridgman–Stockberger method (Fig. 1). D. J. M. and Mathur[3] have shown that, for phenanthrene concentrations up to 5×10^4 M, the distribution is in cellular patterns and probably monomolecular. Phosphorescence lifetime measurements[4] demonstrate a monomolecular dispersion below these concentrations. At higher concentrations precipitation occurred at defects. A CDD lattice vacancy is at least $8{\cdot}5\times8{\cdot}5\times4$ Å and can just about accommodate a phenanthrene molecule in a diagonal aspect, the latter having dimensions approximately $11{\cdot}6\times8\times3{\cdot}2$ Å.

We prepared samples by outgassing a mixture of CDD and phenanthrene in a tube under vacuum. The tube was sealed, the mixture molten and re-solidified. The tube was then broken to yield a gas-free solid sample. This was sandwiched between two quartz slips on a hotplate, gently heated until the CDD melted and some liquid was ejected at the sides. The centre portion, which remained, was cooled slowly. Several single crystal regions were observed to form.

On irradiating 5×10^{-3} M samples an induction period of 5 min was followed by a growth of the fluorescence

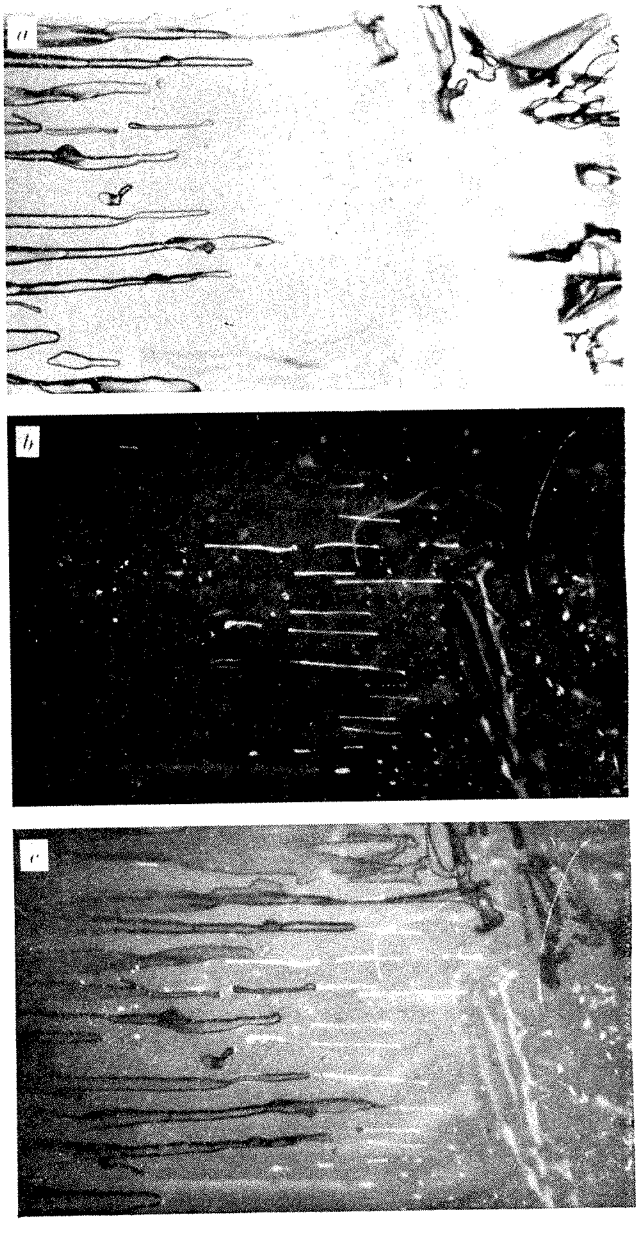

Fig. 1. Low power photomicrograph of phenanthrene doped cyclododecane crystal. *a*, Under transmitted white light; *b*, under 365 nm radiation from beneath sample; *c*, under mixed ultraviolet irradiation and transmitted light.

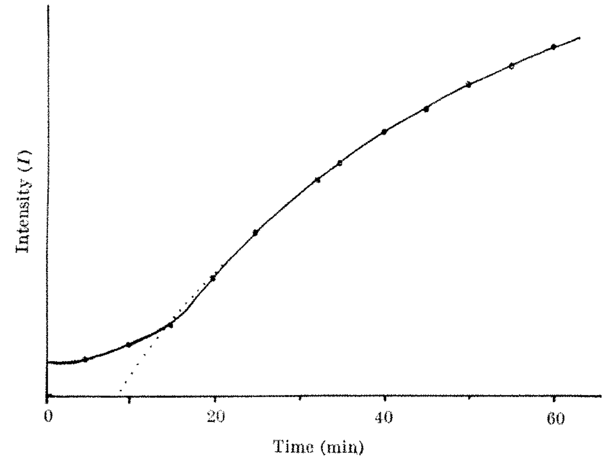

Fig. 2. Relative fluorescent intensity (I) of defect material as a function of time (t). The dots represent the closest fit of an exponential curve.

intensity, I, to a maximum I_0 (Fig. 2) according to the relationship

$$I = I_0\,[1 - \exp(-kt)]$$

where t is the time elapsed after the induction period. We measured the intensity at 450 nm, which is the band maximum (Fig. 3) for the fluorescence. The phenanthrene band was determined by overdoping until precipitation occurred and also using small phenanthrene crystals; this peaks at 435 nm (Fig. 3). Observations at 435 nm showed an initial rapid decrease during the induction period. An initial reaction with impurity, probably dissolved oxygen, until the latter is depleted is suggested. The exponential term suggests a first order decay of reactant, so that polymerization is not likely to an extent beyond dimerization. We attempted to characterize the reaction product by thin-layer chromatography. Spots were prepared of pure phenanthrene; doped CDD not irradiated; and doped CDD irradiated, each dissolved in 3-methylpentane, using n-heptane as the solvent. The chromatogram was run for 10 cm and the result is shown in Fig. 4. The positions of the phenanthrene and of the CDD showed, under 253·7 nm light, as a blue fluorescence and as a whitish patch respectively. The spot corresponding to phenanthrene showed no signs of impurity and that corresponding to non-irradiated doped CDD showed no signs of a third component. The irradiated sample showed both CDD and phenanthrene, as well as a new component which appeared as a streak between the baseline and the phenanthrene spot. The R_F value of the photoproduct, being lower than phenanthrene, suggests that it may be a larger molecule than phenanthrene or possibly a polar oxidation product.

The advantages of the system we used derive from the fact that only the guest and its photoproducts are photoactive. Thus we are able to use transmission microscopy techniques and we can observe the photoproduct by its own luminescence unimpeded by host absorption or emission.

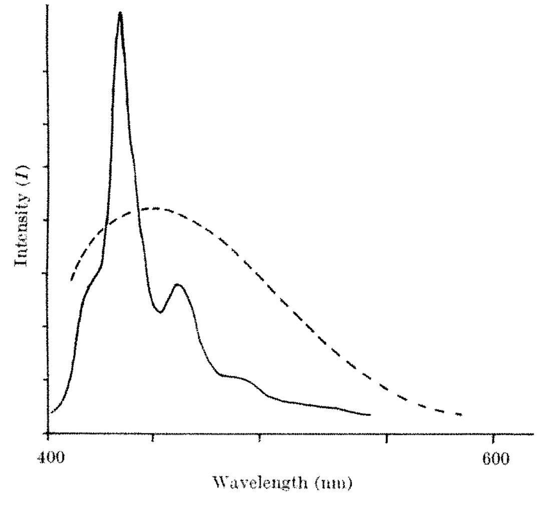

Fig. 3. Emission spectra observed through the microscope. - - - -, Emission from defect material: ——, emission from precipitated phenanthrene in a concentrated sample.

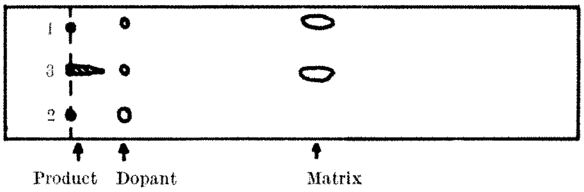

Fig. 4. Schematic representation of a chromatogram, viewed under ultraviolet light. The trace obtained from non-irradiated phenanthrene sample (1) shows two components. The trace for phenanthrene only (2) shows one component. The trace for an irradiated sample (3) shows new components as a streak.

The imperfections we observed included planes and cracks which run perpendicular to the plane of the quartz plates. The cracks developed at the termini of the defect planes as the crystal grew. We also observed these features in a pure, undoped, CDD sample using interference microscopy. The defect planes probably arise from the release of internal stresses set up by contraction as the material solidifies. The planes and cracks are unequivalent, not only in their morphology but in their fluorescence behaviour. We cannot dismiss these distinctions. It is unreasonable to expect photoproduct to migrate to defect planes and not to cracks. We may expect, on the other hand, that the phenanthrene is aggregated in defect planes and probably also on the cracks. We can assume that some traces of oxygen are present in the crystal which are exhausted in the planes during the induction period. Sufficient oxygen may be present in the free spaces in the cracks so that photooxidation occurs there throughout the irradiation period.

The appearance of the planes is regular and flat, contrasting with the cracks. We believe these to be defect planes in which the phenanthrene may be orientated in thin layers. These planes must, in any event, be dense enough to inhibit oxygen diffusion. Ferguson[5] has shown that excimer emission occurs in cyclohexane crystals at 77 K and considers that the crystal host provides orientation conditions which favour excimer formation.

Recalling that the reaction could be considered as first order, we may envisage that after the absorption of a photon by one of the phenanthrene molecules it forms an excimer which reacts, or alternatively it reacts directly to form a dimer. This can occur between adjacent pairs of molecules in a monolayer until it is depleted.

Observation of Substructures in Photoinert Organic Single Crystals doped with Photoactive Impurities

THE photoexcitation properties of organic crystals have generally been studied for pure or mixed aromatic single crystals. In these cases the host is photoactive[1–3]. The substructures of such molecular crystals are not as well known as in the cases of ionic[4] and metallic crystals[5], although such structures may well influence the properties involved in photoexcitation. D. J. M. and Irons[6] used cyclododecane (CDD) single crystals as the photoinert host for phosphorescence lifetime studies of the photoexcited triplet state of dissolved aromatic impurities. Lifetime variations were found and these were attributed to various states of aggregation of the photoactive solute species in the single crystal host. The tendency to aggregate was correlated to lattice mismatch between host and dopant molecular dimensions. The present work establishes the presence of aggregates in doped single crystals of CDD (cyclododecane) by direct observation.

Doped crystals of organic materials grown by the Bridgman–Stockberger method[7,8] contain large numbers of imperfections[9,10]. During the unidirectional freezing of the two component system, the solute distribution ahead of the solid/liquid interface is, of necessity, not uniform. Instead, a concentration gradient is formed which violates the condition for the stability of planar solid/liquid interfaces. This leads to constitutional supercooling and impurity substructures[11,12]. We have indeed observed, in CDD crystals, the pox and cellular structures commonly found in constitutional supercooling and have also studied the effect of the nature and amount of the solute content on the microstructure of a CDD single crystal. The CDD was purified, and doped crystals grown as described elsewhere[6]. The aromatic phosphor impurities were added in weighed amounts, to yield concentrations of 10^{-2} M in the melt with respect to the host material. The concentrations which result in the crystal were lower by one or two orders of magnitude. The grown crystal was sectioned parallel to the growth direction. We used a "chemical" saw which was dipped every now and then in a suitable solvent such as carbon tetrachloride. A smooth crystal surface was obtained for optical microscope examination by grinding on a flat glass paper. This was followed by further polishing using a tissue paper, which was soaked in CCl_4 and placed on a flat glass plate. The crystal was then dipped in CCl_4 for 5 s and washed briefly with absolute alcohol. Finally, the crystal was etched with absolute alcohol for 3–5 min and subsequently examined by standard optical methods.

We have observed network structures characteristic of constitutional supercooling. Fig. 1 shows a transmission photomicrograph of CDD doped with phenanthrene (melt concentration 10^{-2} M, concentration in crystal 5×10^{-4} M); the growth direction is parallel to the plane of the photomicrograph. The photograph shows the cell nodes, preferentially etched, which resulted from constitutional supercooling. The nodes are reliable indications of the solute distribution. We confirmed this through the bulk of the crystal by observations of the same sample using fluorescence microscopy. Fluorescent spots, attributable to phenanthrene, were seen distributed through the bulk in similar cellular patterns. These latter observations were made possible by the transparency of the host crystal. While advantage can be taken of transparent hosts for ionic species[4] and for infrared transparent[13] crystals, this is not possible in the case of aromatic single crystals where the whole of the matrix will absorb ultraviolet. This problem has been overcome in an interesting way by Cohen, Ron, Schmidt and Thomas[14], who produced photodimers in a thin aromatic single crystal, presumably at dislocations, and who observed the resulting fluorescence at dislocations. This last method provides, to our knowledge, the only other method to the one we report here for the observation of dislocation networks in a bulk organic crystal. A similar effect, using doped photoinert CDD crystals, has also been reported and characterized by D. J. M. and Miles[15].

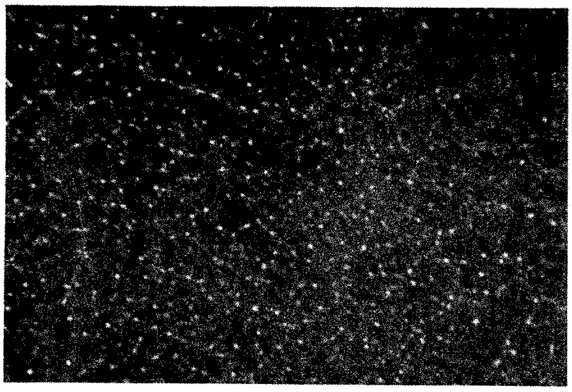

Fig. 1. Photomicrograph of phenanthrene doped CDD (×60) showing cell nodes, preferentially etched.

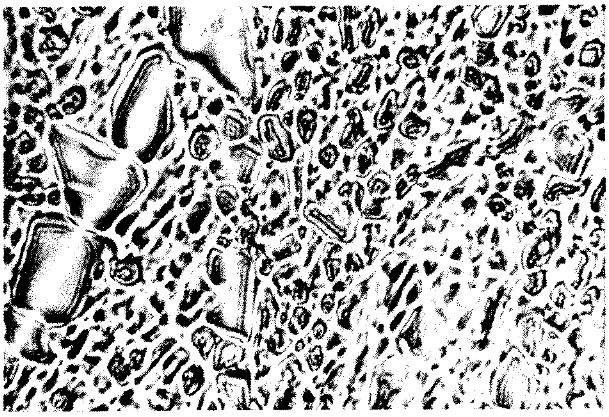

Fig. 2. Photomicrograph of triphenylene doped CDD (×400) showing a microsegregation "necklace" across the upper left hand corner.

We have studied the constitutional supercooling process by varying the molecular parameters of the solute, using the same growth and concentration conditions as for Fig. 1. Fig. 2 shows a transmission photomicrograph for a triphenylene sample and, in this case, we see microsegregation of the triphenylene as well as a cellular structure. This microsegregation behaviour was not seen in any of our phenanthrene samples at the same concentration. The microsegregation evidently arises from lattice mismatch as predicted by D. J. M. and Irons[6], while mismatch between phenanthrene and CDD does not occur. When, however, the concentration of the phenanthrene was increased to 5×10^{-2} M in the melt, well characterized precipitation did occur. The precipitated microcrystals of solute were observed by transmission microscopy and also by means of their fluorescence under ultraviolet excitation. Using a melt concentration of 10^{-2} M, which is the same as for Fig. 1 and Fig. 2, chrysene doped CDD gave precipitates only, and we have not seen cellular structures for chrysene in CDD crystals.

We have observed that cellular structures occur from the aromatic dopants we have studied only where solubility of the dopant in the host is assured by matching molecular dimensions. An apparent exception is the case of benzil which also yields cellular structures and, as noted by D. J. M. and Irons, the benzil molecule dimensions can be

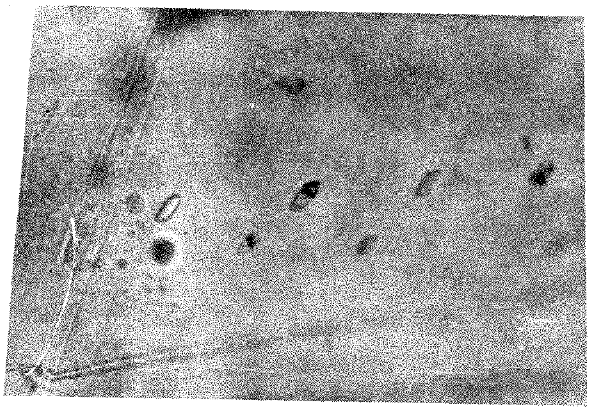

Fig. 3. Photomicrograph of phenanthrene doped CDD (5×10^{-2} M in the melt) showing precipitation of phenanthrene.

matched by a pair of CDD molecules. The tendency to precipitate appears to be related to the lattice mismatch through the segregation coefficient. The tendency to precipitate increased in the following order: phenanthrene < carbazole < triphenylene < chrysene. This order corresponds to increasing lattice mismatch. We expect this order to be inversely related to the segregation coefficient and preliminary work indicates that this is so. The similarity in the cellular structures observed in CDD organic crystals to those seen in alloys is not surprising, but merits comment. In both cases the passage from a soluble to an insoluble condition will depend on physical factors, namely, the solubility and growth parameters. The hexagonal appearance of the cells corresponds to a close packed arrangement consistent with a maximum ratio of cellular content to cellular surface.

BIOLOGICAL SCIENCES

Timing of Neuroblast Multiplication in Developing Human Brain

As a result of experimental studies using growing rats[1] and pigs[2], it has been established that the developing brain is most vulnerable to restrictions such as undernutrition at the time of its fastest growth. Restriction at this time need not be severe to produce permanent deficits. This vulnerable period, the so-called brain "growth spurt", varies considerably between species only in its timing in relation to birth[1]. It has thus become desirable to define it for the human species and we report here part of an extensive quantitative study of human brain growth undertaken to this end.

Brains were obtained from twenty-four human embryos resulting from therapeutic abortion as well as from a series of stillbirths and perinatal deaths. The abortion material from 10 to 22 weeks of gestation has all been considered normal, and its gestational age estimated from the menstrual history and the foetal size. The later autopsy material, comprising fifty-two cases, was selected on the basis of the birth weight being within one standard deviation of the mean for the gestational age[3] and having no gross cerebral or other pathology. Total cell numbers were estimated by chemical analysis[4] of DNA–P in the forebrain, cerebellum and brain stem, and the whole brain values calculated as the sum. The relatively small number of tetraploid cells in the normal brain[5] were not considered to influence the assumption that total tissue DNA represented total numbers of cells. It was also established, by the use of freshly killed rat brain, that the quantity of DNA was unaffected by the inevitable delay between death and the collection of the human material.

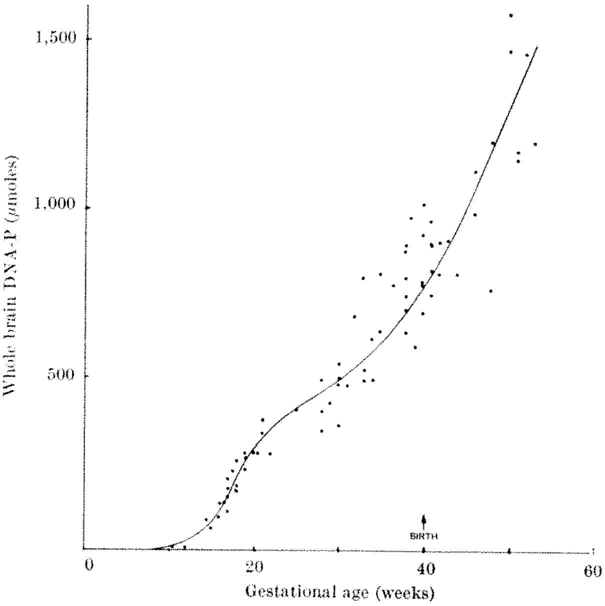

Fig. 1. The increase of whole brain DNA in developing human brain.

Fig. 1 illustrates the new finding that there are two major periods of cellular multiplication in human brain: one from 15–20 weeks of gestation and one which commences at about 25 weeks of gestation. This second period probably ends in the second year of postnatal life. The previous failure[6,7] to detect the earlier period can be ascribed to an insufficient number of cases for analysis at the relevant gestational age. The failure to detect the same events in studies of animal brain development presumably results partly from the difficulties imposed by a much faster developmental time scale in small laboratory species and partly from a failure to collect sufficient specimens at an early enough age.

Fig. 2 shows the result of plotting the logarithm of the DNA–P value against the age, and treating the samples between 10 and 20 weeks separately from the later material. It is clear that two distinct phases of cell division exist, each with different exponential characteristics.

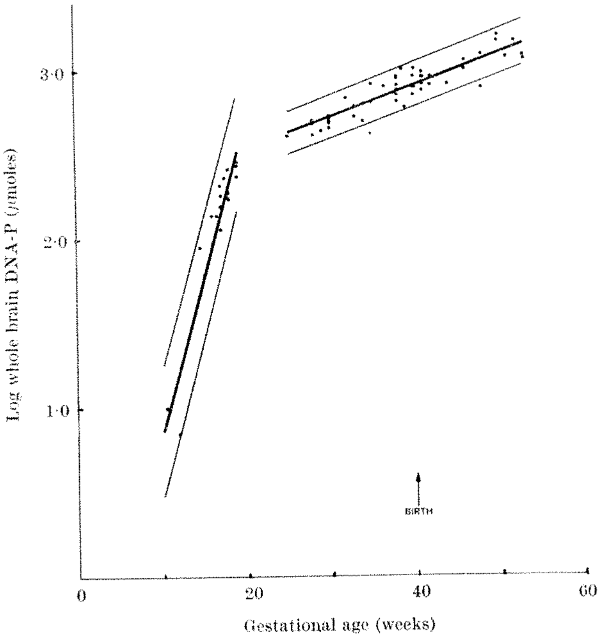

Fig. 2. The logarithm of whole brain DNA in developing human brain. Regression lines and their 95 per cent tolerance limits have been calculated to illustrate the two phases of cell multiplication (see text). First phase: Log whole brain DNA–P_{10-19} = − 0·9830 + 0·1845 × age. Tolerance limits ±0·3886. Second phase: Log whole brain DNA–P_{25-33} = 2·1555 + 0·0188 × age. Tolerance limits ±0·1325.

It is well known that the adult number of neurones is achieved quite early in brain development, before the phase of glial cell multiplication begins[8]; and that glia in the adult brains of large species outnumber neurones by several fold[9]. From this it seems likely that the first phase of multiplication reported here, occurring from 15–20 weeks of gestation, represents the period of neuroblast proliferation. The same phenomenon has also been found in the increase of DNA in the human forebrain and cerebellum. In both regions the timing is identical to that shown in Figs. 1 and 2. The second phase must predominantly represent glial division.

Undernutrition restricting growth at the "vulnerable period" defined here produces an ultimate cell deficit in the adult which is probably mainly glial. Whether earlier restriction applied during this newly discovered first period of DNA increment would lead to greater behavioural impairment is now being investigated.

We thank our colleagues for help in obtaining the specimens. The work was supported by a grant from the Medical Research Council and help from the National Fund for Research into Crippling Diseases.

Space–Time Transformation in the Frog Cerebellum through an Intrinsic Tapped Delay-line

THE cerebellum is interesting for the arrangement of its neurones in a symmetrical three-dimensional lattice, with only two classes of input fibres and one of output fibres[1]. This arrangement led Braitenberg[2] to postulate a set of logic operations that the cerebellar cortex might perform. One postulate was that, by virtue of the distribution of the "output" neurones (Purkinje cells) at regularly spaced intervals along beams of parallel fibres (Fig. 1*A*), the cerebellum might function as a type of clock, transforming an event that occurred at some peripheral spatial location into a temporal event. A central assumption of this hypothesis is that the time of firing of a Purkinje cell is determined by the conduction time of afferent impulses travelling in parallel fibres from some reference point on the beam of parallel fibres on which it lies to the Purkinje cell. If this assumption is correct the parallel fibre–Purkinje cell system would constitute a tapped delay-line[2–4]. If the reference point is the position of another Purkinje cell along the beam, then a corollary is that the time between the firing of the two cells must be equal to the conduction time of the segment of the beam connecting them.

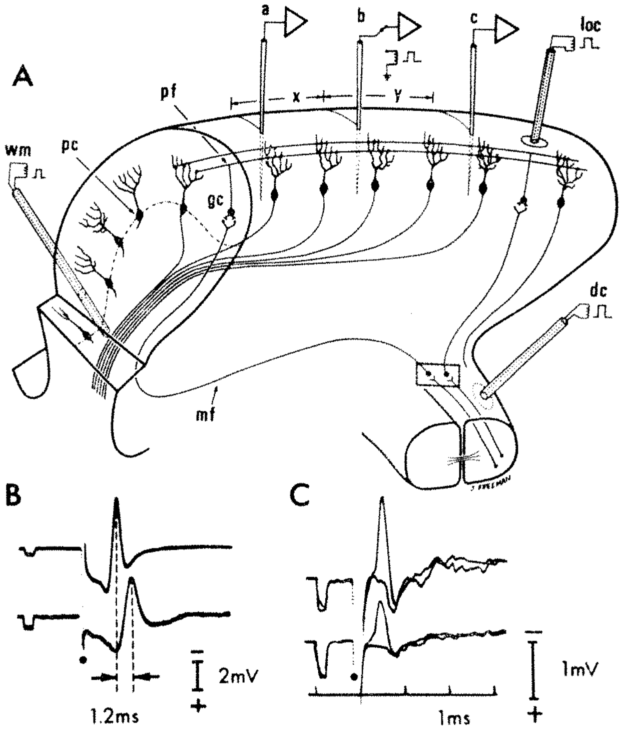

Fig. 1. *A*, Diagram of frog cerebellum and experimental arrangement described in text. pc, Purkinje cell; gc, granule cell; pf, parallel fibre; mf, mossy fibre. *B*, Extracellular field potentials evoked by surface stimulation recorded simultaneously at two different points 250 μm apart on the same beam of parallel fibres. Conduction time of the parallel fibres between the two electrodes is indicated by arrows. *C*, Simultaneous extracellular recording of a pair of Purkinje cells activated antidromically. Two superimposed sweeps (stimulus intensity greater and less than threshold) revealing an all or none response.

Because time is a crucial parameter in the coordination of muscular activity—a presumed function of the cerebellum—Braitenberg's hypothesis has been of considerable interest, although it has never been tested. One apparent difficulty is that the mossy fibres branch extensively when they enter the cerebellar cortex[5]. If the branching were such that two Purkinje cells lying on the same beam of parallel fibres were activated by parallel fibres arising at multiple points randomly distributed between them, then the delay between their firing would vary randomly, and Braitenberg's hypothesis would fail. This motion was tested by computing the degree of correlation between the firing of two (and sometimes three) simultaneously recorded frog Purkinje cells lying on the same beam of parallel fibres.

Bullfrogs (*Rana catesbiana*) were immobilized with 4 mg/kg of *d*-tubo-curare, the tissues overlying the skull were anaesthetized with 'Procaine' and the cerebellum was exposed. The animals were placed on a small rotatable platform, to provide natural vestibular stimulation. The trajectory of a beam of parallel fibres was determined by activating the beam with a surface stimulus applied near one side of the cerebellum (Fig. 1*A*, "loc"), and tracking along it with a pair (or triplet) of microelectrodes (micropipettes filled with 4 M NaCl for extracellular recording *a*, *b* and *c*, Fig. 1*A*). Electrode positions were adjusted individually until the field potentials generated in response to the parallel fibre stimulus were maximal. In thirty-six frogs the parallel fibre conduction velocity *v* (computed by dividing the distance *x* between electrodes by the time between the peak negativity of the field potentials[6] (Fig. 1*B*)) was 20 ± 2 cm/s. This value was quite uniform over the width of the cerebellum for a given frog. Purkinje cells were identified by being activated antidromically (by stimulation of their axons with an electrode placed in the cerebellar white matter (Fig. 1*A*, "wm"))[7]. All or none antidromic responses from two simultaneously recorded Purkinje cells are shown in Fig. 1*C*.

To determine the degree of correlation between two cells, a LINC-8 computer was used to compute first order serial correlation[4] ("cross interval"[8]) histograms, that is the distributions of times from an action potential produced by one cell, to the first preceding and following action potential produced by the other cell. This analysis can reveal some additional important characteristics of the mossy and climbing fibre inputs to the cerebellar cortex. For example, consider two Purkinje cells separated by a distance *x*: because of their uniform conduction velocity *v*, parallel fibres which arise outside the zone *x* will tend to cause them to fire at a single, fixed interval, *x*/*v*, producing a peak at the same interval on the histogram. A pair of peaks, symmetrical about the origin, will be produced if parallel fibres arising on both sides of the zone *x* are activated. On the other hand, parallel fibres arising between the cells tend to cause them to fire at an interval proportional to the relative distance from the parallel fibre branch points to the two cells. The positions of any peaks on the corresponding histograms therefore reveal the locus of predominant parallel fibre activity. Finally, if (*a*) parallel fibres synapsed with one, but not both cells, or fired asynchronously in response to the activation of mossy fibres, or (*b*) the two cells were activated predominantly by their separate climbing fibre inputs rather than by their shared parallel fibre inputs, they might fire in an uncorrelated manner, producing a histogram which decayed exponentially from a maximum value at the origin[4].

Forty-eight pairs of Purkinje cells were analysed. The records on one pair, 150 μm apart, are shown in Fig. 2. The sharp peak at 0·75 ms in response to parallel fibre stimulation (Fig. 2*A*) shows clearly the sequential activation of the two cells as the volley travelled from one to the other. During angular acceleration both cells responded with a sustained burst of spikes (Fig. 2*C*), and, as shown by the prominent peak at 0·75 ms in Fig. 2*B*, they fired in the same sequence and at the same time intervals which would be produced by unidirectional activation of the beam of parallel fibres connecting them. Similar correlated firing was observed in thirteen pairs of cells in response to angular acceleration, and in forty-one pairs in response to stimulation of the spinal cord (*d*, *e* in Fig. 1*A*), and of the sciatic and radial nerves.

Two types of experiments proved that the correlation in times of firing was mediated by the parallel fibres connecting the cells. A current source-density analysis[9] revealed that the parallel fibres were activated synchronously by the same stimuli that caused the cells to fire in sequence; whereas blocking the conduction of parallel fibres between the cells (by a collision technique[4]) abolished the correlation.

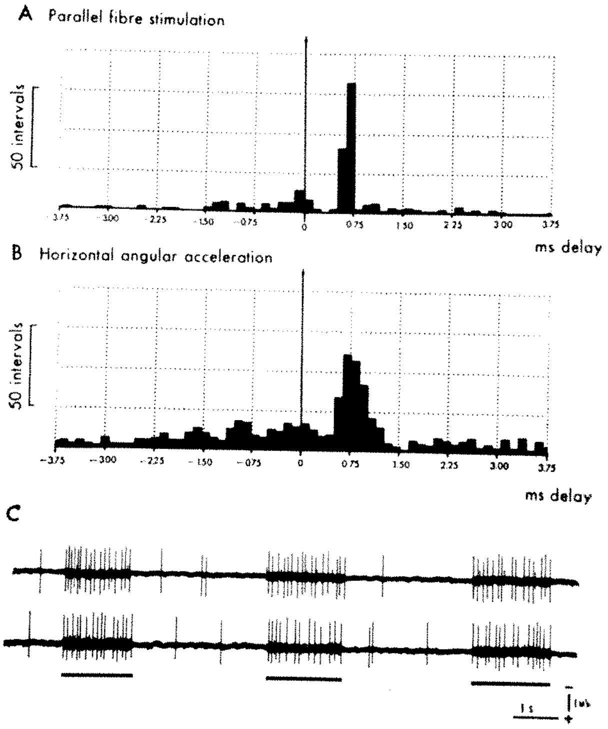

Fig. 2. Correlation between times of firing of two Purkinje cells on the same beam of parallel fibres. *A* and *B*, First order serial correlation histograms computed during stimulation of the beam of parallel fibre connecting the two cells (100 stimuli, 1 stimulus/2 s) and during horizontal angular acceleration (approximately $2^{\circ}/s^2$), respectively. Peaks at 0·75 ms in both records show that the firing of the two cells was correlated: cell *X* (lower record in *C*) tended to fire at a fixed interval after cell *Y* (upper record in *C*) equal to the conduction time along the beam of parallel fibres connecting them. *C*, Single unit records of the two simultaneously recorded Purkinje cells during horizontal angular acceleration (indicated by the horizontal line).

The time between the firing of two Purkinje cells increased linearly with increasing distance between the cells. By contrast, in only one pair of cells was correlated firing observed during spontaneous activity (these cells were only 50 μm apart); and in fifteen pairs of cells which lay "off beam" no correlation was found.

These results suggest that in the frog (1) geometrical specificity is preserved in the distribution of mossy fibre terminals, in spite of their extensive branching; (2) a substantial number of the parallel fibres connecting a row of Purkinje cells fire in synchrony in response to some natural and electrical stimuli; (3) during this type of stimulation, the Purkinje cells fire predominantly in response to their parallel fibre rather than to their climbing fibre input; (4) peripheral events are represented both temporally and spatially in the cerebellar cortex, in the sense that simultaneous events, or aspects of a single event, in the external world can be coded as a temporal sequence of activity in a discrete population of Purkinje cells; conversely, an external event occurring at a particular time can be coded as a spatial sequence of Purkinje cell activity, and (5) in response to some natural stimuli, the parallel fibre system functions as a physiological tapped delay-line, distributing excitation in a precise temporal sequence along rows of Purkinje cells.

Effect of Pretreatment with Oestradiol, Progesterone and DOPA on Monoamine Oxidase Activity in the Rat

THE enzyme monoamine oxidase (MAO) (EC 1.4.3.4), which is widely distributed in the animal kingdom, is probably involved in the *in vivo* inactivation of a number of biologically active monoamines of physiological importance although its precise function has yet to be defined. Its putative role in the pathogenesis of mental disease has tended to focus interest on the brain in recent years, rather to the exclusion of other anatomical sites. J. S. *et al.*[1], however, have lately drawn attention to a variant of this enzyme present in human endometrium which undergoes sharp changes in activity during the different phases of the menstrual cycle. Although there is some evidence to suggest that such cyclical variations do not occur outside the female genital tract in the human[2], small fluctuations of enzyme activity have been noted in several rat and guinea-pig tissues during the oestrus cycle[3-7]. The most likely explanation for all these changes must presumably be based on alterations in hormonal levels, and to investigate this possibility we sought to influence the MAO activity of rat tissues by pretreating the animal with oestradiol and progesterone. Although hormones such as these may mediate the observed changes, the available data do not shed any light on how direct is the cause and effect relationship. There may be intermediate stages in the train of events leading to alterations in enzyme activity. A number of reports[8,9] point to variations in tissue concentration of amine substrates of MAO during the phases of the oestrus cycle. It is possible therefore that physiologically occurring cyclical increases in MAO activity might represent an adaptive response to increased availability of substrate. We have attempted to evaluate this possibility indirectly by treating rats before enzyme assay with DOPA which leads to increased tissue levels of the MAO substrate, dopamine.

Twenty-four 120–150 g female white Wistar rats were divided into four groups of six animals; one group was injected subcutaneously on three consecutive days with 3·3 mg/kg progesterone and another with 3·3 mg/kg oestradiol for a similar period of time. A third received 100, 150, 200 and 300 mg/kg DL-DOPA intraperitoneally on four consecutive days while the remaining group was given 0·9 per cent (w/v) NaCl solution, 0·25 ml. subcutaneously and 0·75 ml. intraperitoneally, for three consecutive days. On the day after completion of treatment, animals were killed by dislocation of the neck. Tissues were removed, freed from connective tissue, weighed and stored at −20° C. They were homogenized in ice-cold 0·3 M sucrose for 1 min and centrifuged at 600*g* for 15 min to sediment the cell debris. The supernatant was spun at 17,000*g* for 30 min to sediment the mitochondrial fraction. Finally, the microsomal fraction was isolated by centrifugation at 56,000*g* for 60 min. All fractionations were carried out at 4° C. Suitable suspensions were made in phosphate buffer (0·05 M, pH 7·4) and assayed for MAO activity using kynuramine as substrate[10]. Protein nitrogen was determined[11] using crystalline bovine serum albumin as a standard. MAO activity was expressed as ng 4-hydroxyquinoline formed/min incubation/mg protein nitrogen.

Table 1. EFFECT OF OESTRADIOL, PROGESTERONE AND DL-DOPA ON RAT TISSUE MAO

	Control	Oestradiol	Progesterone	DL-DOPA
Uterus	75·0 ± 6·0	57·7 ± 6·0†	125·9 ± 8·1†	131·3 ± 10·6‡
Ovary	146·0 ± 16·0	127·3 ± 12·1	161·2 ± 23·1	131·0 ± 20·2
Heart	155·5 ± 9·8	177·5 ± 16·3	169·9 ± 14·2	123·5 ± 14·3
Brain	196·3 ± 8·2	197·6 ± 8·8	196·2 ± 16·9	190·6 ± 13·1

Sub-maxillary gland	56·9 ± 3·5	52·7 ± 2·7	54·3 ± 2·3	53·4 ± 3·6

Activities are expressed as ng kynuramine deaminated/min incubation/mg protein ± *S.E.* See text for description of the experimental procedure.

* $P < 0{\cdot}02$. † $P < 0{\cdot}01$. ‡ $P < 0{\cdot}001$.

Table 1 illustrates total MAO activity (that is, the sum of activities of cell debris, mitochondrial, microsomal and supernatant fractions) of various tissues. After oestrogen pretreatment there was a significant fall in activity in uterus and liver. Progesterone pretreatment, however, caused a significant increase in the uterus alone, and other tissues were quite unaffected. A similar specific increase in uterine MAO activity occurred after DL-DOPA treatment. Parallel changes were noted when activities were expressed per g wet weight of tissue. The general pattern of alteration in uterine enzyme activity was mirrored by all subcellular fractions (Fig. 1); the patterns for other organs did not bring out any effect of drug treatment.

Four uteri from each group were examined histochemically for MAO activity[12], as described by J. S. *et al.*[1]. Changes after oestradiol and progesterone pretreatment corresponded with the quantitative estimations (Fig. 2), whereas those after DOPA administration were less clear. MAO activity was localized mainly in the endometrium but a small constant level was also maintained in the myometrium.

The present observation that progesterone pretreatment brings about a specific increase in rat uterine MAO activity is in agreement with a hormonal explanation of our previous finding of an approximately ten-fold increase in human endometrial enzyme activity at about the

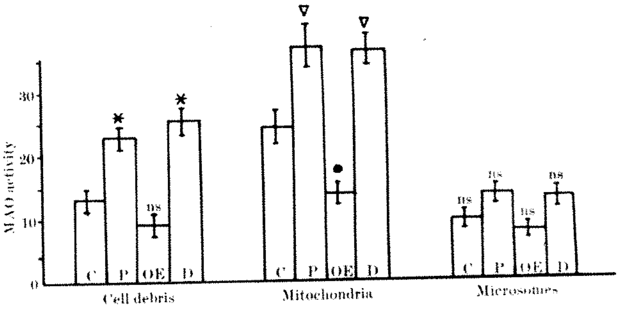

Fig. 1. Monoamine oxidase activity (expressed as ng 4-hydroxyquinoline formed/min incubation/mg protein nitrogen) of the various subcellular fractions of rat uterus. Each column represents the mean of six observations ± *S.E.* and comparisons of significant differences are made between each drug treatment and control values. Activity in the supernatant was less than 1 per cent of the total and has not been included. Fig. 2. *A*, Rat endometrium after oestrogen administration showing weak monoamine oxidase activity as scattered dye particles (nitro blue tetrazolium method × 200). *B*, Rat endometrium after progesterone administration showing strong monoamine oxidase activity. There is a diffuse dark (blue) staining of endometrium and some dye is present in fat droplets (nitro blue tetrazolium method × 200).

nineteenth to twenty-first day of the menstrual cycle[1] when plasma progesterone levels are known to be at their peak[13]. Further support is provided for this interpretation by Grant and J. P.-D.[14], who recently observed that administration of strongly progestational oral contraceptives causes a prolongation of the late secretory phase of the human endometrium accompanied by a corresponding increase in MAO activity. It may be that fluctuations of circulating hormone levels are not as marked during the oestrus cycle compared with the menstrual cycle, for rat uterine MAO undergoes no apparent change[1,3]. There have been several reports, however, of variations in MAO activity during the oestrus cycle in specific areas of rat and guinea-pig brain[3-6]; but if any such localized changes do exist, they were masked in our whole organ homogenate. Apart from the uterus, the only organ in which we could detect any change after drug administration was the liver in which, as with the uterus, MAO activity was reduced after oestrogen pretreatment. This finding is in line with similar data of Wurtman and Axelrod[15] and also correlates with a report that mouse liver MAO activity is lower during oestrus compared with pro-oestrus[7]. It is probably relevant in this connexion that cardiac MAO activity is lower in the female than the male rat[15,16]. Oestrogen dosage gave rise to an unequivocal decrease in rat uterine MAO and, although this finding might not have been predicted from the data of earlier workers[17-19], it agrees well with our previous observation[1] of comparatively low activity in the human endometrium during the non-secretory phase of the menstrual cycle.

At present, data are not available to show whether the amine concentration of the human uterus fluctuates during the menstrual cycle; in the rat uterus, however, endogenous noradrenaline concentrations are significantly raised during oestrus[8] and circulating adrenaline is accumulated more avidly during oestrus than dioestrus[9]. We have found that DOPA treatment, which increases tissue levels of dopamine[20], a good substrate of MAO[21,22], gives rise to increased uterine MAO activity either by induction of enzyme synthesis or by a more direct action on the catalytic mechanism. Whether the mechanisms of action of the drug treatments are in any way interconnected or have any physiological significance can only be decided by future experiment. One other point emerges: the MAO variant found in the uterus differs from other rat tissue MAO isoenzymes[23-25] in its sensitivity to hormones and is the subject of further intensive study. Whether progesterone which potentiates or oestradiol which inhibits activity brings about these *in vivo* changes by altering its synthesis or by some more direct mechanism has yet to be established.

Behavioural Effects of some Derivatives of Amphetamine and LSD and their Significance

In attempts to work out possible mechanisms of action of the hallucinogenic drugs, it would be helpful to know which chemical groups modify their activity. In the methoxylated amphetamines, some methoxy groups may act as electrostatic binding sites and some may effect the shape and energy distribution of the π cloud. It may also be important to know whether the amino group is necessary for activity. It has been shown that N,N-dimethylmescaline is a less potent compound than mescaline[1,2]. We have now tested further N,N-dimethyl derivatives of hallucinogenic amphetamines using the Bovet-Gatti profiles on the Sidman avoidance schedule[3,4] which we have found to discriminate between hallucinogenic drugs very well. 4-Methoxyamphetamine is a very potent disrupting drug in rats and produces a typical "hallucinogenic" profile at 3 mg/kg (equivalent to mescaline at 25 mg/kg). The N,N-dimethyl derivative was totally inactive at 25 mg/kg. 2,5-Dimethoxy-4-methyl amphetamine (DOM) is the most potent human hallucinogenic amphetamine known (active in rats at 2·5 mg/kg). Its N,N-dimethyl derivative was also quite inactive at 20 mg/kg. These results suggest that, if these compounds bond, they do so using their N atoms, in which case our hypothesis[5] would predict that the 3-compound (not yet tested) would be an active hallucinogen. The relative activity of methoxylated amphetamines seems to correlate more with their quantum chemical properties, such as their Hückel molecular orbital (HMO) energies and degree of native fluorescence[6], than with their steric properties. That is to say, the steric requirements seem to be an unhindered N and an unhindered *ortho* or *para* methoxy group, and the energetic requirement is a high HMO energy.

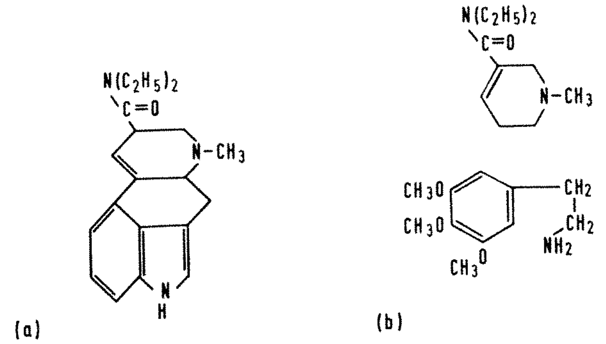

Fig. 1. (*a*) LSD; (*b*) mescaline and 1-methyl-1,2,5,6-tetrahydropyridine-3-(N,N-diethylcarboxamide).

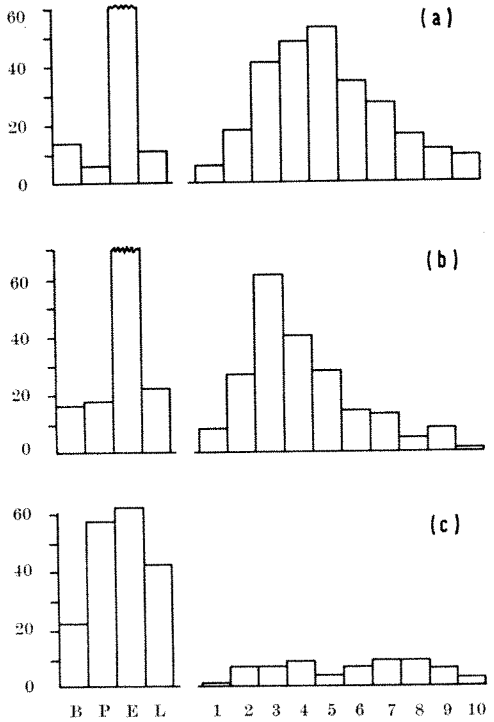

Fig. 2. The Bovet-Gatti profiles of the interaction between THPC and mescaline; (*a*) 15 mg/kg of THPC; (*b*) 12·5 mg/kg of mescaline; (*c*) the same, after treatment with 15 mg/kg of THPC. The latter is similar to the effect normally produced by 25 mg/kg of mescaline. The total number of responses in each category is given. B, Burst responses; P, premature responses; E, efficient responses; L, late responses; on the right the distribution of responses within the 10 s conditioned stimulus (CS) period is given. Hallucinogens increase B, P and L responses and shift the peak of the responses in the CS period to the left. The total number of E responses may be computed as the sum of the columns in the right-hand figure.

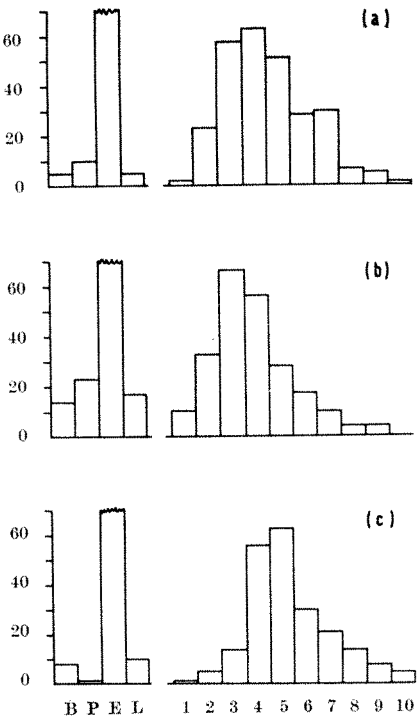

Fig. 3. The same for LSD: (*a*) saline; (*b*) 0·05 mg/kg of LSD; (*c*) 0·1 mg/kg of LSD after 15 mg/kg of THPC.

A second prediction of our hypothesis[5] is that blocking all three active groups on 5-HT (5-hydroxytryptamine) should inactivate the compound. 5-Methoxy-N,N-dimethyltryptamine is a most potent hallucinogen and disrupts rat behaviour at 2·5 mg/kg. We have tested the 1-methyl derivative of this drug and found it to have only a mild "stimulant" (amphetamine-like) profile at 10 mg/kg. This is in contrast to 1-methyl LSD which is an active hallucinogen.

We wished to know whether halving the LSD molecule and giving the bits separately would be effective. An approximation to this procedure can be carried out by determining whether 1-methyl-1,2,5,6-tetrahydropyridine-N,N-diethylcarboxamide (THPC; Fig. 1) potentiates the effect of mescaline. Fig. 2 shows that pre-treatment with 15 mg/kg of THPC, 45 min before treating with 12·5 mg/kg of mescaline, markedly potentiates the effects of the latter. This was confirmed in a second rat, the behaviour of which was completely disrupted for 30 min by the combination. When given before an equivalent dose of LSD (0·1 mg/kg), there was no such potentiation (Fig. 3), but the effect of LSD was inhibited. This dose of THPC by itself produced no behavioural effect (Figs. 2 and 3).

THPC could potentiate the effect of mescaline by one of two mechanisms: (i) if mescaline occupies only half the LSD site, as Snyder and Richelson have proposed[6], occupation of the other half by THPC might increase its effect, at the same time blocking binding of LSD, or (ii) THPC might affect some other brain mechanism, which, although it might have no direct behavioural effect, would nevertheless potentiate the effect of mescaline on some other system. But because mescaline and LSD are believed to act on the same mechanism, it is difficult to see why such a non-specific action should not potentiate the effect of LSD as well.

Correlation between Activity and Electronic State of Hallucinogenic Amphetamines

THE actions of hallucinogenic agents have been correlated with Hückel molecular orbital calculations of the π-electrons[1] and with fluorescent properties[2]. The Hückel correlations on three methoxylated amphetamines indicated that hallucinogenic activity correlated with energy of the highest occupied molecular orbital[1].

We calculated the total valence electron charge density, frontier electron density, dipole moment, total energy and all energy levels of thirteen hallucinogenic amphetamines using the INDO method (intermediate neglect of differential overlap)[3] which gives good results in the calculation of dipole moments, molecular geometries, electron nuclear hyperfine coupling constants and force constants[4-7]. Standard bond lengths and bond angles were used to generate cartesian coordinates, and vicinal methoxy groups were regarded as out of plane in a *trans*-configuration. All results were subjected to sequential multiple regression analysis.

Table 1 shows the correlation between hallucinogenic activities in man[8] and the energy of the highest occupied molecular orbital (E_H). For this correlation, the linear regression equation, $\log A = a + bx_1 + cx_2 \ldots$, may be expressed by the following equation, where A is hallucinogenic activity

$$\log A = 19{\cdot}07 + 35{\cdot}65\ E_H \qquad (1)$$

The equation for equimolar activity is

$$\log A = 18{\cdot}7 + 35{\cdot}1\ E_H \qquad (2)$$

For equation (1), $r = 0{\cdot}753$, $F = 14{\cdot}36$ and $P < 0{\cdot}005$; for equation (2), $r = 0{\cdot}756$, $F = 14{\cdot}62$ and $P < 0{\cdot}005$. This correlation suggests that the ease of perturbability of the π-electrons of the amphetamines is a determinant of hallucinogenic activity, the amphetamines presumably forming with the brain receptor a low energy, reversible π-molecular complex that gives rise to hallucinations.

Table 1. HALLUCINOGENIC ACTIVITIES OF AMPHETAMINE DERIVATIVES IN MAN AND ENERGY OF THE HIGHEST OCCUPIED MOLECULAR ORBITAL (E_H)

Derivative of amphetamine	Hallucinogenic activity	E_H (atomic units)
2,5-$(OCH_3)_2$-4-CH_3	80–100*	−0·4929
2,4,5-$(OCH_3)_3$	17	−0·5001
2,3,6-$(OCH_3)_3$	13	−0·5112
2,4,6-$(OCH_3)_3$	10	−0·5217
2,5-$(OCH_3)_2$	8	−0·5012
2,3,4,5-$(OCH_3)_4$	6	−0·5126
2,4-$(OCH_3)_2$	5	−0·5194
4-OCH_3	5	−0·5262
2,3,5-$(OCH_3)_3$ †	4	−0·5026
3,4,5-$(OCH_3)_3$	2	−0·5218
2,3,4-$(OCH_3)_3$	< 2	−0·5274
3,4-$(OCH_3)_2$	< 1	−0·5238
(Mescaline) ‡	1	−0·5226
(Amphetamine)	0	−0·5885

* The activity has been reported as 80 and 100[2,8].

† Limited number of tests.

‡ Mescaline, 3,4,5-trimethoxypherylethylamine, is not an amphetamine derivative but is used as a standard of hallucinogenic activity[8]. Amphetamine is not hallucinogenic and is not considered in the statistical analysis.

Table 2. E_H OF SOME UNTESTED AMPHETAMINE DERIVATIVES AND THEIR PREDICTED HALLUCINOGENIC ACTIVITIES

Derivative of amphetamine	E_H (atomic units)	Predicted activity
2,3,4,6-$(OCH_3)_4$	−0·5067	10·0
3,5-$(OCH_3)_2$	−0·5240	2·4
4-OH	−0·5296	1·5
3-OCH_3	−0·5316	1·3
2,6-$(OCH_3)_2$	−0·5334	1·1
2,3-$(OCH_3)_2$	−0·5346	1·0
2-OCH_3	−0·5371	0·9

Equation (1) was used for the predictions; equation (2) gives very similar results.

Although the correlation is significant ($r = 0{\cdot}753$, $F = 14{\cdot}36$, $P < 0{\cdot}005$), E_H does not account for the activities of all the compounds. The 2,3,6-trimethoxy and 2,4,6-trimethoxy derivatives and the 4-methoxy derivative are more active than expected if E_H is the only determinant of activity; and the 2,3,5-trimethoxy is less active. Other electronic or steric characteristics not revealed by this work could contribute to the activity. A better correlation cannot be expected. Drugs are involved in numerous interactions[9] before they induce hallucinations. Also, the error in measuring relative hallucinogenic activity in man is about 20 per cent (personal communication from A. T. Shulgin). Assuming that E_H is the only correlate of activity, we calculated the expected hallucinogenic activity of some untested amphetamines (Table 2). Of these, the 2,3,4,6-tetramethoxy derivative is the only one that should be significantly more potent than amphetamine. Shulgin states in a personal communication that the 2,3,4-trimethoxy derivative has measureable activity, but it is less than two[8]; our calculations predict that it has about the same activity as mescaline.

Rat Embryo Cells in Complement Fixation Tests for Murine Leukaemia Virus

HARTLEY *et al.*[1] have described a sensitive technique for the detection and quantitation of murine leukaemia viruses based on the development of complement fixing group specific antigen in infected mouse embryo (ME) tissue culture. This depends on the use of rat antisera in the complement fixation test to detect antigens shared by all known murine leukaemia viruses[2,3]. A number of tissue culture cells were tested for their ability to develop complement fixation antigen, and it was found that Swiss NIH-ME cells were the most sensitive host cells[1]. We have recently established and studied continuous lines of rat embryo (RE) cells—uninoculated and infected with Rauscher leukaemia virus (unpublished data of J. S. R. *et al.*)—and found that RE cells, as well as ME cells, can be used for the cultivation of Rauscher leukaemia virus. We now describe the use of RE cells in the test of Hartley *et al.*

The murine leukaemia and sarcoma virus strains used for this study had been serially passaged by Dr J. W. Hartley in NIH-ME cells and we passaged them several more times in the same type of culture before commencing our studies. Primary NIH-ME and Fisher RE cells were obtained from Microbiological Associates, or were prepared as previously described[1]. The growth medium was Eagle's minimal essential medium with 2 mM glutamine, 100 U penicillin and 100 µg streptomycin per ml.; and 10 per cent unheated foetal bovine serum; this was also used to maintain the cultures used for production of leukaemia virus, and for complement fixation antigen pools. Murine leukaemia viruses were assayed in secondary NIH-ME cultures by Hartley's test[1]. Complement fixation tests were carried out by the microtitre technique[4]. Titres were recorded as the reciprocal of the highest dilution giving 3+ to 4+ fixation of 1·8 units of complement. Rat antisera used in the complement fixation test were obtained from Fisher rats carrying transplanted sarcomas induced by Moloney sarcoma virus.

In the first experiment, 16 fluid ounce bottle cultures of secondary NIH-ME, RE and the eleventh passage of RE cells, were infected with 10^4 infectious units of Rauscher leukaemia virus; these cultures were harvested on the fourteenth day after inoculation. The media were removed and saved for infectivity assay, and the cells were packed for complement fixation antigens as previously described[5]. Table 1 indicates the ability of NIH-ME and RE cells and a continuous, normal cell line of RE cells (eleventh passage) to produce complement fixation antigen and yields of virus following inoculation with Rauscher leukaemia virus. A complement fixation titre of 1 : 32 was attained in NIH-ME and RE cells, while 1 : 8 was produced in the continuous RE cell line. Virus yields obtained in RE cells and the continuous RE cell cultures were higher than those in ME cells.

Table 1. PRODUCTION OF COMPLEMENT FIXING ANTIGENS AND YIELDS OF RAUSCHER LEUKAEMIA VIRUS IN RE (FISHER) AND ME (NIH SWISS) CELLS 14 DAYS AFTER INOCULATION

Cells	Antigen titre* against sarcoma virus : rat serum pool 6	Virus† yields
RE (secondary)	1 : 32	4·4
Serial RE (twelfth passage)	(8)	4·4
ME (secondary)	1 : 32	3·4

* Complement fixation titre = reciprocal of dilution giving 3+ to 4+ fixation of 1·8 units of complement (in parentheses indicates 2+).

† Complement fixing antigen induction titre ($\log_{10}$ TCD_{50}/ml.).

In the second experiment the sensitivity of NIH-ME and RE cells for the assay of Rauscher leukaemia virus was examined. The same stock of Rauscher leukaemia virus was titrated at the same time by the complement fixation antigen induction test[1], using two 60 mm plastic Petri dishes of secondary NIH-ME and RE cells for each ten-fold dilution. The results (Table 2) demonstrate that the endpoint titres of Rauscher leukaemia virus were the same in ME and RE cells.

Table 2. COMPARATIVE TITRATION OF RAUSCHER LEUKAEMIA VIRUS IN RE (FISHER) AND ME (NIH SWISS) CELLS 20 DAYS AFTER INOCULATION

Cells	Virus dilution	Sarcoma virus : rat serum pool 6 (1 : 4)	Infectivity titre (Log_{10} TCD_{50}/0·4 ml.)
RE	10^{-1}	4	$10^{-3\cdot0}$
	10^{-2}	4	
	10^{-3}	4	
	10^{-4}	0	
	10^{-5}	0	
ME	10^{-1}	4	$10^{-3\cdot0}$
	10^{-2}	4	
	10^{-3}	3	
	10^{-4}	0	
	10^{-5}	0	

Additional experiments were designed to examine the comparative sensitivity of rat strains for complement fixation antigen production of Rauscher leukaemia virus. Different strains of rat were obtained from Microbiological Associates, and primary cultures of rat embryo were prepared as described. Table 3 shows the results of comparative sensitivity of rat strains for complement fixation antigen production of Rauscher leukaemia virus. All the RE cells derived from different strains yielded comparable complement fixation antigens with NIH-ME cells, the highest titre being that for the "OM" rat strain. No positive complement fixation reactions were found in cell pack preparations of the normal, uninoculated RE cells.

		+	(16)
		−	0

* See Table 1; 0 = 0/4.

NIH-ME and RE cells were further tested for comparative sensitivity in their ability to produce complement fixation antigen of various established murine leukaemia and sarcoma virus strains. Various stock viruses were inoculated into ME and RE cells at the same time, and harvested on the same day. Complement fixation antigen titres in RE cells were in almost all instances as high as, or higher than, those obtained in NIH-ME cells (Table 4).

Our results indicate that RE cells seem to be useful for the propagation and assay of murine leukaemia and sarcoma viruses cultured *in vitro*. Complement fixing antigen titres and yields of virus produced in rat embryo cells are similar to those obtained in NIH-ME cells, the most sensitive host cell system so far reported[1]. RE cells provide an additional system for use in Hartley's test, and may have advantages for the isolation of certain viruses. We hope to study the comparative sensitivity of RE cells for virus yields of various murine leukaemia viruses and for the isolation of viruses from field specimens of leukaemia. Ting[6] observed that Moloney sarcoma virus induced morphological transformation of rat embryo cells *in vitro*, and infectious viruses were found in the culture media of the transformed culture. Continuous viral replication and malignant cell transformation by

Serological Studies with EB Virus in Infectious Lymphocytosis

RECENT epidemiological studies reveal a highly significant correlation between infectious mononucleosis and the development of serum antibodies to EB virus (EBV)[1,2]. It has been suggested that these findings indicate that EBV is probably the causative agent in infectious mononucleosis. An alternative hypothesis is that EBV may merely be a poorly immunogenic, non-aetiological "passenger" virus that is activated non-specifically during the proliferation of lymphoreticular cells in infectious mononucleosis with subsequent appearance of detectable EBV antibodies[3–8]. The second hypothesis may be tested in part by studying EBV antibody responses that occur in infectious lymphocytosis, a mild communicable paediatric illness of unknown aetiology in which elevated absolute and relative lymphocyte counts develop, usually without specific signs or symptoms[9].

An outbreak of infectious lymphocytosis occurred in 1960 at Junior Village, the receiving home for the Washington, DC, Department of Welfare. (This community consists of homeless but otherwise normal children.) At the time of this outbreak, the infectious disease experience of Junior Village children was under continuous longitudinal surveillance[10] and serial serum specimens were routinely collected from all children and stored at −20° C. During the summer and early autumn of 1960 infectious lymphocytosis was detected in twenty-two children.

Acute and convalescent sera from ten of the children were studied for antibodies to EBV as well as to cytomegalovirus (CMV) and herpes simplex virus (HSV), all herpes group viruses. CMV has been implicated in mononucleosis syndromes[11] and antibody to CMV was therefore studied. HSV testing was included as a control herpes group virus. The indirect immunofluorescence test for detection of EBV antibody was used[12] using the Jiyoye Burkitt tumour cell line as antigen. Controls were included to rule out staining by immunoglobulin G producing cells. The complement fixation test for CMV and HSV was used as described elsewhere[13]. None of the children developed a four-fold or greater antibody rise to EBV or CMV, although the lymphocytosis was impressive in each instance (Table 1).

* Numbers in parentheses indicate percentage lymphocytes.

† Titres expressed as reciprocal of serum dilution.

‡ Serum anti-complementary.

§ Positive control serum included in test.

Thus, according to serological testing, EBV and CMV are not associated with the pathogenesis of infectious lymphocytosis. Further, the failure to find an EBV antibody rise in any of the children indicates that EBV, if present in trace amounts in three children, did not become activated during the striking proliferation of their lymphocytes. This may have implications in the interpretation of the role of EBV in infectious mononucleosis.

Programmed Synthesis and Export of Immunoglobulin by Synchronized Myeloma Cells

THE mammalian cell life cycle is determined by a series of coordinated events which reflect time-dependent gene expression, although the duration of some of these events appears to be flexible[1]. Examples of both cyclic[2] and steady state[3] activities of certain enzymes in different, synchronized mammalian cell lines have been reported; there is at least one known example[3] of enzyme inducibility that is restricted to part of the cell cycle. Collagen, a protein synthesized in large amounts for export, is produced throughout the life cycles of several fibroblast lines at rates corresponding to those of overall protein synthesis[4].

The chronology of immunoglobulin production by cultured lymphoid cells is of special interest. Immunoglobulins are readily identifiable proteins secreted in large quantities, and control of their synthesis is of central importance in the immune response. Although there is the possibility that regulation of immunoglobulin synthesis in myelomas may be different from that in normal cells, cultured myeloma cells provide a useful model for analysing the regulation of immunoglobulin synthesis, particularly because they produce a homogeneous protein.

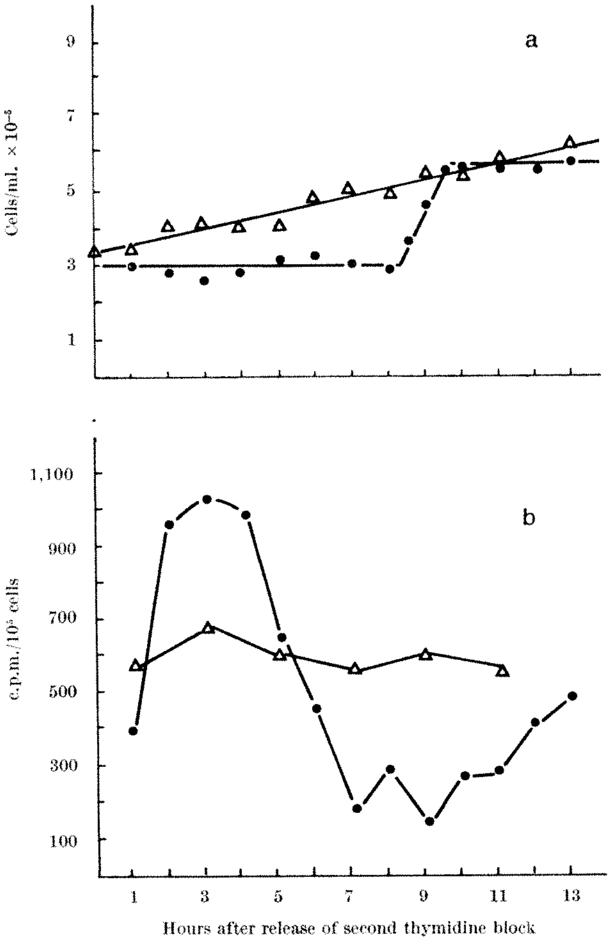

Fig. 1. *a*, Cell counts in synchronized and asynchronous cultures of C1 myeloma cells. Cell numbers were counted at hourly intervals after the removal of the second thymidine block. ●, Thymidine treated cells; △, randomly growing control cells. *b*, Thymidine uptake into DNA of synchronized and asynchronous cultures. ^{3}H-thymidine (0·04 μCi/ml.) was added at hourly intervals, for 1 h pulses, to a series of 5 ml. aliquots of C1 myeloma cells after the release of the second thymidine block. At the end of the pulse time, cells were collected on 'Millipore' filters, washed with Hanks solution and then DNA was precipitated with 5 per cent trichloroacetic acid. The filters were dried and counted in a liquid scintillation spectrometer using toluene phosphor. Control asynchronous cell cultures were treated as above, but were pulsed for 1 h periods every second hour. ●, Thymidine treated cells; △, randomly growing control cells.

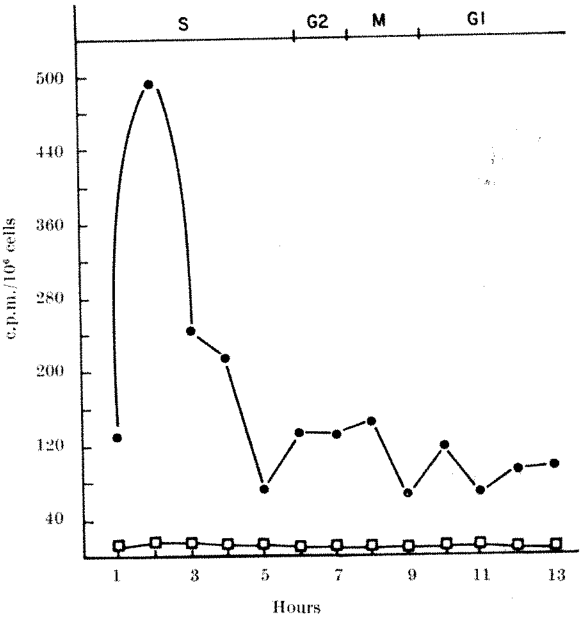

Fig. 2. Pulse-labelling of γG_{2a} in synchronized cultures of C1 cells. Beginning immediately after the release of the second thymidine block, a series of 10 ml. aliquots of cells were pulse-labelled for 1 h, at hourly intervals, with a mixture of ^{3}H or ^{14}C-labelled amino-acids (0·5 μCi/ml. each of glutamic acid, aspartic acid, proline, valine and glycine). Soluble cell extracts were prepared as follows. Cells were harvested by centrifugation and culture medium was removed. The pellet was washed three times with Hanks solution, lyophilized, then dissolved in water. The suspension was centrifuged at 100,000*g* for 60 min, the supernate removed, lyophilized and then taken up in a known volume of 0·05 M barbital, *p*H 8·6. The culture medium was dialysed against distilled water for 48 h and centrifuged at 12,000*g* for 10 min to remove insoluble euglobulins. The supernatant was removed and $(NH_4)_2SO_4$ added to 45 per cent saturation. The precipitate was collected by centrifugation, dissolved in water, dialysed against distilled water, lyophilized, then taken up in a known volume of barbital buffer. All samples were assayed for labelled γG_{2a} by co-precipitation[8] with unlabelled γG_{2a} myeloma protein, using goat anti-γG_{2a} antiserum (kindly provided by Dr B. W. Papermaster). Precipitates were collected on 'Millipore' filters and counted as described in the legend to Fig. 1. In this and following figures, the time of labelling is given in hours after release of the second thymidine block (which was designated as the beginning of S phase). ●, Cell extracts; □, culture media.

Many myeloma cell lines are now available in continuous culture[5]. One such line, C1, derived from the C3H mouse plasmacytoma X5563, synthesizes a γG_{2a} immunoglobulin[6]; a derived negative mutant, XC1, is also available. These two cell lines have different chromosome numbers[7] and the C1 cell line carries a virus-like particle not visible in XC1 (ref. 5). We have examined the synthesis and secretion of γG_{2a} immunoglobulin by C1 cells synchronized in suspension culture by double thymidine block. Both synthesis and export of γG_{2a} are time-ordered events, reaching maximal rates during restricted portions of the cell life cycle.

C1 and XC1 cell lines were established in continuous suspension culture in a modified Eagle's medium from initial cultures provided by Drs M. Cohn and K. Horibata (Salk Institute, San Diego). The most effective conditions for establishing synchronous growth were as follows: cells were subcultured in fresh medium at 2×10^5 cells/ml., grown for 16 h with 10^{-3} M thymidine, 7 h in the absence of thymidine and a further 16 h with 10^{-3} M thymidine. After removal of the second thymidine block, the extent of synchrony was assessed by serial cell counts and measurement of ^{3}H-thymidine incorporation into DNA (Fig. 1). Control asynchronous cells had a doubling time of 16 to 18 h. In thymidine treated cultures, S phase occupied 6–7 h, G2 phase 1·5–2 h, M phase 1·5–2 h and G1 phase about 3–4 h, giving a total generation time slightly less than that of asynchronous cultures. Approximately 90 per cent synchrony was obtained by this procedure.

In radiolabelling experiments, synchronized cultures were incubated with radioactive amino-acids for the required time and radiolabelled γG_{2a} was assayed in soluble cell extracts and in the medium by co-precipitation[8]. In pulse-labelling experiments, radioactive amino-acid incorporation into γG_{2a} was measurable at all times during the cell life cycle but was clearly maximal early in S phase (Fig. 2), reflecting time-dependent regulation of γG_{2a} biosynthesis. The basal level of synthesis was rather higher than could be accounted for by a random distribution in time of S phase-limited synthesis of γG_{2a} in the small proportion of asynchronous cells present. Little or no labelled γG_{2a} appeared in the medium in a 1 h pulse time (Fig. 2), so that the amount of radiolabel appearing in intracellular γG_{2a} during 1 h does reflect net synthesis of immunoglobulin in this period.

In continuous labelling experiments, in which radioactive amino-acids were added following removal of the second thymidine block and hourly samples assayed thereafter, the rate of incorporation of label into cellular γG_{2a} was non-linear, being maximal early in S phase (Fig. 3*a*). Label was not limiting, for the incorporation into total cell protein was linear for at least 9 h. A similar initial slope for incorporation of isotope into γG_{2a} was obtained by plotting cumulative counts of samples sequentially pulse-labelled in S phase. The rate of appearance of labelled γG_{2a} in the medium was also non-linear, with an initial lag followed by an increasing rate of export of newly synthesized immunoglobulin which reached a maximum in G2 and M phases (Fig. 3*b*). There was thus a dissociation in time between maximal synthesis and maximal secretion of γG_{2a}, the intervening lag period being of the order of hours rather than minutes.

Total γG_{2a} (labelled and unlabelled) was determined by immunodiffusion assay. Intracellular γG_{2a} rose to an apparent steady state concentration in mid S phase, which was maintained until G2 and then decreased (Fig. 3*c*). The rate of accumulation of γG_{2a} in the medium increased after an initial lag (Fig. 3*d*). In other experiments, the accumulation of intracellular γG_{2a} was also calculated from radiolabelling data, by plotting labelled γG_{2a} as a percentage of total (soluble and insoluble) labelled cellular protein measured at hourly intervals. Here the intracellular concentration of newly synthesized γG_{2a} was non-linear and reached a maximum in late S phase, intermediate in time between the periods of maximal synthesis and maximal export. In contrast to the cyclic synthesis of γG_{2a}, the synthesis of total cellular protein was approximately linear until mitosis. Intracellular labelled γG_{2a} reached a maximum of 1·5–2 per cent of total labelled cellular protein in synchronized cells.

We conclude, first, that both biosynthesis and export of γG_{2a} immunoglobulin by C1 myeloma cells have cyclic maxima, which occur during different, restricted portions of the cell life cycle and are separated by an intervening period of intracellular accumulation (Fig. 4). These findings indicate that both synthesis and export follow a programme determined in some way by the timing of other events in the cell life cycle. Second, the non-steady state synthesis of immunoglobulin contrasts with the above-mentioned pattern of collagen synthesis in fibroblasts[4]. Despite the species difference, it is of interest

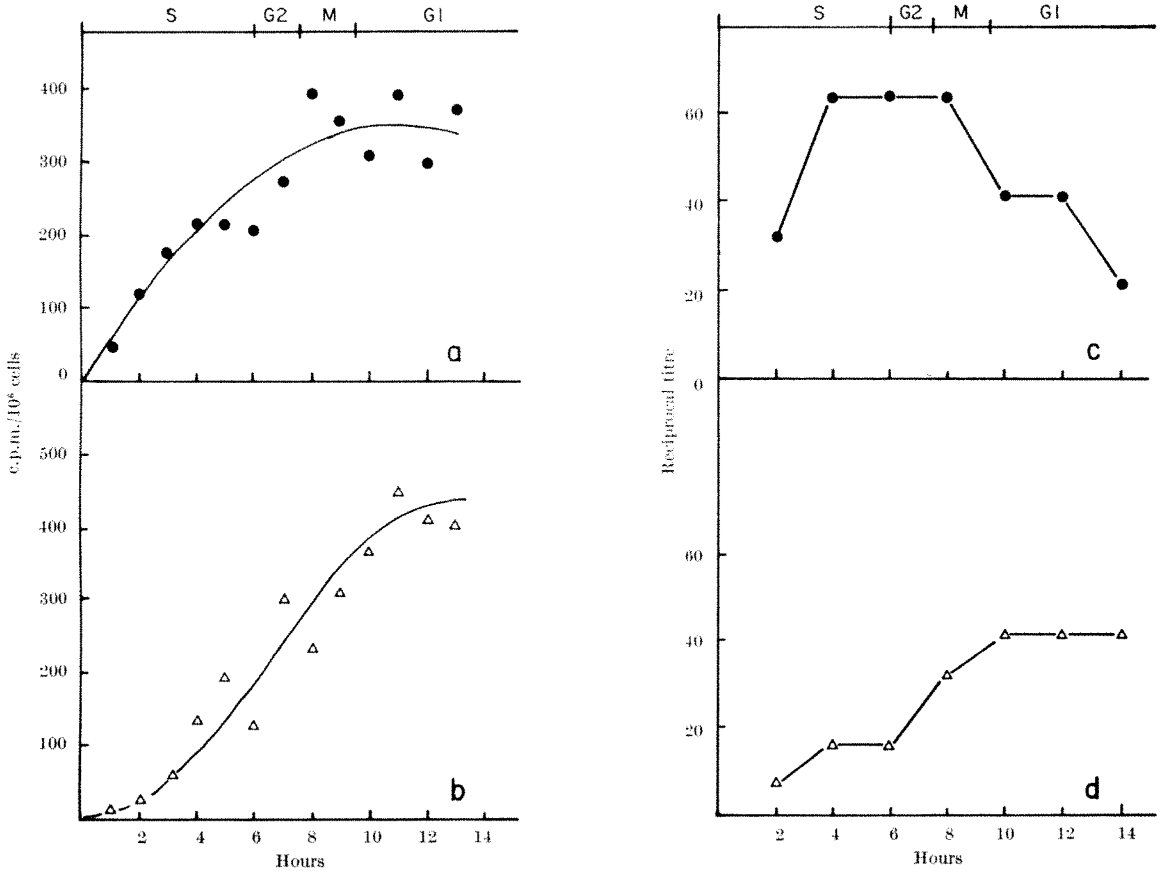

Fig. 3. *a* and *b*, Continuous labelling of γG_{2a} in synchronized cultures of C1 cells. Radioactive amino-acids (0·2 μCi/ml. each of glutamic acid, aspartic acid, proline, valine and glycine) were added to the cultures immediately after removal of the second thymidine block and samples taken at hourly intervals thereafter. Cell extracts and medium were prepared and assayed as described in the legend to Fig. 2. ●, Cell extracts; △, culture media. *c* and *d*, Determination of total γG_{2a} in cell extracts and culture media of synchronized cultures of C1 myeloma cells by immunodiffusion. Cell extracts and media were processed as described in the legend to Fig. 2. Serial, doubling dilutions of each sample were made; 5 μl. of each placed in the outer wells of Ouchterlony slides and 5 μl. of anti-γG_{2a} (diluted 1/5) placed in the centre well. Diffusion was carried out at 4° C for 48 h; the slides were then washed in barbital buffer for 24 h and stained with thiazine red. The γG_{2a} titre was taken as the greatest dilution giving a clearly visible band. The discrepancy between γG_{2a} content of cells and media in the 12–14 h period is evidently because of the limitations of the technique. ●, Cell extracts; △, culture media.

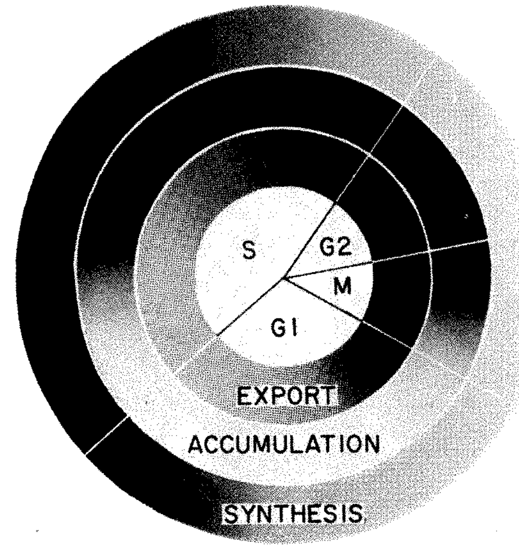

Fig. 4. Schematic representation of synthesis, intracellular accumulation and export of γG_{2a} as a function of time during the life cycle of C1 myeloma cells. The γG_{2a} concentration is proportional to the density of the shading within each zone.

to compare the present data for a mouse myeloma with those reported recently for two human lymphoid cell lines[9]. In the latter case, maximal synthesis, as judged by immunofluorescent staining, was observed in late G1 and early S phases; this was followed closely, however, by maximal export in contrast to the situation in the myeloma. Third, it can be inferred that in C1 myeloma cells—and apparently in the human lymphoid cells—immunoglobulin biosynthesis is inducible, possibly by an intrinsically generated inducer. Alternatively, by analogy with tyrosine aminotransferase induction in synchronized hepatoma cells[3], periodically permitted operation of an extrinsic inducer present in the medium could be responsible. The negative mutant, XC1, is attractive from the viewpoint of further examination of the induction process, but so far we have failed to induce γG_{2a} synthesis in this mutant (unpublished data).

Two questions can now be posed. First, does the periodicity of γG_{2a} synthesis reflect a restricted period of transcription of the corresponding messenger RNAs late in G1 phase ? If so, the kinetics of γG_{2a} synthesis might simply reflect the survival–decay curves of these messenger RNAs. Second, what governs the kinetics of export ? On the basis of current knowledge, the most likely factor is addition of the carbohydrate moiety of the immunoglobulin[10,11]. Possibly one or more relevant enzymes are also subject to cyclic induction in relation to the phase of cell life cycle. These two possibilities can be tested experimentally.

Histones and Gene Control

HISTONES are thought to control the transcription of DNA in some way. There are five main fractions in the nuclei of mammalian, bird, fish and plant somatic cells: F1 and F2B, lysine-rich histones; F2A1 and F3, arginine-rich histones; and F2A2, an intermediate type[1].

Allfrey, Littau and Mirsky[2] and Hindley[3] have concluded that the arginine-rich histones are the best repressors of DNA template activity, whereas Barr and Butler[4] and Huang, Bonner and Murray[5] reported that the lysine-rich histones were the most efficient. We now show how these differences can be reconciled, and question the currently accepted view that the histones must be removed from the DNA before transcription can occur.

Histone fractions vary considerably in their ability to precipitate a given quantity of DNA[6]. F1, the lysine-rich histone, will precipitate all the DNA at a ratio of histone to DNA of about 0·8 to 1·0, whereas F3 requires a ratio of about 1·5 to 1·0 for complete precipitation. More recent work[7] has shown that in the correct conditions further additions of histone cause the precipitated DNA–histone complex to redissolve. Does the DNA–histone complex become available again as a template for RNA synthesis, as it redissolves, even though it contains more histone ? Fig. 1 shows that it does.

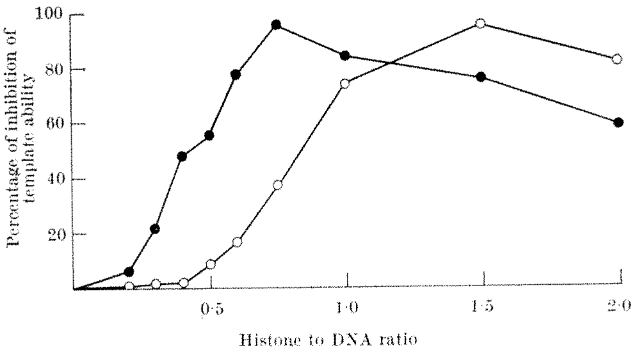

Fig. 1. The inhibition by histone fractions of the ability of DNA to act as a template for RNA synthesis *in vitro*. ●, Lysine-rich histone F1; ○, arginine-rich histone F3. Histones F1 and F3 were prepared according to Johns[8], method 2. DNA was prepared by the method of Kay, Simmons and Dounce[9]. RNA polymerase was prepared by a modification of the procedure of Chamberlin and Berg[10] and used at the stage designated fraction 3. To assay for RNA synthesis at the various histone to DNA ratios, varying amounts of the F1 and F3 fractions in a constant volume (50 μl.) of 0·14 M NaCl were added to aliquots (50 μl.) of DNA solution (2 mg/ml.) in 0·14 M NaCl to give histone to DNA ratios varying from zero to 2 : 1. The assay reagent mixture was then added: 0·05 M Tris-HCl buffer *p*H 7·8 (0·5 ml.) containing 4 μmoles $MgCl_2$; 1 μmole $MnCl_2$; 1 μmole β mercaptoethanol; 200 nmoles each of ATP, CTP, GTP, UTP and 0·55 nmoles ^{14}C-ATP (specific activity, 89 mCi/mmole). The reaction was started by adding RNA polymerase (10 μl. containing 300 μg protein). After incubation at 37° C for 10 min the reaction was stopped by adding 3 ml. of 0·5 M perchloric acid and the precipitate was collected on Whatman 'GF/C' filters, washed with 15 ml. 0·5 M perchloric acid and 10 ml. ethanol and dried. The filters were counted in 10 ml. toluene-based phosphor in a Packard liquid scintillation counter. Controls were as shown in Table 1. The figures given are averages of five experiments. All assays were carried out in duplicate.

The ratios of histone to DNA for complete precipitation using F1 and F3 are 0·8 and 1·5 to 1·0 respectively. Fig. 1 shows that at these ratios there is virtually complete inhibition of RNA synthesis. This is not surprising, for it is unlikely that the precipitated DNA can act as a template. Further additions of histone cause the complex to become more soluble and to direct RNA synthesis once more. The discrepancies between the results of the various authors can be reconciled if the ratios of histone to DNA used in their experiments are taken into account. When DNA is precipitated with an equal amount of various histones, the ratio histone to DNA being 1·0 (Huang, Bonner and Murray[5] and Barr and Butler[4]), or at any ratio less than 1·0 (see Fig. 1), F1 is the best repressor. At the higher histone to DNA ratios (Hindley[3]), F3 is the best repressor. The ratio of histone to DNA used in the experi-

Table 1. INCORPORATION OF ^{14}C-AMP INTO PERCHLORIC ACID PRECIPITATE

	pmoles ^{14}C-AMP incorporated
Complete reaction mixture (no histone, 100 μg DNA)	7,800

Complete reaction mixture + ribonuclease	200
Reaction mixture less enzyme	Zero
Reaction mixture less DNA	400

ments of Allfrey *et al.*[2] is difficult to assess because histone was added directly to nuclei. In these conditions the histones would be well in excess of the DNA and the arginine-rich histone F3 seems to be the best repressor.

We suggest that up to the point of complete precipitation of DNA by added histones the curves of inhibition of template activity (Fig. 1) and the curves of precipitation of DNA by histone[6] are so similar that the assay for template ability is simply a very sophisticated method for measuring DNA precipitation. The increase in template ability when the precipitate is redissolved by more histone raises a number of interesting questions.

Is the restriction of template ability by histones as measured *in vitro* simply a measure of the inability of the reagents to penetrate and react with the aggregated complex? Is it necessary to remove the histones from the DNA–histone complex to increase the template ability of the DNA, or is it only necessary to render the whole complex more soluble or more accessible to reagents? Is it possible that *in vivo* RNA synthesis is controlled in this manner?

There is no evidence at present which indicates that the histones must be removed from the DNA before it can be used as a template for the *in vivo* synthesis of RNA. There is good evidence, however, that in the active regions of Drosophila salivary glands[11], and in the active diffuse chromatin of interphase lymphocytes[12], there is an increase in the acidic protein content of the region; but a decrease in the content of histone relative to the DNA has never been demonstrated.

It is possible that specific acidic proteins[13] combine with the required portion of the genome to render it more accessible to the RNA synthesizing system. A possible mechanism for this, involving the steric hindrance of the RNA polymerase by the DNA supercoil, has been discussed recently[14].

Changes in the Amount of DNA in Cell Nuclei during Vertebrate Evolution

THE pronounced differences in the DNA content of cell nuclei of vertebrates have recently been discussed[1-3], but these articles did not mention the possible correlations between the evolution of nuclear DNA with the evolution of cell size which was simultaneously reviewed[4]. I now suggest that these two evolutionary phenomena are closely linked and result from common causes.

Many authors have observed a nearly perfect correlation between the size of the nucleus and the amount of DNA[5-9]. Others have denied the existence of such regularity or have insisted that there are exceptions[10-13], emphasizing that the nuclei are not only composed of DNA, and that the variations in the amount of remaining components as induced, for example, by starvation or by different stages of secretory cycle, cause changes in the nuclear size without affecting the amount of DNA. This being so, a perfect linear relationship between these two values cannot be expected. Nevertheless, it is obvious that the DNA is a very important component of the nucleus and that the differences in its amount are strongly reflected in the size of the nucleus. Fankhauser[14], for example, has demonstrated that the polyploid amphibian nuclei can invariably be recognized by their size.

The correlations between the nucleus and the cell are generally recognized[15-17]. Recently, Uzzell[18] used the size of the erythrocyte for the recognition of polyploids in the *Ambystoma jeffersonianum* complex. *Amphiuma*, which has the largest amount of DNA in its nuclei, also has the largest cells. The nucleocytoplasmic ratio may, of course, fluctuate[19], but it is true to say that when homologous cells in a similar functional state are compared the nucleocytoplasmic ratio is usually found to be uniform.

When the ratio of the nuclear volume to cell volume is calculated in cells of different size, it is usually found that in the larger cells the ratio is shifted toward the nucleus[20] (not toward the cytoplasm as I have erroneously stated[4]); that is to say, big cells have nuclei that are proportionally larger.

The next step of the reasoning, namely, the premise that the size of the cell has adaptive value and has been accordingly influenced by natural selection, is probably the most controversial and needs more verification from observations and experiment. In a recent article[4], I concluded that large cells probably have the metabolic rate limited by the surface to volume ratio. In those vertebrate groups which have increased their metabolism during evolution, the cell size has correspondingly decreased. Large cells are, however, more economic than small ones, so that in every instance when the metabolic level decreased, there was a tendency toward an increase in cell size. Godula[21] has compared the amount of some organelles in the liver cell of *Xenopus laevis* and *Ambystoma mexicanum* with that reported for the rat liver cells, and has found that, although the liver cell of *Xenopus* is about 40 per cent larger and that of *Ambystoma* about five times larger than the rat liver cell, the total number of mitochondria in one cell is 1,060 in the rat, 242 in *Xenopus* and 899 in *Ambystoma*. He also noted that the mitochondria in *Ambystoma* seem to have a smaller number of cristae than those of *Xenopus*. Goniakowska (in preparation) has found that the largest erythrocytes investigated (of axolotl) consume the smallest amount of O_2 per mg of cell volume, whereas the smallest erythrocytes (of *Hyla*) consume the largest amount of O_2 per mg of cell volume. There is therefore some reason to assume that the cell size may have an adaptive value. The adaptive values of variations in the amount of DNA are, however, much less convincing. The hypothesis that the redundancy of genetic information resulting from the increase in the amount of DNA may confer some insurance against mutagenic agents[4] disagrees with the findings of Sparrow, Schairer and Sparrow[8], who have demonstrated that the radiosensitivity of plant cells is directly proportional to the DNA content and to the volume of the nucleus. It could be supposed that the animals with large amounts of DNA per nucleus can produce more proteins; this was, however, not confirmed by Comings and Berger[22]. These findings also do not support the hypothesis[2] that the redundant DNA allows a slow accumulation of genome variability which may later be brought into play during a period of evolutionary explosion and diversification. Instead, it seems that natural selection acts chiefly on the size of the cell, although the correlated change in the amount of nuclear DNA may be the initial modifier of the genotype.

The following account of the changes in the amount of DNA in vertebrate nuclei is proposed. The invasion of estuaries and later of fresh water by the ancestors of vertebrates induced an increase in the cell size, accompanied by an increase in DNA. The tendency in vertebrate evolution turned later towards an increase in metabolic rate. Among aquatic vertebrates this trend is most pronounced in the teleosts. The decrease in cell size resulted in a decrease in the amount of DNA. The invasion of land by early tetrapods was probably accompanied by a decrease in metabolism and an increase in the size of the cells.

Only later was there a trend toward an increase in metabolism. Morescalchi[23] thinks that the evolution of anurans was accompanied by a reduction in the number of chromosomes. The erythrocytes of the primitive *Sphenodon punctatus* are larger than erythrocytes of all present day reptiles[24]. Birds have the highest metabolism accompanied by the smallest cell size and by the smallest amount of DNA per nucleus.

The development by Dipnoi of a resistance to high concentrations of urea in the blood was paralleled by an increase in the size of the cell and in the amount of DNA per nucleus. There is probably a similar reason for the very high amount of DNA in nuclei of Urodela, although the largest cells are found in such animals as *Amphiuma* and *Rhyacotriton*[25] which are not known to accumulate urea, but in *Scaphiopus* the amount of DNA in the nucleus is very low[1], though this toad can accumulate urea to a considerable extent[26].

In attempting an explanation of this, one comes against the problem that not enough is known about the factors that influence the size of the cell and the amount of nuclear DNA. It has been observed[9] in plants, for example, that there is a correlation between the amount of DNA in the genome and in the duration of mitotic cycle, and this also seems to be the case in some animals. According to Astaurov[27], the rate of mitosis in triploid and tetraploid silkworms is decreased in inverse proportion to the increase in the number of chromosomes and the size of the cell. Dettlaff[28] has calculated that at a temperature of about 18° C the duration of the mitotic cycle during the early stages of segmentation is 105 min in *Ambystoma*, 90 min in *Triturus*, 60 min in *Rana* and 50·3 min in *Acipenser*. This value is 31 min in *Misgurnus*[29]. These data seem to agree with the assumption that the duration of the mitotic cycle during the development of fishes and amphibians is influenced by the amount of nuclear DNA. Such correlation, however, is absent in birds and mammals. The strong selection pressure for the shortening of embryonal development, which in *Scaphiopus* takes place in temporary pools, is therefore the probable reason for the small amount of DNA in this genus.

I conclude that the differences in the amount of nuclear DNA in vertebrates are a result of differences in the cell size. Changes in the cell size during evolution have resulted from adaptations to various environments and to different modes of life. Big cells and a large amount of DNA per cell are correlated with a low level of metabolism and with the ability of cells to tolerate considerable variations in the composition of body fluids. Small cells and a small amount of DNA in the nucleus characterize groups with a high metabolism and with a precise regulation of their internal environment.

Evidence for Epitaxy in the Formation of Collagen and Apatite

A NUMBER of structural relationships between the organic and inorganic components of bone are known from X-ray diffraction and electron microscopy studies. The interrelationships have led to a theory of mineralization involving the process of epitaxy, that is, the orientated overgrowth of bone mineral on certain well crystallized areas of the organic matrix. This differs in principle from theories of mineralization which assign no active role to the organic matrix in the mineralization process. Epitaxy clearly requires some structural symmetry, but considerable mismatch seems to be permissible in the process of crystal seeding. Results reported here indicate a structural symmetry in collagen and apatite in the presence of copper ion and support the concept of epitaxial growth; areas of identical crystal order on apatite and the organic substrate have been demonstrated as would be expected if epitaxy were a relevant mechanism.

In the technique used, the essentially diamagnetic substances to be studied are labelled with an inorganic paramagnetic ion. The ion is detected by electron paramagnetic resonance (EPR), and from an analysis of the shape of the signal the crystal field symmetry, if any, at the ion site is inferred. The cupric ion, Cu(II), was chosen as the labelling ion because (*a*) it has a known affinity for the substrates studied[1], (*b*) its hyperfine lines are sensitive to the local crystal fields[2], and (*c*) there have been previous studies involving Cu(II) bound to a variety of substrates which provide a basis for comparison with the present results[3–7].

Clinically normal human tendon was obtained during surgery and stored in an air-dried state until studied. Bovine tendon and animal skin gelatine were purchased. Human bone mineral was extracted by refluxing whole cortical bone pieces approximately $2 \times 3 \times 5$ mm in ethylenediamine for 72 h, then washing for 24 h in distilled deionized water at room temperature. Bone collagen was prepared by treating pieces of cortical bone with either 1·0 M formic or 1·0 M HCl for 72 h.

Bone mineral was exposed intact (that is, as the same crystalline aggregate as the original sample of refluxed bone) to solutions containing known concentrations of Cu(II). The ratio of the weight of solid to volume of solution was about 500 mg/l., and the standard exposure time for all materials was 24 h. The samples were rinsed, air-dried and reduced to powder. Human and bovine tendons and bone collagen were minced with scissors to a length of about 1 mm. After treatment with Cu(II) at a solid to solution ratio of 200 mg/l., they were rinsed and dried in the same way as the mineral. Cu-gelatine films were prepared by evaporating to dryness 5 per cent gelatine solutions made 0·068–0·83 mM with respect to Cu(II).

The native materials not treated with Cu(II) solutions exhibited either no resonances[1] or weak lines at $g = 2{\cdot}0$ which did not interfere with the present analysis[8–10].

After immersion in solutions containing Cu(II), bone mineral exhibited a well defined Cu(II) EPR spectrum (Fig. 1*a*). For solutions in the range 0·034 mM to 0·350 mM with respect to Cu(II) the spectrum is sharp and distinct and the overall line shape remains constant. As the molarity is raised above 0·35 mM the low field lines are less resolved and the main absorption peak becomes featureless. These results do not depend on the anion. Equimolar solutions of the sulphate, nitrate and chloride of Cu(II) yield identical spectra. Cupric ions absorbed on collagenous structures from solutions in the range 0·008 to 0·080 mM yield an EPR spectrum similar to that of copper labelled bone mineral (Fig. 1*b*). The set of four constants of the spin Hamiltonian which characterize each resonance are, within experimental error, identical for the two materials; thus the results indicate that there are sites of the same symmetry on each material. To give some idea of the spread in the spin Hamiltonian constants describing absorbed Cu(II), some representative values from the literature are given in Table 1. The virtual identity of the constants for bone mineral and collagen as compared with the spread in values shown in Table 1 is what is meant by "sites of the same symmetry" on collagen and bone mineral.

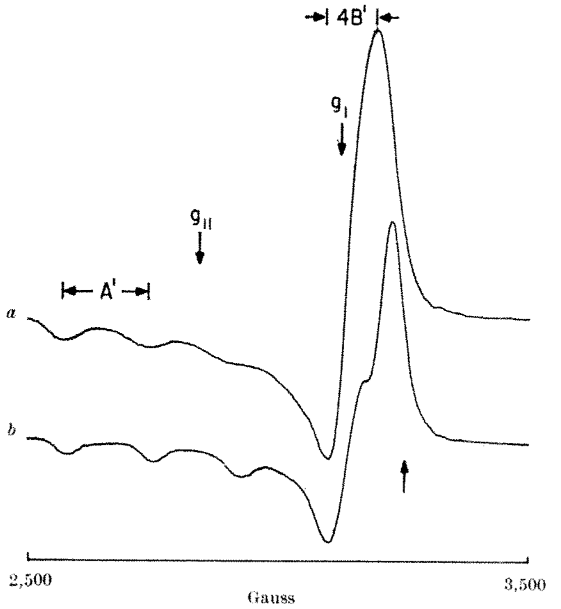

Fig. 1. EPR spectrum from (*a*) bone mineral, (*b*) tendon collagen after treatment with cupric ion. The arrow denotes the position of $g = 2{\cdot}00$.

We find no difference between the various collagen structures and gelatine with respect to the short range order about artificially added copper sites (Table 1). This seems to indicate that the secondary protein structure is not an important factor in determining the site crystal field symmetry.

Relationship between Mitosis and the Ordered Structure of the Stratum Corneum in Mouse Epidermis

THE cells of the stratum corneum of mammalian skin, although usually regarded as being randomly arranged, have been shown to be aligned in regular columns[1]. This arrangement was suggested to result from a regular pattern of cell migration from the basal layer. The available evidence, however, links cell migration to cell division and suggests that cell division is a random process[2].

The method previously used to display the columnar structure involved the expansion of the stratum corneum with a solution of sodium hydroxide during which the deeper layers of the epithelium were destroyed[3]. It has been found that acid solutions are as effective as sodium hydroxide for expansion of the stratum corneum, but they cause less damage to the deeper strata, and furthermore the damage caused by either agent is greatly reduced by a brief period of fixation before expansion. This has made possible a study of the position of mitosis in relation to the structure of the stratum corneum, and preliminary results suggest that there is a functional arrangement of the cells of the basal layer corresponding to the overlying columns.

We used the epidermis of the mouse because it consists of very few cell layers and has a particularly precise

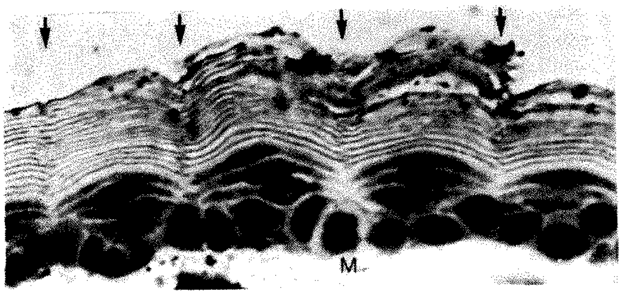

Fig. 1. 5 μm cryostat section of mouse ear epidermis after expansion in 0·1 M NaOH to display the junctions of the columns of squames in the stratum corneum (arrowed). The position of the mitotic figure (M) can still be identified. Alcohol fixed, stained 0·1 per cent methylene blue.

columnar arrangement of squames. Adult male mice were treated with 'Colcemid' (Ciba), 0·2 mg/100 g body weight for 6 h, to arrest dividing cells at metaphase. Cryostat sections, 5 μm thick, were fixed for 5 min in 70 per cent alcohol and treated either by staining in 0·1 per cent methylene blue followed by expansion in 0·1 M NaOH, or by expansion in 0·1 per cent methylene blue acidified to *p*H 4 with HCl. On 346 photographs of mitosis (Fig. 1) printed at a standard magnification, the outline of the individual squames of the columns in the stratum corneum could be seen clearly. The position of mitosis in relation to the columns was obtained by considering the basal region beneath each column to be divided into four regions of equal size. Mitoses occurring in either of the two outer quarters were classified as those related to the squamous junctions, and those occurring in the inner quarters related to the central region of the columns. The midpoint of the interdigitation of the lowest squames was used to define the position of the junctions between the columns, and the centre of each mitotic figure was classified as lying beneath an inner or outer quarter depending on the ratio m/s (Fig. 2).

If cell division occurs randomly among basal cells, it is to be expected that a similar number of mitotic figures would be seen in inner and outer quarters, for these represent equal lengths of the basal layer. We found 193 mitoses in the outer quarters and 153 in the inner quarters. The χ^2 test applied to these figures gave $P < 0\cdot05$, which suggests that mitosis has a tendency to occur beneath the junctional region of the overlying squames.

The columns of squames of the epidermis of the mouse ear, when viewed from the intact surface, are irregularly hexagonal with a diameter of about 30 μm. Sections 5 μm thick cut at right angles to the surface of such material pass through the central region of some columns but only through the peripheral region of others, and this is reflected in the width of the cut surface of each column seen in the sections. A width was chosen which divided the columns into two groups of approximately equal numbers, group 1 with a wide cut surface, and group 2 with a short cut surface. On the hypothesis that there is a tendency for mitosis to occur in the junctional region, the central area beneath each column should contain fewer mitoses. It is then to be expected that the group 1 sections will include this central region and show a greater tendency for mitosis to occur in outer quarters, and that group 2 which pass through the junctional region only would have an essentially random arrangement. We found that there was a greater tendency for mitosis to occur in the outer quarters of group 1 ($P < 0\cdot01$) and that there was no significant difference between the inner and outer quarters of group 2. This supports the hypothesis that mitotic activity is occurring principally beneath the periphery of each overlying column.

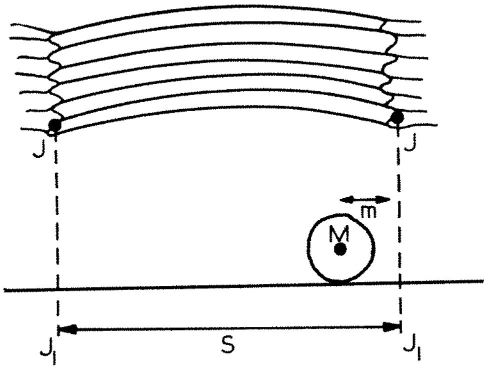

Fig. 2. Diagram of the method for determining the position of a mitotic figure in relation to the overlying structure. J, Midpoints of interdigitation between adjacent columns. Lines JJ_1, drawn through points J perpendicular to the line connecting them, define the basal region lying beneath the column of squames. S, Width of cut surface of column; m, distance of the centre of the mitotic figure (M) from the nearest junction.

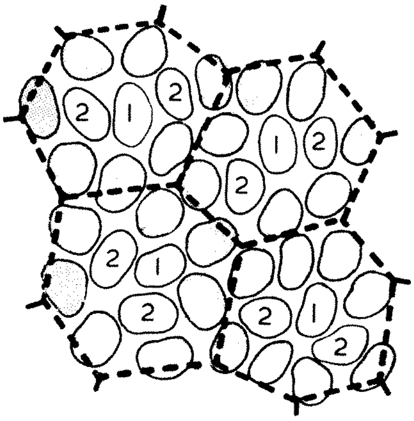

Fig. 3. A hypothetical pattern of basal-cell behaviour. Unit groups of basal cells lie beneath each polygonal column of squames. The rings of mitotically active cells (stippled) lying beneath the squamous junctions (broken line) produce differentiating cells (2) which move centrally to migrate into the stratum spinosum from the centre of each group (1).

If the columnar arrangement of squames of the stratum corneum results from some physical or cell-contact property during cell flattening, the regular stacking of the postmitotic differentiating cells of the stratum spinosum (Fig. 1) could result in a variation of chalone concentration in the basal layer. This would produce areas of relatively high and low mitotic activity (W. S. Bullough, personal communication). On the other hand, regular stacking could result from an intrinsic pattern of basal cell behaviour. Taken together with the finding that emigration from the basal layer is restricted to the oldest G_1 cells in the vicinity of mitosis[4], our results suggest that basal cells can be grouped into functional units, in which cells with mitotic potential lie in a ring at the periphery of each unit and produce differentiating cells which pass centrally to migrate into the stratum spinosum from a position beneath the centre of each overlying column (Fig. 3).

Table 1. DISTRIBUTION OF MITOTIC FIGURES

	Sections cut through		
	Central area	Edge of column	Total
Outer quarters	108	85	193
Inner quarters	71	82	153
χ^2	$P < 0\cdot01$	N·S	$P < 0\cdot05$

The presence in the basal layer of functionally separate unit groups of cells may prove to be a natural feature of the physiology of certain epithelia. It would imply a level of organization exhibiting finer spatial control than has previously been described in this tissue and would be important to an understanding of the control of epithelial growth both in normal and abnormal states.

I thank Professor A. E. W. Miles and Dr M. K. S. Hathorn for advice. This work was supported by a grant from the Medical Research Council.

Nuclear Pockets and Projections in Fish Melanoma

NUCLEAR pockets (blebs or loops) and nuclear projections have recently been reported in various lymphoid cells of healthy[1,2] and leukaemic[3,4] human subjects, in Burkitt tumour lymphoblasts[5] and in thymocytes[6,7]. They have also been observed in myeloid cells of amphibians[8] and in lymphoid cells of birds and cyclostomes[9].

We report here the observation of similar nuclear structures in melanotic melanomas and amelanotic albino melanomas of platyfish-swordtail hybrids. The melanomas were fixed in glutaraldehyde, postfixed in osmium tetroxide and embedded in 'Epon 812'. Thin sections stained with lead citrate were examined in a Philips 'EM 300' electron microscope.

Ultrastructural examination of the melanomas revealed that among small, highly dendritic melanocytes there are some large melanosome-containing cells possessing highly polymorphic nuclei (Fig. 1). Most of these nuclei show one or more nuclear pockets (Fig. 2) and/or projections (Fig. 3). The nuclear pockets are formed of a thin sheet of chromatin bounded on both sides by the nuclear envelope. They resemble those observed by other investigators in various lymphoid cells[1-9]. Frequently the cytoplasm surrounded by the chromatin sheet contains various organelles—for example, melanosomes (Fig. 2), endoplasmic reticulum or mitochondria (not illustrated). The nuclear projections are usually composed of a thin envelope-bounded sheet of chromatin with a dilation at its end (Fig. 3). The nuclear projections themselves often contain nuclear pockets (as indicated by arrows in Fig. 3). Frequently two nuclear projections can be seen meeting one another (Fig. 4), thus supporting the scheme for pocket formation postulated by Törö and Oláh[6] and later by Sebuwufu[7].

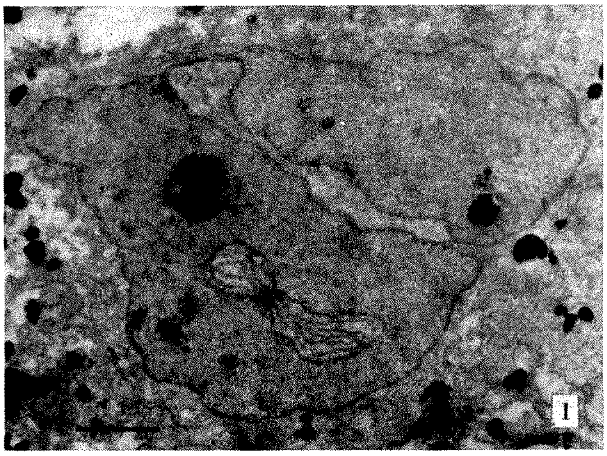

Fig. 1. Polymorphic nucleus in a melanotic melanoma cell. The nucleus contains a cytoplasmic area filled with rough endoplasmic reticulum.

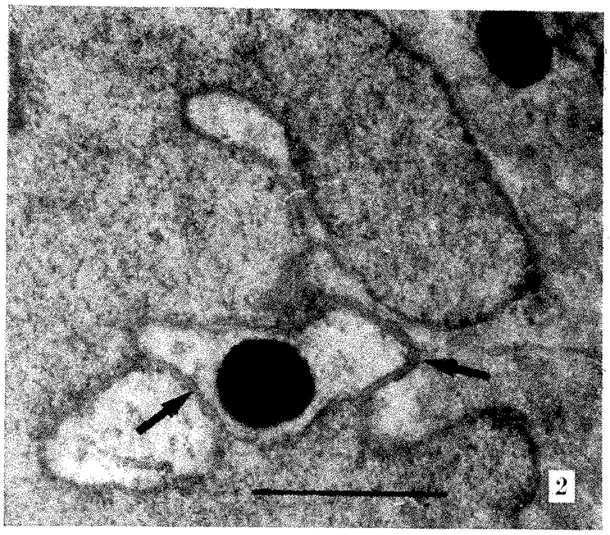

Fig. 2. Nuclear pockets in a melanotic melanoma cell. Arrows point to envelope-limited sheets of chromatin which surround a melanosome.

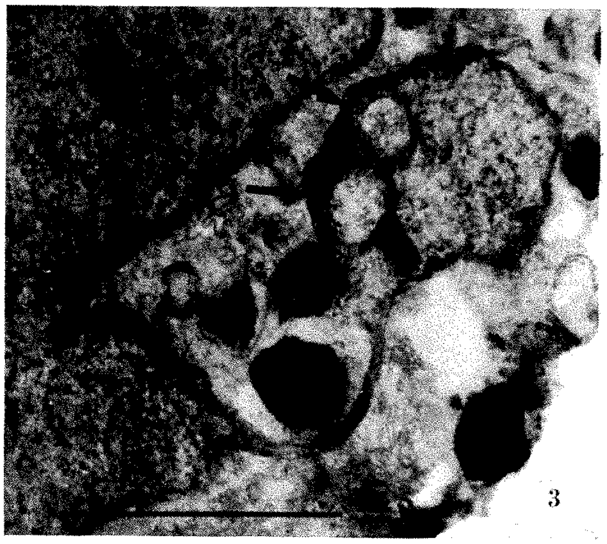

Fig. 3. Nuclear projection in a melanotic melanoma cell. Arrows indicate nuclear pockets.

Occasionally we have observed nuclei in melanoma cells containing large envelope-bounded cytoplasmic areas (Fig. 1) which represent deep indentations or perhaps wider nuclear pockets in another cross-section. The cytoplasm inside the nucleus is usually filled with several structures—for example, rough endoplasmic reticulum (Fig. 1), myelin figures, or phagocyte-like vacuoles which degrade melanosomes, or premelanosomes, in the case of albino melanomas. The latter structures have been found to be characteristic of melanocytes in platyfish-swordtail melanomas[10].

We can give no satisfying interpretation of the existence of nuclear pockets and projections. Their occurrence in melanoma cells and, as recently reported, in tumoral epithelial and connective tissue cells[11] and in follicle cells[12] may indicate that these structures are not only characteristic of cells of the vascular system but are more widely distributed. We conclude from our electron microscopic studies that nuclear pockets and projections do not occur in the small dendritic melanocytes, the nuclei of which are ovoid or round in shape. This finding suggests that in large cells nuclear pockets and projections, as well as highly polymorphic nuclei, may have the function of

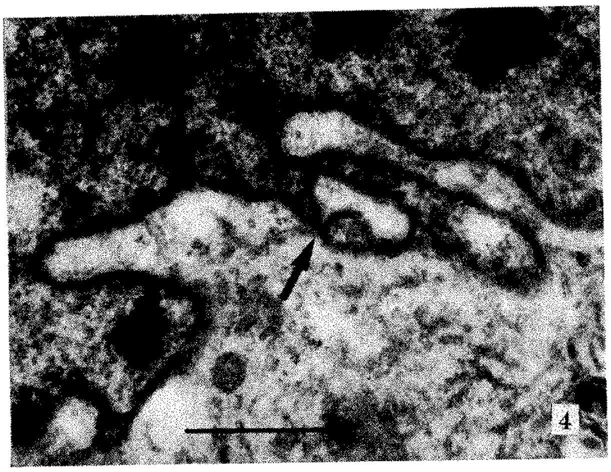

Fig. 4. Nuclear projections in an amelanotic albino melanoma cell. Arrow indicates where the projections seem to undergo pocket formation.

increasing the area of chromatin in contact with the cytoplasm (see refs. 2 and 9).

Unique Vascular Relationship in the Human Umbilical Cord

THE reactivity of both perfused and isolated segments of human umbilical vessels to various pharmacological agents has already been reported[1-5]. Without exception, serotonin (5-hydroxytryptamine) has been found to be a potent constricting agent of both umbilical artery and vein. In perfusion studies, however, arteries and vein were generally not perfused simultaneously or, in cases where they were, drugs were administered only to the arterial perfusing fluid.

We have perfused both the arteries and the vein simultaneously in 10 cm segments of human umbilical cords, and injected drugs into both the arterial and venous perfusing fluids, which consisted of Krebs–Henseleit solution, equilibrated with oxygen: carbon dioxide (95 per cent : 5 per cent), in physiological pressures (10 mm of Hg in the vein, 55 mm of Hg in the arteries), although the flows obtained (12 ml./min in the vein, 6 ml./min in each artery) were considerably less than those found *in utero*[6]. Decreased flow is a familiar problem in studies of isolated perfused placentae and umbilical cords[2]. Perfusion pressure was measured in the vein using a Statham pressure transducer. Spirally and longitudinally cut strips of umbilical artery and vein were examined in a tissue bath, and the muscular activity was recorded isotonically on a kymograph.

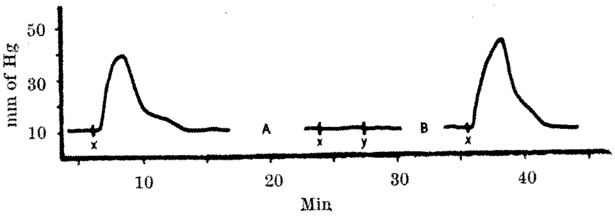

Fig. 1. Pressure changes from serotonin in perfused umbilical vein before and after insertion of a stainless steel rod into one artery. Serotonin was injected as a bolus at x (10^{-8} g) and at y (10^{-7} g). The rod was inserted during interval *A*. Note that changes in perfusion pressure could not be obtained with serotonin while the rod was in place. Removal of the rod (in interval *B*) was followed by a return of the response to intravenous serotonin.

Very small doses (2×10^{-9} to 1×10^{-8} g) of serotonin injected as a bolus in the venous perfusing fluid caused increases in venous perfusion pressure while the arteries were present in the segment of cord, whether or not the arteries were perfused. Administration of as much as 10^{-5} g of serotonin to the arterial perfusing fluid did not alter venous perfusion pressure, although arterial flow was terminated rapidly. When the arteries were dissected sharply from thirty segments their response to intravenous serotonin was abolished. This response was also abolished in twenty cords when a stainless steel rod was inserted through one of their arteries, thus uncoiling the vessels from around the vein. When the rod was removed the system recorded its sensitivity to serotonin, which indicates that the contractile mechanism involved was undamaged by the procedure (Fig. 1).

We then investigated whether removal of the arteries from the segment of cord had damaged the contractile mechanisms of the vein. Spirally and longitudinally cut strips of umbilical vein were prepared from unperfused segments of the cord, from segments perfused with the arteries in place, and from segments perfused after removal of the arteries. In every case, the venous strips prepared from these three kinds of tissue had identical sensitivity to serotonin in the tissue bath, each contracting at a threshold dose of serotonin of 10^{-9} g/ml.

Longitudinally cut strips of human umbilical artery contracted in response to serotonin, with a threshold concentration of 1 to 5×10^{-9} g/ml., representing a unique component of human arterial tissue. We suggest that the contraction of the longitudinal muscle fibres in the arteries, which coil around the vein in the human umbilical cord, was responsible for the increase in venous perfusion pressure after addition of serotonin to the venous perfusing fluid. That this may be a unique mechanism in man, or at least in the higher primates, is suggested by the observation that sheep umbilical cords contain two arteries and two veins with little coiling of one about the other, and the apparent absence of functional longitudinal muscle in either vessel[7].

Fitting Sine Curves to 24 h Urinary Data

In studies of biological rhythms it is often desirable to obtain an objective estimate of the phase and amplitude of a suspected rhythm from observation recorded over a single cycle, such as a single period of 24 h. The usual technique is to attempt to fit the observations to a sine curve. Most techniques of fitting a sine curve are applicable only to a series of points and, for conventional methods, the points must be uniformly spaced in time. Many biological data, especially of renal excretion but also of respiratory or heat exchange, represent the average value of the variables since the previous sampling. The sampling intervals are often irregular and are correctly represented graphically by a histogram, though in published work they are often presented as points at the midpoint of the collection period. This does not cause much distortion if the time intervals are short and equal, but a gross distortion of the actual behaviour is introduced when, for example, there are long collection periods of urine as in a night's sleep.

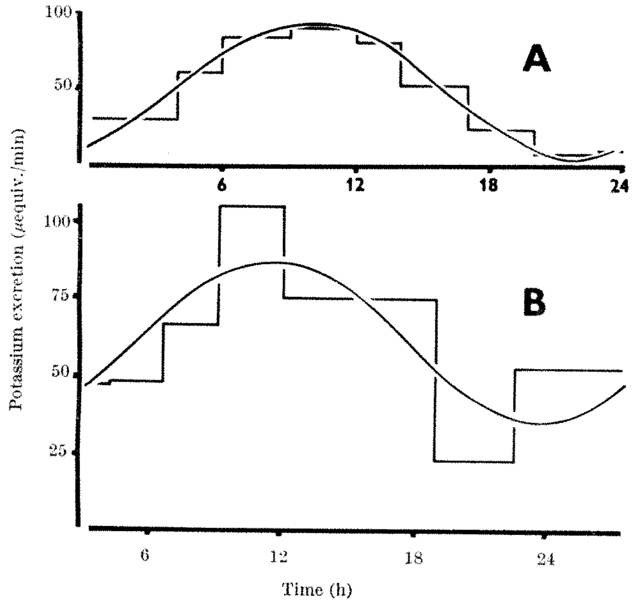

Fig. 1. Rate of potassium excretion measured in a series of urine samples over 24 h. and the sine curve which best fits the data. *A*, Artificially constructed to illustrate perfect fit. *B*, Experimental data, with best fitting sine curve calculated by computer.

We have attempted to fit sine curves to such data in three ways. The first method, which makes hand calculation feasible, was to calculate the excretion rate corresponding to each 2 h period over 24 h and fit a sine curve to the twelve equally spaced mid-points thus derived[1,2]. More recently we have used a computer program, hereafter referred to as method *A*, which fitted a sine curve to a large number of equally spaced points. Each urine sample was treated as if it were a series of identical consecutive samples, each covering the longest time interval that was an integral fraction of every sampling period. For example, if every sample was produced exactly on a quarter-hour, the whole 24 h would be treated as ninety-six successive samples, a sleep of 7·5 h being then regarded as thirty identical samples.

Both these treatments, even if approximately correct in their predictions, involve some falsification of the experimental evidence. The production of thirty identical successive urine samples would be evidence against a sinusoidal oscillation. The following considerations suggest a more satisfactory approach.

If the abscissa of a histogram is time, and the ordinate is the rate of excretion of a urinary constituent, the area beneath each rectangle of which the histogram is composed represents the amount excreted, such as a volume of urine or milliequivalents of an electrolyte. In the fitted sine curve this amount is represented by the integral of the sine curve over the appropriate time interval, and the fit of the curve is indicated by the accuracy of prediction of this area. It is thus theoretically possible, even if infinitely improbable, to obtain a perfect fit, as in the artificially constructed example in Fig. 1*A*. The criterion here adopted to assess departure from perfect fit is to take the differences between predicted and observed areas, square them and sum the squares, and we have written a computer program, referred to as method *B*, which calculates the parameters of the sine curve of period 24 h that will reduce this sum of squared deviations to a minimum, consistent with an initial condition that the mean rate of excretion, and consequently the total excretion over the 24 h as predicted from the sine curve, must be equal to the observed value.

Fig. 1*B* shows an example of this procedure applied to experimental data of rate of potassium excretion sampled over 24 h. Because this process of calculating the deviation from a sine curve bears some formal similarity to the measurement of variance, we have adopted a similar statistical procedure:

$$a = \frac{\text{sum of squared deviation from the curve}}{n-3}$$

$$b = \frac{\text{sum of squared deviations from mean}}{n-1}$$

$$Q = a/b, \text{ where deviations are of area}$$

The sum of squared deviations of determined areas from those predicted from the sine curve is divided by the number of urine samples minus three, because three parameters are needed to define a sine curve. This quantity is a measure of goodness of fit, and is then divided into a quantity bearing a similar formal resemblance to a total variance, namely, the sum of squared differences between determined areas and those predicted from uniform urinary excretion over the whole 24 h, divided by the number of urine samples minus one. The ratio thus obtained, while not strictly a variance ratio, conveys similar information about the goodness of fit of the sine curve.

This method may be made clearer by Fig. 2 and Table 1, in which the same experimental data for potassium excretion are plotted with the sine curves fitted by methods *A* and *B*. In Fig. 2*A* the deviations from the mean excretion over 24 h are shaded, and their numerical value and the sum of their squares are shown in Table 1. In Fig. 2*B*, the deviations from the sine curve are similarly shaded and their numerical values and sum of squares, together with those derived from method *A*, are also shown in the table. It will be seen that for sample 3 the deviation is very small, for it consists of nearly equal positive and negative portions. The table further shows that both sine curves give a much better prediction of potassium excretion than does the 24 h mean, and that method *B* is better than method *A*.

The program could readily be modified to be applicable to data covering an integral number of cycles, or with more difficulty to a non-integral number. With a much greater expenditure of computer time it could be extended to test the fit to a series of periods, as is sometimes required in "free-running" experiments, and thus to search for some outstanding frequency in a long series of "noisy" data. It could also be extended to fitting periodic curves containing higher harmonics.

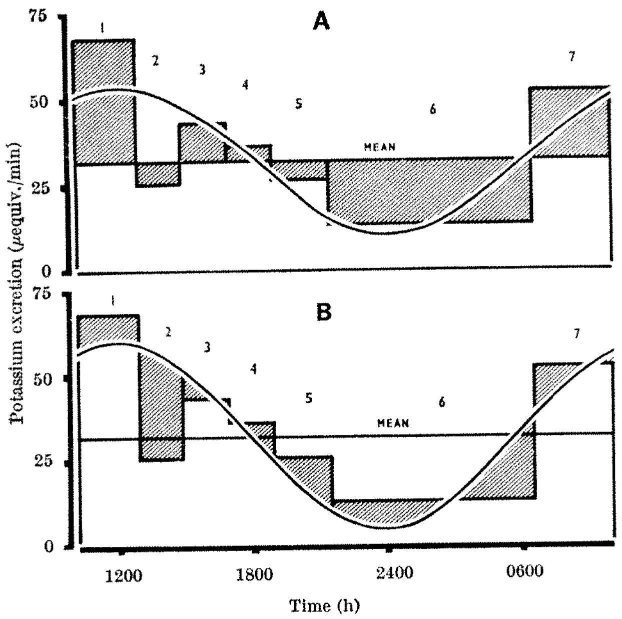

Fig. 2. Potassium excretion over 24 h observed experimentally, with best fitting sine curves calculated by methods *A* and *B*. Shaded areas represent, in milliequivalents of potassium, the deviation of observed potassium excretion in each urine sample from *A*, mean excretion rate over 24 h, and *B*, excretion predicted from the sine curve.

Table 1. CALCULATION OF DEVIATIONS IN FIG. 2

Urine sample	K^+ content (milli-equivalents)	Deviation from mean 24 h rate (milli-equivalents)	Deviation from sine curve *A* (milli-equivalents)	Deviation from sine curve *B* (milli-equivalents)
1	10·478	+5·593	+2·351	+1·424
2	3·060	−0·712	−3·026	−3·498
3	5·184	+1·402	−0·038	−0·152
4	4·320	+0·538	+0·349	+0·624
5	3·870	−0·857	+0·707	+1·477
6	7·160	−10·330	−2·136	−0·496
7	11·308	+4·375	+1·791	+0·622
$s[d^2]$		160·628	23·077	17·491
Degrees of freedom		6	4	4
Variance		26·771	5·769	4·373
Variance ratio			4·640	6·122

The idea behind method *B* arose out of a discussion with Professor J. F. Adams, and we thank Dr A. V. Reader for assistance with the computer program.

Stimulation of Glycerol Production in Fat Cells by Cholera Toxin

CELL-FREE filtrates of cultures of *V. cholerae* contain a toxin which produces fluid accumulation in ligated rabbit ileal loops[1] and increases capillary permeability in rabbit skin[2]. In isolated rabbit ileal mucosa, it induces chloride secretion and inhibition of normal, non-glucose mediated sodium absorption[3]. The effects on ion fluxes are similar to those produced by theophylline or cyclic adenosine 3′,5′-monophosphate (cAMP) and, in addition, the effects of cholera toxin on gut fluid loss are mimicked by agents that can increase tissue cyclic AMP levels[4]. We therefore investigated the effects of the toxin on fat cells in which accumulation of cAMP resulting either from increased synthesis (for example, with epinephrine) or from decreased degradation (for example, with theophylline) results in stimulation of lipolysis[5]. As reported below, cholera toxin increases glycerol production by fat cells. These studies have provided the basis for a simple, sensitive assay for choleragen.

Table 1. INHIBITION OF THE TOXIN EFFECT ON GLYCEROL PRODUCTION

Exp. No.	Conditions	Toxin μg/ml.	Percentage inhibition of toxin effect Hour 2	Percentage inhibition of toxin effect Hour 3
1	Plus cyclic 3′,5′-AMP, 1 mM	40	55	30
2	Plus ethacrynic acid, 1 mM	96	100	100
	3 mM		100	100
	1 mM	240	100	100
	3 mM		100	100
3	Minus Ca^{2+}	40		84
	Minus Mg^{2+}			48
	Minus Ca^{2+} and Mg^{2+}			91
4	Minus K^+	200	59	71
	Minus Ca^{2+} and Mg^{2+}		69	68
	Minus Ca^{2+}, Mg^{2+} and K^+		91	94

In exps. 1 and 2, cells were washed and incubated in Krebs–Ringer phosphate medium with additions as indicated. In exp. 3, cells were washed in medium from which Ca^{2+} and Mg^{2+} were omitted and incubated in this medium with and without the addition of Ca^{2+} and/or Mg^{2+} at final concentrations equal to those in the complete medium. Exp. 4 was carried out in a similar fashion except that Ca^{2+}, Mg^{2+} and K^+ were omitted from the medium used for washing and added to the incubation medium where indicated. Samples (0·5 ml.) of cells plus medium were taken after 0, 1, 2 and 3 h of incubation for determination of glycerol. Percentage inhibition of the toxin effect during the second and third hours of incubation was calculated from the mean glycerol production during these periods for two or three incubations under each set of conditions.

Procedures for the preparation and incubation of fat cells and for the determination of glycerol are described in an earlier publication from this laboratory[6]. Krebs–Ringer phosphate medium containing bovine serum albumin, 30 mg/ml., was used for all incubations and for washing cells except where indicated (that is, Table 1, experiments 3 and 4). Each incubation contained 15–40 mg fat cells in a total volume of 2·5 ml. Lyophilized supernatant fluid from cultures of *V. cholerae* Ogawa B 1307 (Wyeth Co.) grown according to Craig[7] was used except where noted. Activity is expressed in terms of dry weight of the lyophilized material.

A significant increase in glycerol release could be demonstrated after 3 h incubation with 8×10^{-6} g/ml. of the Wyeth crude toxin. Even with high concentrations of toxin (4×10^{-4} g/ml.) there was no stimulation of lipolysis during the first hour of incubation. After the first hour the rate of lipolysis increased progressively. Fig. 1 illustrates the time course of the reaction. This experiment was terminated at 3 h. In other experiments the rate of lipolysis continued to increase during the fourth hour. This was demonstrable, however, only when incubations were carried out with small amounts of cells and/or with low concentrations of toxin, for accumulation of free fatty acid beyond about 6 moles per mole of albumin inhibits lipolysis[8]. Thus, in the experiment summarized in Fig. 2, the rate of glycerol production during the third hour was greater than that during the second hour with concentrations of toxin below 1×10^{-4} g/ml., but above this level was no longer proportional to toxin concentration. During the second hour the rate of glycerol production was proportional to toxin concentration over the entire range tested.

As shown in Fig. 1, the addition at the end of the second hour of either prostaglandin E_1 or insulin at concentrations that inhibit hormone stimulated lipolysis[5,9] inhibited the effect of toxin during the subsequent hour. Cyclic AMP inhibits theophylline stimulated lipolysis in Krebs–Ringer phosphate medium[10] and likewise interfered with the effect of toxin (experiment 1, Table 1). Ethacrynic acid reduces gut fluid loss and the ion flux alterations produced by cholera toxin[11]. At concentrations of 1 or 3 mM, it completely inhibited the effect of toxin on fat cells (experiment 2, Table 1). In the same experiment, 1 mM ethacrynic acid inhibited the lipolytic effect of 2×10^{-8} g/ml. epinephrine to a lesser extent and only during the second 30 min of incubation. (The incubations with epinephrine were terminated at 60 min.) The effects of epinephrine and other lipolytic hormones are influenced by the ionic composition of the incubation medium. In experiment 3, Table 1, omission of either Ca^{2+} or Mg^{2+} significantly decreased the effect of 4×10^{-5} g/ml. of toxin. Omission of both divalent cations nearly abolished it. In experiment 4, Table 1, the effect of 2×10^{-4} g/ml. was decreased about 70 per cent in medium without Ca^{2+} and Mg^{2+}. The omission of K^+ similarly decreased the effect of toxin. In the absence of all three ions, that is, in all Na^+ medium, there was virtually no effect of toxin.

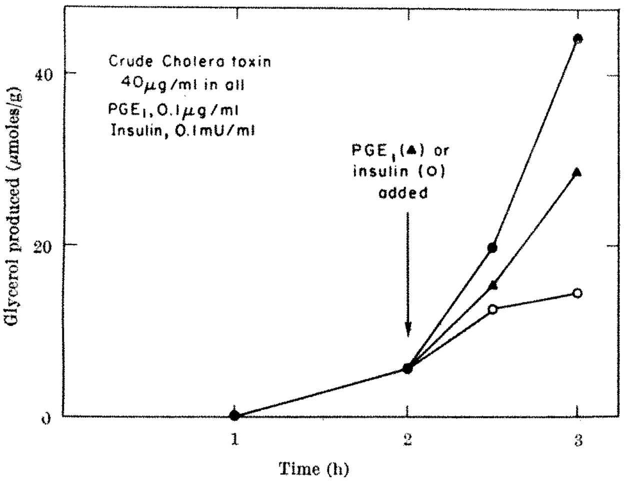

Fig. 1. Effect of crude cholera toxin on glycerol production. Crude cholera toxin was present throughout the incubation period. ●, Glycerol produced in the presence of toxin alone. Glycerol production in the absence of toxin (or with boiled toxin, 200 μg/ml.) was less than 5 μmoles/g/3 h (not shown). Points represent the mean of duplicate incubations that agreed within < 5 per cent.

Because the toxin preparations used in initial experiments were a mixture of many products of *V. cholerae*, it was necessary to ascertain whether the lipolytic response was due to the fluid transport active principle (choleragen) which causes fluid loss in gut. Boiling for 5 min inactivated the choleragenic toxin and also inactivated the lipolytic agent. Neither was dialysable through 'Cellophane' membranes. Concentrated cell-free filtrate from a strain of *V. cholerae* (strain In 569B) grown in conditions such that it did not produce detectable choleragen also had no effect on lipolysis. A highly purified choleragen[12], kindly provided by Dr Richard A. Finkelstein, significantly stimulated lipolysis at a concentration of $3{\cdot}5 \times 10^{-9}$ g/ml. A very similar but biologically inactive form of this toxin (choleragenoid) produced no lipolysis at 1×10^{-4} g/ml. Both of these materials produced a single band in polyacrilamide gel electrophoresis and elicited a single precipitin band when reacted with antisera which had been adsorbed with live *V. cholerae*[12]. The sensitivity of fat cells to cholera toxin is similar to that of skin and considerably greater than that of rabbit ileal loops. Antisera prepared against purified toxin abolished the lipolytic activity of choleragen.

The results of all our experiments thus far are consonant with the conclusion that it is the fluid transport active factor (choleragen) that stimulates lipolysis in fat cells. This, together with the fact that the stimulation of lipolysis is proportional to log-dose over a wide range of toxin concentrations, has made it possible to use the fat cell system as a rapid, sensitive assay for choleragen and cholera antitoxin (our unpublished experiments). The fat cell system, consisting as it does of a homogeneous population of free floating cells, may prove useful in investigation of the mechanism of action of choleragen which is still to be elucidated. The findings presented here, as well as the data from studies of effects of cholera toxin on the intestine[3,4], are consistent with the idea that choleragen may affect processes mediated by cAMP in tissues outside the gastrointestinal tract.

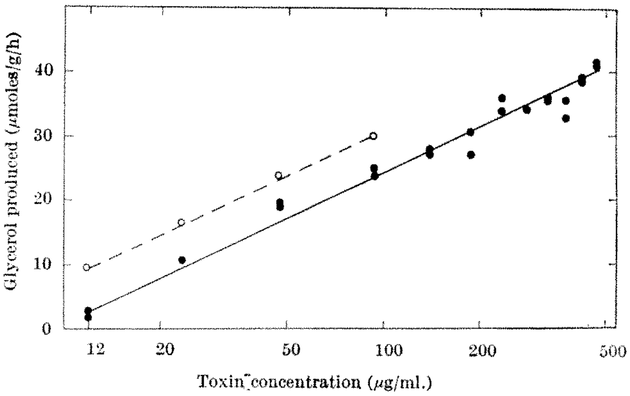

Fig. 2. Glycerol production as a function of concentration of crude cholera toxin. Values for glycerol produced during the second hour of incubation (●—●) represent data from individual incubations. Those for the third hour (○ - - - ○) are the means of the data from two incubations that agreed within < 5 per cent.

Territorial and Courtship Songs of Birds

THE usual interpretation of passerine song is that it simultaneously attracts potential mates and repulses neighbouring territory holders[1]. The male black-throated green warbler (*Dendroica virens*, family Parulidae), however, sings two similar but distinct songs[2]: song *A* (Fig. 1*a*) chiefly in the presence of conspecific males and song *B* (Fig. 1*b*) chiefly in the presence of conspecific females. There seem thus to be separate songs for territorial defence (song *A*) and courtship and pair-bond maintenance (song *B*).

A natural experiment, in which males have no neighbouring territory holders of the same species, is created by several small islands off the coast of Maine. The birds are part of the same gene pool that controls birds on larger neighbouring islands that contain many pairs of the same species. If the songs are always sung in certain contexts song *A* will be infrequent among the isolated males in comparison to birds on larger islands. Further, song *B* might be relatively more frequent during the courtship phase but less frequent during the bond-maintenance phase when the mate is constrained to the small island. I report here the results of recording the frequencies of the two song types in two representative habitats throughout the breeding season.

Table 1. SIZE AND RELATIVE ISOLATION OF FORESTS ON SMALL ISLANDS

Name of island	Size of forest (ha)	Distance to forest on nearest island containing black-throated green warblers (m)
Crane	0·53	230 m
Indian	0·69	225 m
Jim's	0·49	500 m
Thief	1·50	1,070 m

The study was conducted on Hog Island (Todd Wildlife Sanctuary), Bremen, Lincoln Co., Maine, and small islands 0·3–7·3 km away from it (Table 1). Hog Is. is largely covered with a forest of red and white spruces (*Picea rubens* and *P. glauca*) 18 to 25 m high; the habitat is described in detail elsewhere[3]. The small islands (Jim's Is., Bremen; Indian Is. and Thief Is., Bristol, Lincoln Co.; Crane Is., Friendship, Knox Co.) all contain white spruce forests superficially similar to that of Hog Is., except that in several cases the trees are shorter, and that in all cases the habitat has a high proportion of edge. These habitats will be discussed in greater detail elsewhere.

We counted songs for periods of 10 min regularly throughout the season (usually every other day), always within the hours of 0900–1100 DST. From the middle of a small island it was possible to record all the songs. Data were collected from Indian Is. and Thief Is. in 1967, 1968 and 1969; from Crane Is. in 1967; and from Jim's Is. in 1968. Six males were studied; the same birds nested on Indian Is. and Thief Is. in both 1968 and 1969. The number of songs in 10 min was counted throughout the 1966 season from a randomly selected group of 10 birds on Hog Is. Periodic counts of songs were made on Hog Is. in 1969 and indicated no apparent differences from the complete 1966 data. All individuals counted on Hog Is. were apparently mated; all isolates were certainly mated.

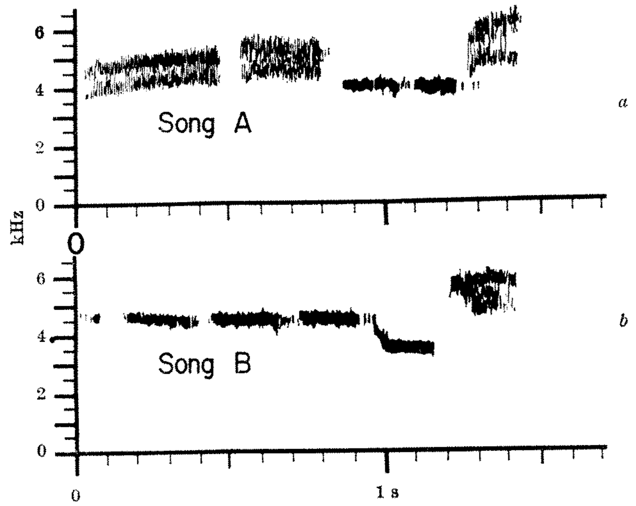

Fig. 1. Songs of the black-throated green warbler. Drawings of sound spectrograms.

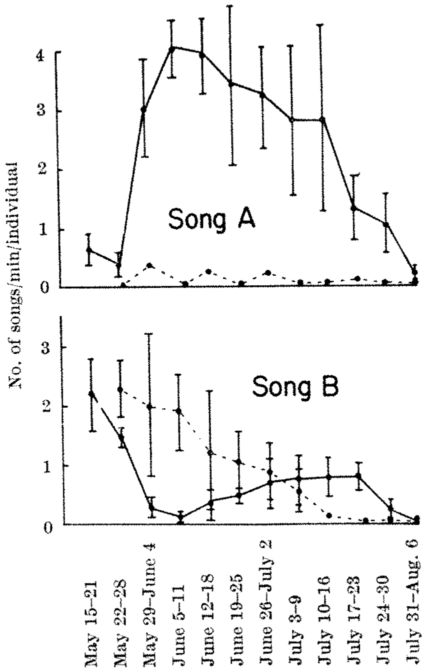

Fig. 2. Types of songs of male black-throated green warblers on Hog Island (———) and small islands (- - -). One standard deviation plotted.

The results appear in Fig. 2. Birds in large populations produced song *A* far more than isolated birds at almost any period of the season; but isolates gave more song *B* during the first half of the breeding season (and a much greater percentage of song *B*) than birds in large populations. During the last half of the season, song *B* came more from birds in large populations than from isolates. At almost all times the combined frequency of songs *A* and *B* from each bird in large populations was much greater than the frequency on small islands.

The first high frequency of song *B* occurred in the pairing period immediately after the birds arrived, with the greatest counts of song *B* at this time in both the large population and among isolates. After apparent pairing the frequency dropped precipitously in the large population, with a simultaneous increase of song *A*. In the isolates, however, song *B* remained dominant, although it declined continuously in frequency as the season progressed. If conspecifics are absent, more time should be free for other activities and, perhaps accordingly, the isolates gave a high (though declining) frequency of song *B* during the first part of the season.

The gradual but constant increase in song *B* among the large population after the early drop showed an inverse relationship to the concurrent decrease of song *A*. The basis for an almost continuous song *A* had probably declined somewhat by then. The increase of song *B* began at the peak of the incubation period, when there was little contact between sexes because only the females incubate[4].

The possible effect of congeners requires comment. In large populations three are present: magnolia (*D. magnolia*), myrtle (*D. coronata*) and blackburnian (*D. fusca*) warblers, as well as the smaller parula warbler (*Parula americana*)[3]. Myrtle and parula warblers were present on each small island studied (one pair of each species), but magnolia and blackburnian warblers never nested. The possibility thus arises that the missing species might affect the song patterns of black-throated green warblers, for the latter are not oblivious to the songs of congeners[2]. Although they did not nest, however, singing blackburnian warblers were observed three times on Indian Is. and in no instance did black-throated green warblers give song *A* in their presence. Similarly, singing magnolia warblers were observed twice on Thief Is. and once on Indian Is., and during these periods no song *A* was heard.

On the other hand, in 1969 a second male black-throated green warbler tried to establish territory on Thief Is. The resident male produced song *A* frequently when close contact was noted between the two birds (June 12–18, June 26–July 2 in Fig. 2), so that a resident male seems capable of singing this pattern in appropriate situations. Song *A* was recorded on Indian Is. between May 29 and June 4 in two different years; the resident male may have responded to an undetected male or, more likely, to songs from Loud's Is. across a 225 m gap of water and rocks. Loud's Is. supports a large population of warblers similar to that of Hog Is. When giving song *A* at these times the male from Indian Is. always situated itself on the side of the island immediately adjacent to Loud's Is.

In summary, song *A* occurred less often, and song *B* initially more often, among isolated males than among individuals in large populations. Further, among isolates song *B* became less frequent through the season until it was rarer than in large populations. My results suggest that the type of song was strongly regulated by situations experience rather than by heredity. They also strengthen the earlier hypothesis that the two songs act in different behavioural contexts.

I thank M. S. and R. W. Ficken, J. P. Hailman and W. M. Schleidt for commenting on the manuscript. The National Audubon Society permitted field work on Hog Is. and the US National Science Foundation provided support.

Semi-terrestrial Shrimp *(Merguia rhizophorae)*

IT is widely believed that there are no semi-terrestrial or terrestrial species of shrimps and prawns (order Decapoda: suborder Natantia)[1], but I now report that the shrimp, *Merguia rhizophorae* (Rathbun, 1900) (family Hippolytidae), is semi-terrestrial. It seems to have evolved behavioural adaptations which have allowed invasion of the terrestrial environment.

This shrimp was originally described from the State of Alagoas, Brazil, where it was found "on mangroves"[2]. Holthuis[3] redescribed and illustrated this shrimp from specimens collected in Suriname and determined its correct generic position, and his detailed notes support my observations on the semi-terrestrial habits of this species (see also his remarks on *M. oligodon*).

I first observed and collected *M. rhizophorae* in a mangrove area on the Atlantic coast of Panama in May 1969. A specimen was found under a dry piece of driftwood approximately 1 m above the high tide mark. When I tried to grasp it, the animal leapt onto some nearby mangrove roots, and moved up and down the roots and leapt from one root to another.

During July, I observed nineteen shrimps during the day and night, at high and low tides (representative specimens are in the US National Museum, No. 127510). All the specimens were found above the high tide mark among piles of driftwood, 0·3 to 0·5 m off the ground. The substrate, damp sand with mats of algae present, was probably wet by rainfall, seepage, or an occasional spring tide, normal tides not reaching this level. The shrimps were found under the driftwood during the day and out on the wood at night. They remained motionless when first observed, but when disturbed they leapt onto other pieces of driftwood and mangrove roots. The shrimp did not appear to orient towards the water while attempting to escape, and no specimens were seen in water nearby.

Four shrimps were placed on an unprotected cemented area for further observations. The air temperature was 31° C, wind velocity 12 m.p.h., on a partly cloudy day. The shrimps moved about in an apparently random manner. They walked in a forward direction using the last three pereiopods in a manner resembling insect locomotion. The abdomen was arched so that the body and telson were raised off the ground. Before movement, the elongate and spiniferous third maxillipeds were pressed together and extended in front of the shrimp. They were then lowered onto the substrate, and contracted. The shrimp climbed mangrove roots and wood in the same manner. The third maxillipeds were pressed together during the entire process and were re-extended onto the substrate when the shrimp became motionless. Shrimps, 10–20 mm in length, were able to leap in any direction over distances of 20–30 cm and 10–15 cm in height, the forward leaps being the longest and highest. Their motion was too rapid to determine to what extent flipping of the abdomen and using the walking legs played in leaping. The abdomen was arched high so that flipping the telson against the substrate probably began the leap, the legs then being used to direct it. The shrimps walked about until a shaded, protected area was located; then they became quiescent. They could be made to move by moving a small net to within a few centimetres of them. One specimen leapt thirty-six times during a 4 min period, sometimes without apparent provocation. Holding them in a moist beaker for 4 h did not affect their previously observed behaviour.

The general morphology of *M. rhizophorae* does not seem to be specially adapted for terrestrial habits. The eggs, however, are large (0·9 mm) compared with a closely related hippolytid *Hippolysmata wurdemanni* (0·28 mm). This suggests an abbreviated larval development, perhaps similar to *Thor* sp., another hippolytid which has a comparable egg size and undergoes metamorphosis within 48 h after hatching[4]. The pereiopods of *M. rhizophorae* are more robust than in most marine shrimps and are able to support the body on land (most shrimps, if they are able to move on land at all, drag their body). The eyes are large and may be adapted for a nocturnal existence because they possess a strong reflecting layer.

This shrimp's behaviour may be defensive. The animal seemed to avoid water, and the ones observed in Panama were never found directly on the ground. The waters surrounding the mangrove are heavily populated by predacious fish (*Lutjanus* sp.) while predacious crabs (Xanthidae) are on the ground. When pursued, the shrimp avoided these areas. The shrimp was motionless when first observed and relied on its cryptic attitude and coloration as a primary defence. Its secondary defence, leaping, was used only when the "predator" was very close. This extremely rapid leap was very effective. The shrimps can maintain this type of avoidance behaviour for more than 4 min. This is interesting because several brachyuran crabs which I examined could maintain an avoidance behaviour for only 40–90 s (M. H. Robinson, L. G. A. and B. Robinson, in preparation).

Merguia rhizophorae probably enters the sea occasionally, but only at certain times and for brief periods. My studies indicate that it remains in a moist habitat during the day and only comes out at night. It thus seems that *M. rhizophorae* avoids most problems accompanying terrestrial life through behavioural adaptations.

This work was carried out at the Smithsonian Tropical Research Institute while I was associated with the University of Panama. I thank my friends and colleagues for constructive criticism.

Development of *Dracunculus medinensis* after Freezing

I BELIEVE this to be the first report of development to maturity of a parasitic helminth after prolonged storage at low temperatures.

Among nematodes the microfilarial larvae of *Wuchereria bancrofti* were stored at −25° C in heparinized blood[1], and a few of those of *Dirofilaria immitis* developed in the mosquito, *Anopheles quadrimaculatus*, after storage[2] at −68° C. Recently, development of a few microfilariae of *Brugia pahangi* to the infective third stage in *Aedes aegypti* has been reported after storage for twenty-nine days at −79° C in serum containing 5 per cent dimethyl sulphoxide[3].

Embryos of *Dracunculus medinensis* in distilled water have been successfully deep frozen for months[4] and, after thawing, 0·05 per cent of them developed to the infective third stage in *Cyclops leuckarti* (Claus)[5].

In my experiment one batch of larvae was obtained from a patient in Western Nigeria in May 1966 and another from an experimentally infected rhesus monkey in June 1969. They were cooled slowly (5° C/min) to −78° C in ampoules containing about 2,000 embryos per ml. of sterile distilled water without additives (glycerol and dimethyl sulphoxide were deleterious). Embryos were thawed quickly at 37° C and left for two hours at 30° C before being used for infecting *Cyclops vernalis americanus* (Marsh). Infected cyclops were maintained for fourteen days at 26° C and then kept for two hours at 37° C in normal saline containing 0·01 per cent HCl. Twenty-five infective third-stage larvae were released from cyclops infected with embryos stored for 6 months (1 per cent infection rate) and one larva from a cyclops infected with embryos stored for 40 months. This is a very low recovery compared with the 80–90 per cent infection rate and average of two larvae per infected cyclops found when using freshly obtained embryos[6]. The released larvae were injected intraperitoneally into a young male rhesus monkey (*Macaca mulatta*) and the remaining cyclops (probably containing a few more larvae) were given by gavage.

Male worms reach maturity after seventy to eighty days in the rhesus monkey (mean size 14 mm, *SD* 1 mm) and die three to seven months after infection. The monkey was therefore killed ninety-four days after infection; two female worms (measuring 24 and 15 mm) and three males, two alive (15 and 12 mm long) and one dead and encapsulated, were recovered from the subcutaneous connective tissues of the abdomen and thorax. The females had been fertilized and appeared normal histologically. They were small for their age (normal mean estimated at 35 mm; mean at 77 days 22 mm, *S.D.* 3 mm), although there is wide variation during this period of rapid growth. The living males were fully mature and of average size.

Dracunculiasis is still a major medical problem in parts of Africa and Asia and, although there have been several reports of successful treatment with niridazole[7-9] as a result of therapeutic trials in man, there has been no readily available laboratory model in which to study its mode of action.

Freezing of embryos for subsequent infection of cyclops should prove useful in the laboratory maintenance of the parasite, which has so long an incubation period and such a short period of patency in the laboratory host. It may also be applicable to other parasitic nematodes with free-living larvae.

Parallel Evolution in Leaf Venation: an Alternative View of Angiosperm Origins

MELVILLE[1] advanced the hypothesis that leaf venation patterns of flowering plants provide a body of evidence suggesting the origin of angiosperms from the Permian *Glossopteris* and its allies, which flourished on the old continent of Gondwanaland. He shows that *Glossopteris*-like venation patterns are encountered in several living angiosperms, and emphasizes that most significant examples are found in regions which once constituted the Gondwanaland continent. His argument hinges on the extent to which these venation patterns can be said to resemble closely *Glossopteris* rather than other gymnosperm leaf types. This proposition can seriously be called in question.

Melville has also suggested[2-4] that the fructifications of some Glossopteridae, as reconstructed by Plumstead, have features in which they resemble the "Gonophyll"—the basic morphological unit of Melville's new theory of angiosperm flower structure. The proposition of the derivation of angiosperm leaf architecture from that of the *Glossopteris* leaf type is advanced independently of this, on its own merits, and can reasonably be judged on this basis.

Melville suggests that the Glossopteridean leaf is characterized by a "syndrome" of vein junction patterns (his Greek alphabet configurations are reproduced here in Fig. 1*E*), and that these are "associated together only in the Glossopteridae and in the more primitive leaf types of the angiosperms. Some of the characters occur in other groups, notably ferns and pteridosperms, but combined in different combinations to form other distinctive syndromes". Fig. 1 illustrates four leaf venation patterns selected from four different orders of fossil gymnosperms (Pteridospermales *sensu stricto*, Caytoniales, Cycadales and Bennettitales) each of which is believed (from evidence of the other parts of these plants) to be at least as remote from the Glossopteridae as they are from one another and from the angiosperms. All possess an impressively high proportion of vein junctions of the "glossopterid syndrome". While this venation syndrome is quite distinctive, and differs from that of most living angiosperms, it is matched closely in these several unrelated lines of gymnosperms, and indeed in several other groups of plants. On venation pattern alone there is no closer similarity between *Glossopteris*-like angiosperms and *Glossopteris* than between these and the four orders of gymnosperms illustrated.

It seems that one cautious conclusion can reasonably be drawn: the number of ways of developing a net-veined leaf from an initially dichotomizing system is limited. The "glossopterid syndrome" is part of a well-trodden evolutionary pathway, followed by several other groups. We clearly cannot use venation alone as a basis for reading angiosperm ancestry back into the Glossopteridae. As Melville notes, Foster has argued convincingly that some primitive living Ranales with an open (dichotomizing) venation pattern represent a primitive state within the angiosperms; so that if a single evolutionary origin is accepted for the angiosperms—a point on which we would agree with Melville—it seems likely that net venation developed within the group, probably some time in the Mesozoic, rather than having been already possessed by their putative Permian precursors. It is not suggested here that the rather widespread occurrence of the "glossopterid syndrome" rules out the possible derivation of the angiosperms from that group. It can only be argued that gross venation patterns present too little diversity, and are arrived at too readily by more than one evolutionary pathway, to form a valid basis for any phylogenetic conclusions.

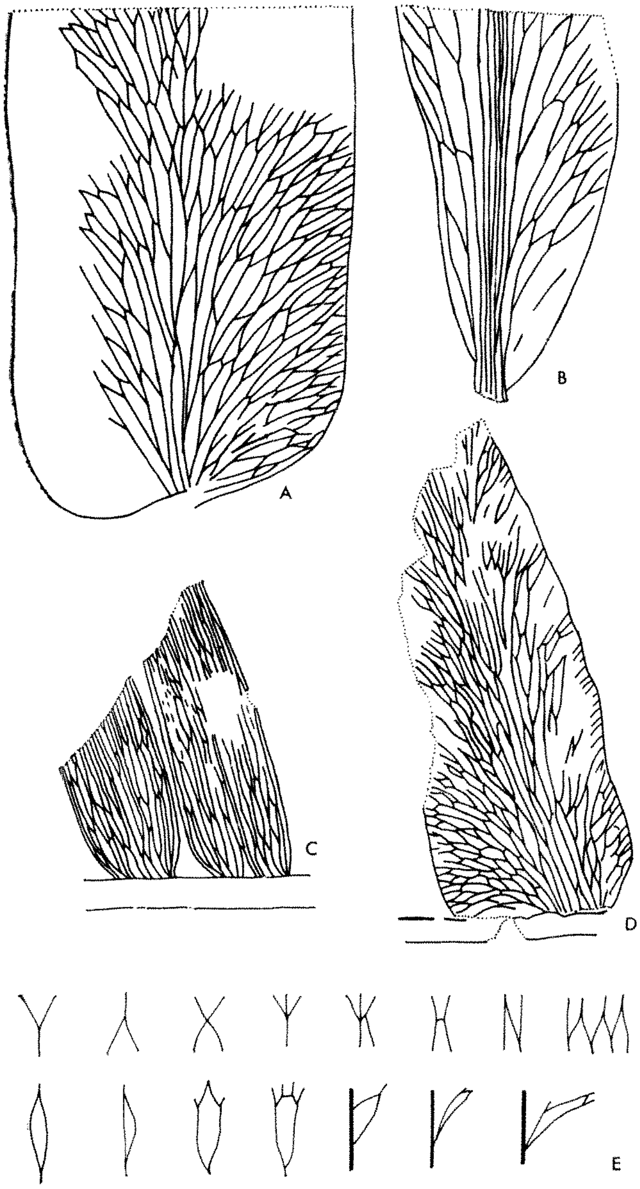

Fig. 1. Four different types of fossil gymnosperm leaf belonging to different orders, all with a significant proportion of vein junctions of the "Glossopterid syndrome" (*E*). *A*, Base of pinnule of *Linopteris obliqua* (Pteridospermales, Upper Carboniferous, × 4); *B*, base of leaflet of *Sagenopteris phillipsi* (Caytoniales, Middle Jurassic, × 4); *C*, bases of pinnae of *Ctenis kaneharai* (Cycadales, Middle Jurassic, × 1); *D*, *Dictyozamites hawelli* (Bennettitales, Middle Jurassic, × 4). (*A*, After Crookall[5]; *B* and *C*, after Harris[6]; and *D*, after Harris[7].)

Whether or not the reproductive structures of Glossopteridae are at all angiosperm-like is a closely related but none the less separate issue. But until more is known about this aspect it seems unfortunate to allow *Glossopteris* and its allies to hold the undivided attention of botanists as the principal candidate for the source of the angiosperms, for there is still woefully little evidence pointing to a solution to this problem.

Reply to Criticism of Hypothesis of Leaf Venation and Angiosperm Origins

Alvin and Chaloner's criticism of my ideas about leaf venation patterns seems to be based chiefly on the distribution of vein junction types to the exclusion of associated vein island types. It is necessary to emphasize, therefore, that the glossopterid syndrome includes characters belonging to both of these categories. From the phylogenetic standpoint the important correlations are those between the complete syndrome and the major taxa: Angiospermae, Glossopteridae, Pteridospermae, Cycadales, Bennettitales and Caytoniales. Parts of the syndrome are lacking from all of these groups except the first two. What the critics do show is that similarities in the venation systems extend beyond that of open dichotomy—the *Ginkgo* and *Circaeaster* stage—as far as the *Gangamopteris* stage. We can agree to parallel evolution in these groups up to the *Gangamopteris* stage. Confining the discussion, for the moment, to leaf characters, there are some other features to be taken into account. The examples cited for the Pteridosperms, cycads and Bennettitales are all of leaflets of compound pinnate leaves, whereas the comparison was made between simple leaves in the Glossopteridae and Angiospermae. Compound pinnate leaves occur frequently in only about 20 per cent of angiosperm families and in many of these there is internal evidence of a derivation from simple leaves. One exception, the Quiinaceae, has already been commented on. The only other major exception is the Leguminosae in which the evidence is consistent with the persistence of compound leaves since the glossopterid phase of evolution.

The fourth example, *Sagenopteris* from the Caytoniales, is of a leaflet from a compound digitate leaf with a venation pattern representing an evolutionary stage between that of *Gangamopteris* and *Glossopteris*. The midrib is poorly developed, being a loose aggregation of parallel veins, and the principal vein islets are of the hydroid type which in the evolutionary sequence is one of the first to appear in *Gangamopteris*. Moreover, these vein islets run almost parallel with the midrib, whereas in the more advanced species of *Glossopteris* the principal vein islands along the midrib are of arcuate, angular or deltoid types and they make angles of about 70°–80° with a compact well formed midrib. The latter three types of vein island are the most advanced elements in the glossopterid syndrome. They must carry considerable weight in assessing probable angiosperm affinities with the Glossopteridae, for they occur in several angiosperm families in a similar relationship to the midrib of a simple (not a compound) leaf. Unless it can be shown that the more advanced types of vein island occur in the same kind of relationship in the other four orders of gymnosperms, the claim of Alvin and Chaloner that "on venation pattern alone there is no closer similarity between *Glossopteris*-like angiosperms and *Glossopteris*" than between these and the other major taxa cannot be maintained.

Identification of Polychlorinated Biphenyls and DDT in Mixtures by Mass Spectrometry

Recently it was recognized that certain chlorinated aromatic compounds, particularly polychlorinated biphenyls (PCBs), are found in natural samples as pollutants[1,2]. PCBs interfere with the analysis for chlorinated pesticides because some of the PCB components from the technical mixture have identical retention times and respond to the electron capture detector[3,4].

Although combined gas chromatography–mass spectrometry for detection of PCBs from natural samples has been described[5], the use of mass spectrometry, particularly high resolution techniques, for the unambiguous identification of PCBs in the presence of chlorinated pesticides without previous separation[6] has not been reported.

We have recorded the mass spectra of a commercial sample of PCB ('Aroclor 1242') in different conditions and obtained high resolution measurements to confirm the molecular formulae of major components. The peaks arising from the individual major components of the mixture were as follows. $C_{12}H_8Cl_2$: found, 222·0000; calc., 222·0000. $C_{12}H_7Cl_3$: found, 225·9614; calc., 255·9610. $C_{12}H_6Cl_4$: found, 289·9220; calc., 289·9220. $C_{12}H_5Cl_5$: found, 323·8829; calc., 323·8830. (The experimental error is within ± 2 p.p.m. in all cases.) These can easily be distinguished from major peaks found in the most common chlorinated insecticides (Fig. 1 and refs. 6–13) by their position, peak pattern arising from the chlorine isotopes and particularly high resolution measurements. Furthermore, a useful spectrum of 'Aroclor 1242' can be obtained at low temperatures by direct introduction with the aid of a temperature controlled probe[14], and fractional sublimation from many chlorinated pesticides directly in the ion source seems possible (see Fig. 1).

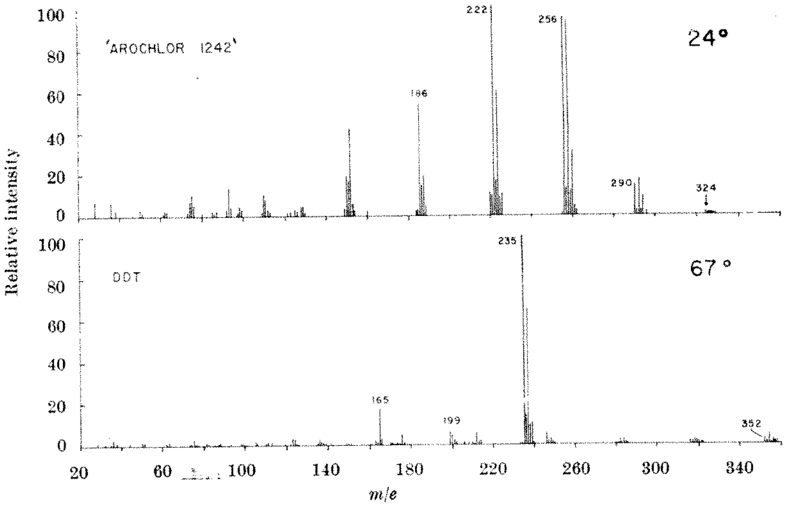

Fig. 1. 70 eV mass spectra (C.E.C. 21–110B instrument) of a 1 : 1 mixture of 'Arochlor 1242' and DDT at different sample temperatures. Isotope clusters at *m/e* 222, 256, 290 and 324 result from individual components of 'Aroclor'; the group of peaks at *m/e* 186 are mainly fragment ions from this substance.

Techniques for identification of trace quantities of PCBs and chlorinated insecticides in crude natural samples and their semiquantitative determination by mass spectrometry as well as the chemical characterization of major constituents of PCBs are being developed.

We thank D. J. Embree for recording the mass spectra.

LUMPS AND LOCALIZATION

Mind, Brain and Adaptation in the Nineteenth Century

Cerebral Localization and its Biological Context from Gall to Ferrier. By R. M. Young. Pp. xiv + 278. (Clarendon Press: Oxford; Oxford University Press: London, January 1970.) 65*s*.

THIS volume has attempted to record the development of ideas of cerebral localization in the nineteenth century, devoting major emphasis to Gall, Flourens, Magendie, Mueller, Bain, Broca, Spencer, Jackson, Carpenter, Fritsch and Hitzig, and finally Ferrier. It was clearly Gall who most intrigued the author, and we are indebted to him for a careful refutation of the common error of regarding the founder of phrenology purely as a charlatan. Young attributes to him the first empirical approach to the relationship between the functions of the brain and their localizations, and shows him as an able anatomist and a careful clinical observer of certain aspects of aphasia many years before Broca. Furthermore, he shows that while Gall stressed complex behaviours at the neglect of physiology, the experimental successes of later workers such as Ferrier led to the too ready assumption that the higher activities could all be compounded out of elementary motor and sensory components.

The debate on localization is one that will obviously go on for many years. Nearly all of the major approaches to it were developed during the nineteenth century. Young points out that no complete history of the problem has been available. His work, by thoroughly covering most of the important figures and problems, is therefore important. My only objection to his treatment is in certain omissions. This probably results from his admitted reliance for certain portions of his account on secondary sources. He has drawn very heavily on Henry Head, whose famous and undoubtedly influential discussions many of us would regard as biased, inaccurate and indeed contradictory because he himself ended up by supporting localizations which he had rejected violently earlier in the same volume.

This heavy reliance on secondary sources may account for the fact that, except for Broca and Fritsch and Hitzig, Young neglects almost entirely the contributions of the French and especially the Germans in this field, accepting the common bias in much of the literature in confining himself almost entirely after 1870 to English writings. He draws heavily on Hughlings Jackson, but neglects the fact that his influence outside England was not great, and that he was not well known in German circles until Sittig's translation of some of his writings many years later. By contrast, Meynert, whose comparative anatomical studies correlating structure and function, and whose division of fibre tracts of the brain into projectional, associational and commissural systems, so profoundly influenced German ideas on localization, is given only a few lines. Carl Wernicke, whose monograph of 1874, with its detailed discussion of localization theory and its special stress on anatomical connexions between cortical regions, dominated much of Continental thought in this field for the next half century, is mentioned only in a footnote.

This reliance on Head may also explain why Young probably underestimates the importance of the problem of aphasia in the history of theories of localization. He admits that Broca's discovery of a localized region for speech was the first functional localization which met with general acceptance by the scientific community. The acceptance of Wernicke's views was almost equally dramatic, because he was the first to provide and set up a plausible theoretical basis for the anatomical localization of language functions, from which he and his students claimed that it was possible to predict the existence of new forms of aphasia. Speech functions remained as a critical facet of most discussions of localization. Even the extreme holist could come to accept cortical sensory and motor systems by regarding them essentially as peripheral instrumentation, but he continued to balk at the idea of localizations for psychological functions, such as language. It was even possible for Sherrington to establish a reflex physiology of the spinal cord and brain stem and to be unaware that attempts at analysis of higher functions had, in fact, been more sophisticated than a simple phrenological model.

Young argues, in my view correctly, that a knowledge of the history and awareness of philosophical problems in this area is important for future advances. He has contributed importantly to this end, and one can only hope that he will look more fully in the future into the Continental contributions of the period 1870–90 to the controversy on ideas of localization.

NORMAN GESCHWIND

THE SOCIOLOGY OF FOOD

Man and Food

By Magnus Pyke. Pp. 256. (Weidenfeld and Nicolson: London, April 1970.) 35*s*.

INFORMED discussion about the food supply of a community is dominated by three equally important factors: how much of each of the known components of a diet is needed; how can the necessary quantity be supplied; how can we ensure a proper distribution so that everybody gets as much as is needed? Pyke deals with all three themes in a lively and humane manner. His book contains so much information and has so many merits that it deserves to be widely read. Nevertheless, it has some unevennesses. It is odd to find two pages devoted to the structural formulae of volatile oils and terpenes and one to the amino-acids, but no vitamin structures. Had he included the last, the meaning of niacin would have been clear. The word was invented because one group of manufacturers had difficulty persuading people (who probably did not need vitamin supplementation anyway) to buy nicotinic acid when other manufacturers were persuading them that nicotine in tobacco was harmful. Niacin is now acceptably defined as a blanket word for the acid and amide.

Two chapters on animal products explain, among other things, that the depletion of glycogen in an animal killed after a struggle diminishes the formation of lactic acid which inhibits bacterial growth. Hence the better keeping qualities of properly slaughtered meat and the poor keeping qualities of fish, which always die after a struggle. These chapters also explain the merits, and demerits, of cheese; the losses that are entailed in using animals to convert the protein in their food into the product that we eat; and the possibilities of using some at present wild animals. There is a brief chapter on cereals, vegetables and fruit.

Pyke argues convincingly that starvation and malnutrition usually have a political origin. It was the rapacity of landlords that forced the Irish to rely so completely on potatoes that the outbreak of blight in 1845 was devastating, and it is lack of money rather than inability to grow food that causes much present-day malnutrition. In the light of this conclusion it is a pity that he does not comment on the fact that FAO, in its "Provisional

Indicative World Plan for Agricultural Development", limits discussion to effective economic demand rather than need. He points out that gifts of food to countries with malnourishment often do more ultimate harm than good, and suggests that it would be better so to organize things that the people of these countries could earn more money and buy the food. It would seem to be still better so to organize things that they can grow the necessary food locally.

People with a mystical belief in "natural" foods are roundly trounced, and many examples are given of the indubitably beneficial effects of food processing. Examples are also given of potentially harmful processing undertaken for trivial or purely commercial reasons. Pyke recognizes that one cannot generalize about the activities of food manufacturers. They need watching, but the watchers should not become paranoid. The standards that are sometimes now set would have condemned rhubarb, and even perhaps the potato, had they operated when these plants were introduced into Europe.

An excellent final pair of chapters discuss population problems and the potentialities of synthetic foods, the extraction of leaf protein, and the cultivation of edible microorganisms on agricultural wastes and petroleum. Here, and at many other points in the book, Pyke stresses the need for greatly increased research; we know, for example, very little about the food needs of the elderly. He shows commendable scepticism of the simple explanations sometimes given for recent population increases and argues that they are not caused simply by medical progress but by many forms of technological innovation. A little technological change is welcome, but he sees the risk that too much may make life unbearable and produce plethora —not just of food, but of noise, crowding and pollution as well. N. W. PIRIE

TOOLS FOR PLANT BREEDERS

Induced Mutations in Plants

(Proceedings of a Symposium on the Nature, Induction and Utilization of Mutations in Plants, jointly organized by the IAEA and FAO, and held at Pullman, Washington, 14–18 July 1969. Proceedings Series.) Pp. 748. (International Atomic Energy Agency: Vienna; HMSO: London, 1969.) 517 schillings; 166*s* 8*d*; $20.

MUTATIONS occur spontaneously, but rarely. Radiation and mutagenic chemicals are tools with which the plant breeder may induce more variation for selection, but mutations are chance events and, unless understood and controlled, induced mutations as a weapon in the breeder's armoury might be compared with trying to hit the bullseye with a shotgun; one may be successful but the target has to be rebuilt. This book constitutes the published papers of a symposium intended to review our understanding of the use of induced mutations in plants.

The symposium was divided into seven sections. Section A consists of nine papers on the nature of mutations, genetics and biochemical pathways; section B, fifteen papers on the action of physical and chemical mutagens; section C, four papers on the induction of mutations and breeding methods in vegetatively propagated species; section D, fifteen papers on induced mutations and breeding methods in seed-propagated species; section E, seven papers on the utilization of mutations for general and evolutionary studies; section F, three papers on the use of chromosome aberrations in breeding; and section G, three papers on new induced mutant varieties. Of the fifty-eight papers, fifty-two are in English and all are preceded by brief summaries in English. Excepting D and E, the first paper in each section is chiefly devoted to a comprehensive review (with extensive bibliography) of the topic under discussion.

The papers in section A provide evidence for increasing sophistication of techniques. R. D. Brock's paper on "Increasing the Specificity of Mutation", for example, describes experiments with ***Escherichia coli*** which indicate that certain mutagens will mutate an active gene more readily than when it is inactive. Also, by using the regulator protein of the lactose operon, made mutagenic by incorporating ^{35}S and ^{3}H amino-acids, he opens up the prospect of inducing mutations at particular loci. If similar systems are operative in higher plants, refined control of the mutagenic processes may be possible.

References to the successful use of induced mutations are many. These include the use of neutrons and X-rays to induce *Verticillium* resistant strains of peppermint, by M. J. Murray (section C); the use of X-ray induced translocations to produce the first commercial F_1 hybrid barley, by R. T. Ramage (section D); the ability to increase the yield of barley some 10 per cent above that of the mother variety, described by members of the Max Planck Institute (section D); not to mention the scores of released crop varieties described and listed in section G.

In section E, along with papers on the "Tetrasomic Heredity of Induced Mutations in *Arabidopsis thaliana*" and the "Nature of Chromosome Deletions", R. F. Stettler and co-workers discuss the interesting possibility of producing homozygous forest trees by induced haploid parthenogenesis. The diversity of the papers in section B supports the view of M. S. Swaminathan that breeders should continue to use a wide range of mutagens.

These proceedings may be of particular interest to British plant breeders who, in a list of one hundred and one participants from twenty-five countries, are sadly noticeable by their absence. G. R. MACKAY

ESSENTIAL NUTRIENTS

Trace Elements in Agriculture

By Vincent Sauchelli. Pp. viii+248. (Van Nostrand Reinhold: New York and London, January 1970.) 140*s*.

VINCENT SAUCHELLI died in autumn 1969 after a long life in agricultural science, latterly in association with the American fertilizer industry. This is his last book; it was written as a survey for the general reader and student and as background information for advisers, teachers and fertilizer manufacturers who meet trace element problems in their daily work. It succeeds in these aims.

The first five chapters are introductory. They describe the historical background to trace element research, and biological and physico-chemical relationships of crops and soils involving trace elements. This information is simply but accurately presented and will be useful to both students and to those who need to refresh their memories.

Six chapters follow on the trace elements or micronutrients which are well recognized as being essential to plants—iron, manganese, boron, zinc, molybdenum and copper. These chapters have a general pattern. Sources of trace elements in soils, the effects on plants of deficiencies and surpluses, and the effects of each element on animal health and nutrition are described. The methods used to correct deficiencies are discussed well; the tables setting out recommendations for different crops and soils in parts of the United States are particularly valuable features of some of the chapters. There is a chapter on chlorine, the latest element to be accepted as essential for plants, but which is much more important in animal nutrition and health.

Sodium seems to be essential for a few plants and can substitute for potassium in others. There is a chapter on sodium, but it gives very little information about the importance of this element in animal nutrition. But sodium is hardly a trace element, either for plants or animals, and the account is out of place in this book.

Following chapters deal with selenium, cobalt, iodine and fluorine; all of these are essential to animals and cobalt is essential for leguminous plants. There are brief accounts of the possible effects on plants and animals of nickel, lithium, vanadium, silicon and aluminium.

The text is concluded with a brief but wise discussion on correcting trace element deficiencies, and the possibilities of incorporating them into mixed fertilizers supplying major nutrients. Sauchelli did not recommend "shotgun" applications where deficiencies had not been diagnosed. There is a list of commercial American producers of trace elements and methods of analysis are briefly described.

It is a relatively short book, but sufficient for agricultural students and it is recommended to them. Advisers and research workers with trace element problems will have use for the accounts of deficiencies and methods of correcting them. Further information can be got from the numerous references. Sauchelli read widely and European literature is well represented in the bibliographies (this is not always so in American books on agricultural science). The book is well printed, but the black-and-white illustrations of deficient plants are little help (there are no colour plates). It is very expensive and the price will prohibit purchase by many who would find it useful.

G. W. COOKE

COMPARTMENTAL ANALYSIS

Multicompartment Models for Biological Systems

By G. L. Atkins. (Methuen's Monographs on Biological Subjects.) Pp. xiii + 153. (Methuen: London, November 1969.) 35*s*.

WHEN a substance such as a radioactive tracer is introduced into a biological system, its concentration in any particular part of the system may first rise and thereafter declines asymptotically to a steady level, which may be zero. Such a curve can usually be fitted empirically by super-position of a few exponential components. This, as it happens, is exactly the behaviour of a tracer in a system consisting of a number of well mixed pools or compartments which interchange material with each other at a constant rate; the number of exponential components is one fewer than the number of compartments (which may possibly include the external environment). Compartmental analysis consists in the derivation of concentration curves for various models and conversely in the devising of models to fit experimental concentration curves. There is a temptation to identify the compartments arising from the analysis with the recognizable anatomical divisions of the biological system. This identification, however, is open to the objection that there is very great latitude in fitting functions to a set of experimental points subject to even moderate error. Given *a priori* knowledge of the number of compartments there is very great imprecision in determining the size and exchange rate of any one of them. Moreover, there is seldom any guarantee that an anatomical division behaves as a single homogeneous compartment, and even if one component more than the minimum required to achieve a satisfactory fit is introduced, the range of possible combinations of functions is further enormously increased.

These considerations, which a little experiment will easily verify, might well cause a reader to doubt whether the process of compartmental analysis is of any scientific value, and if he approached Dr Atkins's book in this frame of mind, he would find little to dispel his scepticism. This is the weakness of the book; it deals too briefly with the very matter for which there is the greatest need, the appraisal of the validity of the solutions obtained. The chapter on treatment of experimental data and curve fitting is decidedly thin. In fairness to the author, however, a really adequate treatment would need to be quite elaborate, possibly too elaborate for the audience he has in mind.

The book does not attempt a formal exposition of the subject, such as is already available in essence in the usual texts on differential equations; it is rather a survey of the techniques of compartmental analysis and of their fields of application. This is supported by a fairly extensive and well chosen bibliography. A non-rigorous mathematical treatment is introduced as required, with a brief treatment of the differential operator, D, and of the Laplace transform given as an appendix. This approach will probably be congenial to a reader with some mathematical equipment who wishes to comprehend the general mathematical strategy without actually becoming expert himself. Such a reader will be glad of the chapter on simulation techniques in which methods of obtaining analogue representatives are described. The use of digital computers is only touched on, but sufficient references are given to lead the reader towards the help he may need.

E. W. EMERY

TISSUE INCOMPATIBILITY

Immunogenetics of Tissue Transplantation

By A. Lengerová. (North-Holland Research Monographs Frontiers of Biology, Volume 16.) Pp. xv + 270. (North-Holland: Amsterdam and London, 1969.) Hfl. 45; 126*s*.

As Dr Alena Lengerová explains in her welcome book, immunogenetics used to be thought of largely as the application of immunological techniques to the solution of genetical problems. This is no longer so, for the study of tissue and organ transplantation (with its extension into the fields of auto-immunity and tumour immunology) is now a science in its own right in which an understanding of the genetical control and inheritance of cellular antigens is of paramount importance. It is entirely appropriate that immunogenetics should provide us with such a fine example of hybrid vigour: here, two branches of science converge and interact in the liveliest manner, and we need hardly be surprised that this interaction has been so outstandingly fruitful.

The book arose from a lecture course given by this Czech scientist in 1968 at the University of Indiana and it was never intended to embrace the whole field; it does not, for example, include, except in passing, the genetics of human blood groups or of allotypic determinants. Instead, the author sticks closely to her brief of analysing the immunogenetics of the cellular antigens responsible for the induction of tissue incompatibility, and this she does superbly well. It seems nevertheless surprising that she has not devoted a chapter to the genetics of human transplantation antigens: although (and perhaps just because) this new branch of immunogenetics is still in a relatively rudimentary state it would have been most helpful to the general reader to have had the benefit of Dr Lengerová's guidance and critical appraisal.

The H-2 locus of the mouse—that much studied histocompatibility locus controlling the appearance of the strongest and therefore, by definition, the most important transplantation antigens—is naturally given pride of place. Dr Lengerová does not scorn a historical account when required, and it is good to be reminded of how much we owe to the work of the late P. A. Gorer and to G. D. Snell and their colleagues. While never oversimplifying, the author frequently finds it necessary (and understandably so) to get down to first principles, and it is this quality of lucid exposition that will make this book a valuable reference text, not only for immunologists but also for students of genetics, biology and kindred subjects. When first coming to grips with immunology, students are frequently astounded by the relative lack of hard data and the numerous rival theories; in immunogenetics, too, there are glaring gaps in our knowledge. For example, we still do not know with any degree of certainty just how the H–2 system is organized and how it operates. Is it one locus with multiple alleles and a single as opposed to several mutational sites per allele, or is it a cluster of closely linked loci, each with a number of alleles? Or are the manifold specificities generally ascribed to the H–2 locus the result of some kind of interaction between the gene product of the H–2 locus and those of other loci? Dr Lengerová discusses these various possibilities in some detail and she presents the evidence from which all at present derive some measure of support.

Another topic dealt with in depth is that of the male-linked histocompatibility antigen, namely, the antigen responsible in many inbred strains of mice for the rejection of male skin grafts by female recipients. In the literature this is generally referred to as an antigen controlled by a gene carried on the *Y* chromosome, and certainly the experiments of F. Celada and W. J. Welshons and others provide strong (if not conclusive) evidence in favour of this hypothesis and against its rival, which would explain the presence or absence of the male-specific antigen in terms of the absence or presence of the second *X* chromosome. The situation is nevertheless complicated by the demonstration that neonatal orchiectomy in some measure inhibits the phenotypic expression of this antigen, namely, that the presence of male hormones is required early in life if the antigen is to be fully developed (orchiectomy 10 days after birth having no effect).

Dr Lengerová devotes other chapters to topics such as tumour-specific antigens, the thymus-leukaemia (TL) antigenic system of the mouse, the development of histocompatibility antigens, the concept of "strong" and "weak" antigenic differences, antigenic mutation, estimation of the number of H-loci, the biological role of H-antigens, the phenomenon of allogeneic inhibition, and the peculiar status of the foetus that permits it to escape immunological attack by the mother. The book as a whole is written in impeccable and lucid English, and the reader has cause to be grateful to the author for dealing with a difficult subject with such clarity and authority. The publisher has produced the book very competently: my only criticism here is directed at the very inadequate index, which is almost entirely based on authors rather than subjects—and the price.

Leslie Brent

REPRODUCTIVE ENDOCRINOLOGY

Immunoassay of Gonadotrophins

Transactions of the First Symposium held in Stockholm, September 23–25, 1969. Edited by E. Diczfalusy, assisted by A. Diczfalusy. (Karolinska Symposia on Research Methods in Reproductive Endocrinology.) Pp. 382. (Reproductive Endocrinology Research Unit: Stockholm, 1969.) n.p.

This book is comprised of papers describing up-to-date methods in the field of immunoassay. The volume, a result of active collaboration between the Karolinska Institute and the World Health Organization, has been published within four months of the symposium and is distributed to the libraries of every medical school in the world "in order to stimulate new scientists to enter the field", and to form a basis for the development of new methods of assay in reproductive endocrinology.

The chemistry of gonadotrophins in relation to their antigenic properties is described. As well as some chemical differences between follicle stimulating hormone (FSH), luteinizing hormone (LH) and human chorionic gonadotrophin (HCG), each hormone seems to have antigenic groups which are distinct from those parts of the molecule which are essential for biological activity. There are immunological similarities between some of the human anterior pituitary trophins, which makes it difficult to produce antisera useful in specific assays; the immunological cross-reaction between HCG and LH is also well established. The preparation of radioiodinated human LH and FSH is described, as also are the inaccuracies due to iodination damage to the hormone and the effects on precision and sensitivity caused by the immunoreactivity of the labelled preparation used. It is essential that a labelled hormone to be used as tracer should be of high specific radioactivity and that both the hormone to be measured and the standard should displace the tracer in an identical manner.

A variety of methods have been used for the determination of gonadotrophins in both plasma and urine. Agglutination inhibition reactions (using erythrocytes or latex particles for sensitization) and complement fixation tests have been used as a guide in both normal and abnormal pregnancy. The use of chromatoelectrophoresis or antibody coated disks and tubes for the separation of antibody-bound and free labelled hormone in the assay of LH and FSH in clinical application is discussed. Immunosorbents with high stability, high capacity to bind antigen and little tendency to non-specific adsorption of proteins and polypeptides, can be coupled covalently to insoluble polymers to form stable conjugates with retention of immunological binding capacity. The double antibody technique is very simple to use—its disadvantages are the difficulty in assessing damage variability from serum to serum, variability with different lots of second antibody and the necessity of assessing the specificity of the assay with each amount of carrier protein used.

This is the first time that various methods of immunoassay of gonadotrophins in body fluids have been brought together—the book will serve as a stimulus to further work in a relatively new field. As yet no single technique satisfies all the criteria needed for an assay for routine clinical work and reproduction research—namely, one which uses small samples of fluid, is simple, specific and reproducible. In general, similar patterns of LH and FSH in serum during the menstrual cycle have been obtained from different laboratories, but there is a significant variation in quantitation in different parts of the cycle (and especially of the mid-cycle peak of LH) probably as a result of variations in methodology. It is essential that reliable standards are established and, in particular, a separate standard for urine and pituitary (or serum) gonadotrophins must be used, because gonadotrophins in urine seem to have lost some of their immunological potency—possibly as a result of the metabolism of the hormones—leading to a variation in the results when assayed against a pituitary standard.

May Reed

MUSCLE MOVEMENT

Muscles and Movements

A Basis for Human Kinesiology. By M. A. MacConaill and J. V. Basmajian. Pp. viii + 325. (Baltimore, Maryland: Williams and Wilkins, 1969. Distributed in the UK by Livingstone: Edinburgh.) 90*s*.

The ultrastructure and electrophysiology of muscles having held the stage in recent years, it should now be a pleasure to read a book in which the functional need for these structures in man is examined. The pleasure is unfortunately mixed with some concern and irritation. The book falls fairly clearly into two parts. The first is an introduction to the theory of kinesiology based on the geometry and mechanics of bone and joint movement. It is presented as a statement of fact and with such authority that little room for doubt, discussion or even bibliographic support seems necessary to the authors. No hesitation is shown in coining new words or substituting unfamiliar for familiar terms. Swing, slide and spin provide a pretty example of alliteration but become confusing in practice, and the use of the term "myone" for motor unit has little advantage. An attempt has been made to simplify the mathematics of the subject, but this is marred in more than one place by inaccuracies in the text and the use of diagrams which, in spite of the authors' exhortation, do not clearly indicate all the forces involved in a mechanical problem. Physiology, apart from a possibly misleading reference to the lengthening of a muscle fibre "by simple relaxation", is intentionally ignored and as a result the impression is gained that the design of muscles is determined only by their geometry.

The remainder of the book is a useful summary of contributions made to the study of muscle action *in vivo* which have not yet been incorporated into standard texts. Many of these contributions have been made by the authors themselves and adequate reference is given to others working in this field. Old and new theories are discussed in the light of electromyographic findings and admission is made where these have yet to provide a complete answer.

In a final short section on "applications and problems", acknowledgment of the variability of human nature and physique must provide little to convince many of the readers at whom this book is aimed that their labour has been worthwhile. Reference to the book in the teaching of human morphology will, however, help in the selection of detail of practical value and give rhyme and reason to the variety of musculoskeletal design in man.

E. C. B. HALL-CRAGGS

CRUSTACEAN TAXONOMY

Treatise on Invertebrate Paleontology

Part R: Arthropoda 4. Directed and edited by Raymond C. Moore. (Prepared under Sponsorship of the Geological Society of America.) Vol. 1: Pp. xxxvi + 398. Vol. 2: Pp. ii + 399–651. (Geological Society of America: Boulder, Colorado; University of Kansas: Lawrence, 1969.) $19 the two volumes.

THESE long-awaited and most welcome volumes of the *Treatise on Invertebrate Paleontology* are noteworthy for the large panel of distinguished palaeontologists and neontologists who have contributed to them. The panel is composed of the seventeen authors and a large number of other specialists who have advised or assisted. The present two volumes are devoted to Crustacea (except Ostracoda, which are dealt with in part Q which has already been published) and Myriapoda; a third volume on the Hexapoda is in course of preparation.

As in the other parts of the treatise the essence of the volumes is a presentation of the current views of the individual authors regarding the classification of the Crustacea and Myriapoda, with a concise diagnosis for each taxon down to generic level. For this reason alone they become definitive works and an essential source of reference for those working on crustacean taxonomy. But, more than this, a large part of these particular volumes is devoted to accounts of the morphology, ontogeny, mode of life and stratigraphy of the classes, which with good bibliographies make them invaluable source books for students of zoology as well as palaeontology.

Although they form part of a palaeontological treatise, these volumes acknowledge the fact that there has been a major difference of views between palaeontologists and neontologists regarding the evolution of the Crustacea, and each camp has its own version of a natural classification. Thus it is of particular interest that two of the most stimulating contributions to the volumes, both by Sidnie Manton, are devoted to an "Introduction to Classification of Arthropoda" and to the "Evolution and Affinities of Onychophora, Myriapoda, Hexapoda and Crustacea". Similarly, the valuable introduction to the Decapoda by M. F. Glaessner includes a review of their phylogeny.

As might be expected in a compilation of this kind, there are points on which specialists in the various fields might wish to differ with the contributors. This does not, however, detract from the overall value of an important work in a hitherto much neglected field of palaeontological studies. All of the contributors, and in particular the director and editor R. C. Moore (who has in this as in other parts of the treatise taken under his wing the inevitable "orphan" groups which no one wants to own, plus a lengthy "General Features of Crustacea" section in conjunction with L. McCormick), are to be congratulated on the results of their labours.

Palaeontologists, already familiar with the format, excellent standard of production and ample illustration of other parts of the treatise, will need no other comment than that these volumes are among the best so far published (though, it must be added, they are also among the most expensive). Zoologists who will be less familiar with the treatise are urged not to neglect what at first sight of the title might seem to be, for them, barren territory.

H. W. BALL

CIRCULATION STUDIES

General Climatology, 2

Edited by H. Flohn. (World Survey of Climatology, Vol. 2.) Pp. xii + 266. (Elsevier: Amsterdam, London and New York, 1969.) 225*s*.

THIS is one of a series of fifteen volumes, the first three of which, with the title *General Climatology*, are to consist of chapters written by well known specialists. This volume, containing five of these essays, is the first of the three to be published.

In the opening chapter on mechanisms of the general circulation of the troposphere, H. Riehl begins by giving a brief review of the classical model leading to an account of model experiments. He then discusses critically analytical solutions of the high-tropospheric wind field, the mechanism of momentum exchange and of heat and moisture exchange, the kinetic energy generation and maintenance and the general circulation in wave coordinates, concluding with the remark that "understanding of the general circulation will be advanced by choosing the coordinate system most appropriate to the type of circulation studied".

E. L. Deacon, under the title "Physical Processes near the Surface of the Earth", surveys work on microclimates over level uniform terrain and extensive water surfaces. He examines in detail the whole range of surface-atmosphere interactions and includes accounts of the different kinds of fog and of turbulent diffusion of air-borne material.

R. Geiger extends these chiefly microclimatic studies to sloping terrain in a chapter on topoclimates, topoclimatology being defined as the subdivision of general climatology dealing with relationships between land forms and local climates. Beginning with the astronomical theory and examining the effects of screening of the horizon and of clouds, he describes the construction of radiation maps and then the climate of slopes generally. Succeeding sections deal with the climate of valleys, microclimates in mountainous regions, including the climate of caves, and the difficulties of the mapping of topoclimates. He forecasts that "the use of topoclimatic maps will become quite usual in the foreseeable future in the same way as we now use geological maps showing the subsoil or the ground surface for planning purposes".

The editor of this volume, H. Flohn, contributes a chapter on local wind systems, beginning with accounts of examples, followed by the theory, of simple thermally driven circulations, land and sea breezes. Cases of more complicated systems of mountain winds with a diurnal component are then described and analysed theoretically. Lastly, he examines effects on the wind field which are mechanically produced by mountains or escarpments, for example, the generation of the föhn, the bora, the mistral and lee-wave systems.

In the final chapter on climatic fluctuations, H. H. Lamb, after a short summary of the evidence of changes, ice ages and warm epochs, in the remote past, deals in more detail with the main climatic phases of post-glacial time, the past 10,000 years, concluding this section on climatic history with an analysis of observations in the era of meteorological instruments. An account is then given of circulation studies, the preparation of maps of prevailing wind and pressure patterns in different years and epochs, which may reveal the mechanism of climatic changes. The results of the analysis of the author's own series of maps and indices for the period from 1750 and his current work on the extension of the circulation analysis to years before 1750 are described. The chapter ends with a short summary of the causes and course of climatic variation.

This is a very good book which will be valuable to the meteorologist as well as to the climatologist.

JAMES PATON

BOUNDARY LAYERS FOR ENGINEERS

Boundary Layers of Flow and Temperature

By A. Walz. Edited and translated from the German by Hans J. Oser. Pp. xv + 297. (MIT Press: Cambridge, Massachusetts, and London, January 1970.) 164*s*.

BOUNDARY-LAYER theory has formed a major part of fluid dynamics since Prandtl's famous paper was published in 1904. Its first achievement was to resolve the conflict between the hydromechanics of the mathematicians and the hydraulics of the engineers; the former subject was elegant, extensive and founded on a plausible idealization of the behaviour of fluids; the latter was crude, empirical and fragmentary, but much more reliable as a predictor of the actual behaviour of real fluids. Prandtl showed that the small viscosity of these fluids, though negligible in its direct effect over a large part of the domain of flow, could have substantial indirect effects, emanating from the thin layer of fluid adjacent to the solid boundaries of the domain. The subsequent detailed investigations of particular boundary-layer flows completely clarified the qualitative phenomena which arise.

Boundary-layer theory has influenced engineering practice more through the understanding which it promotes than by providing quantitative methods of design; for the differential equations were too difficult to solve exactly until computer methods were devised; and the laws of turbulent transfer, which dominate most practical flows, are only now being discovered. In the past few years, however, fast computational procedures of the finite-difference variety have become available; and satisfactory mathematical models of turbulence have been developed for use with them. Boundary-layer theory is at last ready for use by engineers.

The demonstration of the usability of boundary-layer theory is one of the motives of Professor Walz's book. The material and methods of the book spring, however, from the pre-computer years during and after the Second World War. Thus, from the mathematical point of view, its procedures are approximate rather than rigorous; and the properties of turbulence are incorporated by way of empirically based correlations of the behaviour of complete boundary layers. Though the use of the computer is now advocated for the execution of the calculation methods, the full potentialities of the computer are not exploited.

Although the book is therefore likely to have come rather too late to influence engineering practice widely, its high quality as a piece of exposition deserves recognition. The treatment is scholarly and, granted the basic limitation just mentioned, it is both comprehensive in coverage and fair in evaluation. The author has taken much trouble to ensure that his methods of computation can be understood and practically applied. Engineers will find his methods to be fast, fairly easy to understand, and, within their rather narrow limits of validity, sufficiently accurate.

A few critical remarks should be made, however. The translation from the German is excellent in general, but marred by some inelegancies of construction or diction; thus the choice of the word "clot" for a coherent body of fluid in turbulent motion has led to some comic sentences. More serious is the disregard of the possibility that the solutions of the integral equations, which are Walz's preferred medium of computation, may not be unique; yet this often occurs when the velocity profile is "weighted", in the formation of these equations, by some function of the velocity, u; and it prevents the computation process from being completed. Because "weighting" functions of the cross-stream distance y are free from this disability, the author's preference for u-functions over y-functions may mislead his readers; it can be explained only by the fact that the author has not yet tried to apply his method to problems in which a maximum is present in the $u(y)$ profile, giving rise to two values of y for one of u. Again, Walz recommends von Karman's modifications of the Prandtl–Taylor relation between friction and heat transfer, without mentioning that it brings very little improvement, and is inferior to the more recent formulae of Deissler and others.

In spite of these blemishes, the book remains a valuable contribution to the boundary-layer literature. It was well worth translating.

D. B. SPALDING

PARTICLE TRANSFER

Introduction to the General Theory of Particle Transfer

By V. Kourganoff. (Documents on Modern Physics.) Pp. xiii + 216. (Gordon and Breach: New York and London, January 1970.) $16·80; 140*s*.

THIS book is an attempt to present a graduate student at the beginning of his course with a simple account of the way in which problems in particle transfer can be formulated in terms of differential equations. It provides a meticulous account of the way in which a field of moving particles interacts with a material medium. The mathematical analysis has deliberately been kept simple so as to focus attention on the physical concepts and to allow those who intend to specialize in, say, transport of neutrons to see something of the relationship of their chosen field with that of radiative transfer.

A book of this kind has been needed for some time, but it is not clear that this one properly fills the gap. The level of knowledge assumed is often extremely low—it should hardly be necessary to have to give a proof of Gauss's theorem to graduates—and a good deal of space is occupied by recording minor steps in the argument which the reader might be expected to supply for himself. It is also disappointing that the physics of the microscopic interactions of neutrons and photons with matter is not treated more comprehensively. The mathematical shape of the source and sink terms which determine the complexity of transfer theory depends on these interactions. This book will only give the student a very limited understanding of the relationship of the physics to the more mathematical problems treated in other texts. It is, moreover, extremely expensive for its size, the price being one which few students are likely to want to pay.

Limits and Continuity

By P. P. Korovkin. (Course 1.) Pp. vii + 125. 85*s*.

Differentiation

By P. P. Korovkin. (Course 2.) Pp. vii + 86. 75*s*.

(Pocket Mathematical Library.) Revised English edition; translated and edited by Richard A. Silverman. (Gordon and Breach: New York, London and Paris, May 1969.)

THERE are many texts dealing with school mathematics and introductory university mathematics; but none (in English) with quite the flavour of the present series of seven small books, translated from the Russian. The series consists of two primers, three workbooks and two courses. The primers are concerned with coordinates, functions and graphs, while the workbooks emphasize problems, especially involving sequences, combinatorics and limits. The two course books deal with limits, continuity and differentiation. All books are well written, with illustrations and worked examples, and every enthusiastic mathematics sixth-former may read them for pleasure and profit, and especially in order to be introduced to some of the problem solving encountered at this level in the Soviet Union.

One of the most interesting of the volumes is that entitled *Sequences and Combinatorial Problems*. Here, eighty-nine sample problems are listed and detailed solutions are given. There follows, without solution, a set of thirty-seven test problems. There are some unusual problems relating to arithmetic and geometric progressions, but the combinatorial problems are unfortunately confined to problems of counting. The latter, however, may be due to the difficulty of constructing elementary structural problems of a combinatorial character with simple solutions. The volume entitled *Mathematical Problems: An Anthology* is a gem. It consists of 143 problems, of many different types, with hints and answers, and a set of thirty-five supplementary problems. Some of the problems are tantalizing in their simplicity of statement. It may be of interest to quote two examples:

> Problem 1.—A million lines are drawn in the plane such that no two lines are parallel and at least one other line passes through the point of intersection of each pair of lines. Prove that all the lines are concurrent.
>
> Problem 2.—Three rugs of arbitrary shape, each with an area of 3 square yards, are spread on the floor of a room whose area is 6 square yards. Prove that two rugs overlap and share an area of at least one square yard.

In conclusion, it is worth recording a thought engendered by a reading of the books under consideration. It is clear that in elementary mathematics, as expounded in the Soviet Union, emphasis is still placed overwhelmingly on the classical concepts and sense of values (such as manipulation, but not for its own sake, and problem formulation and solution). It is still respectable to deal with counting problems involving permutations and combinations, and to ask and answer questions which involve an appeal to Euclidean geometry. In fact the biggest single surprise on reading the books is that of finding the degree of emphasis still placed on geometrical thinking. This retention of the "classical" mathematics rather than the wholesale acceptance of the so-called "new" mathematics is a sobering thought, which might well be followed by mathematicians in the western world, especially those concerned with the revision of school mathematics syllabuses.

L. S. GODDARD

QUANTUM MECHANICS

Basic Quantum Mechanics

By J. M. Cassels. (European Physics Series.) Pp. viii + 184. (McGraw-Hill: London and New York, 1970.) 62*s* boards; 42*s* paper.

IT is clear from the preface to this book that Professor Cassels endured all the usual agonies in learning quantum mechanics but was finally so impressed by the elegance and logic of Dirac's presentation that he is determined that his students shall not suffer the same fate. His solution is to present the subject as a set of concepts and rules followed by the logical consequences one may deduce for simple systems, but working throughout at a more elementary level than does Dirac. This seems almost certain to be unpopular with the older generation of physicists accustomed to the concept of the historical approach, but I must come down on the side of the author. If quantum mechanics always seems a difficult subject to teach to physics students, it is surely because the physical picture exists not in terms of classical models but rather in the operator structure, so that the natural starting point must be with the language which works rather than with that which does not.

In general terms the book seems to achieve what was intended, the choice of topics being particularly good, but there remain a number of shortcomings. First, a rather high degree of physical background seems to be required for what is supposed to be a basic text. The reader must be presumed to have been exposed to a fair amount of "the breakdown of classical physics", for no introduction of this type is incorporated. This seems particularly unfortunate, because such experience, insensitively given, could negate the whole concept of this style of presentation. Second, insufficient emphasis seems to have been given to the distinction between the basic quantum techniques and those approximations used in applications, so that there is a danger that students may confuse the two concepts. It is pleasing, however, to see such useful tools presented so early in such a basic course. Finally, there are no problems on which the student may test his comprehension. Experience in teaching this subject convinces me that no student really understands the concepts until he has "got his hands dirty" himself.

Considered as a whole, this is a good book for a first course in non-relativistic quantum mechanics, but it should be adopted only by an experienced teacher who is convinced of the superiority of this method of presentation.

Obituaries

Sir Boris Uvarov

The death of Sir Boris Uvarov, KCMG, DSc, FRS, on March 18, aged 82, has deprived the science of entomology of one of its most eminent men. Best known as a taxonomist—for his description of some 900 new species and 218 new genera, and an ecologist—for his work on the phase theory of locusts, insects and climate, and arid zone entomology, he will also be remembered as the chief founder of international cooperation in locust research and control, and as a pioneer in the biogeographical studies of locusts, forming the scientific basis for the foundation of many international organizations.

Boris Petrovitch Uvarov was born in 1888 at Uralsk in Russia and obtained a first class degree in biology in 1910 at the University of St Petersburg. There followed a period of work in several provincial departments of agriculture and in 1915 at the age of 27 he was made director of the Tiflis Bureau of Plant Protection. He was already an authority on the Orthoptera of Central Asia and had become interested in locusts and their control; in 1919 he was appointed keeper of entomology and zoology in the State Museum and reader in entomology at the University of Georgia, and in 1921 published his famous paper propounding the phase theory of locusts. He was always punctilious in sharing the discovery of locust phases with Fauré, the South African entomologist, but Uvarov's name is universally associated with the theory, not only because he went on to develop it further but because of the practical use he made of it.

The practical opportunity came when he joined the Imperial Bureau of Entomology (now the Commonwealth Institute of Entomology) in London, where he remained from 1920 to 1945; the British government was concerned about locust invasions of the African colonies and Uvarov was the obvious man to consult. He suggested a programme of extensive field surveys in Africa to map the seasonal distribution of locusts, with ecological and biogeographical analysis in London. The results of this work, pursued over several years and interpreted in the light of the phase theory, revealed permanent outbreak areas for both the migratory and the red locust. Uvarov and others had also pointed out that cooperation between the affected countries was utterly essential for locust control, and a series of international conferences was held to promote this view, leading to proposals for international organizations in Africa to control the African migratory and red locusts in their outbreak areas. Progress was interrupted by the 1939–45 war, when the protection of strategic food supplies became vital; Uvarov helped to create the Middle East Anti-Locust Unit on a para-military basis to carry out control campaigns in many countries.

After the war, because of the threat of locusts to overseas agriculture, the Colonial Office set up the Anti-Locust Research Centre as an independent research institute, with Uvarov as director. Uvarov here continued his untiring effort against locusts; the basis of the Centre's work was then, and still remains, the view that efficient locust control is possible only with a background knowledge of the biology, biogeography and behaviour of the species.

The demands of administration had not diminished Uvarov's other interests; he was a world authority on the taxonomy, systematics and biology of Acrididae and in 1928 he had published *Locusts and Grasshoppers*, a lucid review of the whole field. His interest in ecology led to the publication in 1931 of *Insects and Climate*, which stimulated interest in a neglected field.

In the 1940s and 50s Uvarov travelled widely, visiting at least twenty-three countries at the invitation of governments and international organizations and, because of his encyclopaedic knowledge of the subject, he was able to make far-reaching suggestions for locust research and control. The international organizations for controlling the African migratory and red locusts were established and, since then, no plagues of these species have appeared —a striking proof of the validity of Uvarov's theories and their practical significance. Studies of the desert locust, however, showed that its outbreak areas were not restricted; it had an invasion area covering more than fifty countries. Uvarov saw that special coordination was necessary and interested the Food and Agriculture Organization of the United Nations which, in 1953, undertook the international coordination of control campaigns against the desert locust. Uvarov was appointed consultant to the FAO Technical Advisory Committee and was to play a major part, particularly as chairman of the FAO Panel of Experts on the Long-Term Policy for Desert Locust Control in 1956. He also helped to initiate the UNDP/FAO Desert Locust Project, the largest single project ever supported by the UNDP.

In 1959 he retired as director of the ALRC but remained a consultant, and began a new book on grasshoppers and locusts; he was as active as ever and, in 1959, toured Australia at the invitation of the CSIRO to give advice about the Australian plague locust, leading eventually to a large collaborative research project between CSIRO and the ALRC which is still in progress. He had long been a member of the UNESCO Arid Zone Committee and now began to explore a new field, expressed in a series of important papers on arid zone entomology and the entomological problems of agriculture in developing countries. Vol. 1 of *Grasshoppers and Locusts* was published in 1966 and he was working on Vol. 2 until shortly before his death.

Uvarov received many medals, awards and public honours; he was elected to the Royal Society in 1950 and knighted in 1961. He was a man of great strength and integrity of character, coupled with simplicity and humility. Sometimes he had a sharp tongue but it was tempered with a dry sense of humour; above all, he was always ready to help his fellow scientists in any way he could. He would wish nothing better for his memorial than that the work he began and fostered should continue and expand.

Correspondence

Cost of a Facelift

SIR,—The issue of *Nature* of April 25 contains an article about the delay in the resurfacing of the Arecibo reflector which is misleading (*Nature*, **226**, 308; 1970).

The costs of the resurfacing project are neither very uncertain nor have they suddenly risen greatly. The estimated cost has increased in a year from $3·8 million to $4·2 million, giving a percentage increase less than most estimates of the annual inflation in construction costs of this type. The firmness of the $4·2 million figure is supported by a formal fixed price bid at this figure from a competent company.

No significant engineering problems have been uncovered. There is no serious criticism of the proposed type of surface panel and no indication that a heavier surface would be necessary. The engineering of new surface on a foundation whose accuracy is already known is quite straightforward, and the major challenge is actually in determining the least expensive mode of fabrication of the large number of panels.

There is thus no reason for thinking that a much higher price estimate at some future time will arise and that this will require a re-evaluation of radio astronomy priorities. The resurfacing of the Arecibo reflector remains scientifically the most exciting and cost-effective foreseeable improvement to the world's astronomy equipment, and is one of the most promising projects of science in general.

Sincerely yours,

FRANK D. DRAKE

Cornell University,
Arecibo Project Office,
Space Sciences Building,
Ithaca, NY 14850, USA.

It is good to have Professor Drake's assurance, but it remains a fact that the National Science Foundation has undertaken to the Authorization Committee in the Senate that it will not expect to be awarded the money asked for on behalf of Arecibo until a further engineering study has been carried out. Everybody will hope that Professor Drake is right and he after all should know—he has done the work.—Editor, *Nature*.

Abortion Act in Action

SIR,—Your note on the Abortion Act (*Nature*, **225**, 580; 1970) quotes an estimate[1] of 18,000 private legal abortions in 1967, in addition to 10,000 under the National Health Service. Reliable figures for private terminations before the Abortion Act are certainly hard to come by, but there is unequivocal proof that this estimate must be exaggerated.

In 1967, 9,700 (not 10,000) NHS abortions were officially reported for England and Wales[2], so that another 18,000 privately procured would make a total of 27,700 pregnancies legally terminated in that year. But in the first 9·5 weeks under the new Act (April 27–July 2, 1968) 2,752 NHS and 1,660 private legal abortions were notified, corresponding to an annual rate of 24,036. Since it is not to be believed that the coming into operation of a new and more permissive law should have resulted in a significant reduction of the legal abortion rate, and since the NHS total is well established, it is the estimate for private abortions in 1967 which must be too high. Q.E.D.

If the 1967 rate had been the same as for the 9 weeks after April 27, 1968, there would have been no more than 14,356 private legal abortions in that year. But this also seems too high, and it is unlikely that the true figure could have exceeded 10,000, to give a total of 19,700 legal abortions in 1967. This would imply that the 1967 rate had been 18 per cent below what it was immediately after the new Act came into force, which is not excessive when compared with the 32 per cent increase in the next quarter (7,938 in the 13 weeks July 3–October 1), and a further 25 per cent (9,907 legal abortions) for the quarter ended December 31, 1968[3].

Your note also says that while there had been between 45 and 50 deaths from abortion each year for the past 20 or so years, this had dropped to 22 during 1969. But that is not so, since the figure of 22 was only for the 10 months ended October 31, 1969[4]. Mr Richard Crossman (Minister of State for the Social Services) has recently given[5] the provisional total for the full year 1969 as 29 deaths due directly to abortion, including 4 resulting from legally induced abortion (ICD 640 and 641), but not including a further 13 deaths after legal terminations of pregnancy under the Act which were not classified as directly due to abortion.

It may well be true that abortion deaths have averaged 45–50 over the past 20 years, but the rate is known to have been falling during this period, and for 1967, which was the last full year under the old law, the Registrar General[3] recorded 34 abortion deaths:

Abortion induced for medical indications (640)	1
Abortion induced for other legal indications (641)	0
Abortion induced for other [illegal] reasons (642)	17
Spontaneous abortion (643)	4
Abortion not specified as induced or spontaneous (644)	11
Other abortion (645)	1
Total abortion deaths	34

Even assuming that none of the 13 deaths following upon but not classified as directly due to legal abortions in 1969 would formerly have been counted as abortion deaths, and it is not entirely clear whether this would have been so, the improvement has been only from 34 deaths in 1967 to 29 in 1969. Perhaps 1967 may have been a better year than average, but your note in concluding that "The Act has been remarkably successful in reducing the death rate from abortion. The latest figures from the Ministry of Health show that in England and Wales the number of deaths from abortion, which has been between 45 and 50 per year for the past twenty or so years, dropped to 22 during 1969", does perhaps rather overstate the case.

Yours etc.,

C. B. GOODHART

Gonville and Caius College,
Cambridge.

Announcements

University News

Dr R. W. Hockney, IBM Research Center, New York, has been appointed professor of computer science in the **University of Reading.**

In the **University of Sheffield, Dr D. A. Walker,** Imperial College, has been appointed professor of biology in the Department of Botany, and **Mr J. A. Thornton** has been appointed professor and head of the Department of Anaesthetics.

Mr Andrew Colin, University of Lancaster, has been appointed professor and head of the Department of Computer Science in the **University of Strathclyde,** and **Mr James G. Fraser** has been made director of computer services.

Dr J. E. Smith has been appointed to the new chair in microbiology in the Department of Biological Sciences, **University of Surrey.**

Appointments

Mr Philip Homan has been appointed to the post of director of the **Ministry of Technology's Office for Scotland** in Glasgow.

Mr N. S. Liverman, director of Normans Nurseries Ltd, has been appointed chairman of the governing body of the **Glasshouse Crops Research Institute,** in succession to the late Mr L. C. Madsen.

Miscellaneous

Lieutenant-Colonel F. J. Griffin has been awarded the **International Medal** of the Society of Chemical Industry. **Dr Charles Stark Draper,** Massachusetts Institute of Technology, has been awarded the **Founders Medal** of the US National Academy of Engineering.

Dr Donald J. LeRoy, National Research Council of Canada, has been awarded the **Chemical Institute of Canada Medal** for 1970.

The international journal *Organic Mass Spectrometry* has issued a **cumulative index of 2,200 chemical compounds** with special reference to those for which bar graphs or tabulator data have been published. The index is available free from Heyden and Son Ltd, Spectrum House, Alderton Crescent, London NW4.

Professor E. V. Shpol'skii has written to say that the English edition of his book *Atomic Physics* reviewed in *Nature* (**224**, 1135; 1970) was an incomplete translation of his Russian work. In the English edition it was not mentioned that the translation is of volume 1 only of the two-volume Russian edition. There is a German translation of the complete work available: *Atomphysik*, Teil 1 and Teil 2 (VEB Deutscher Verlag der Wissenschaften: Berlin, 1970).

The following elections have been announced by the **US National Academy of Sciences**: *Foreign Secretary,* Professor Harrison Brown, California Institute of Technology; *Members of the Council,* Dr Kingsley Davis, University of California, Professor James V. Neel, University of Michigan, Professor James A. Shannon, Rockefeller University, Professor Robert L. Sinsheimer, California Institute of Technology, Professor Clement L. Markert, Yale University; *Members,* Professor R. M. Adams, Dr B. J. Alder, Professor J. D. Baldeschwieler, Professor J. A. Berson, Professor P. D. Boyer, Dr L. M. Branscomb, Professor B. F. Burke, Professor S. A. Cain, Professor R. B. Corey, Professor J. W. Cronin, Professor W. G. Dauben, Dr E. E. David, Professor R. Emerson, Professor S. H. Emerson, Professor A. E. J. Engel, Professor R. A. Good, Professor R. M. Goody, Professor H. Grad, Professor J. D. Hardy, Professor L. A. Heppel, Professor H. Hotelling, Professor A. D. Kaiser, Professor N. O. Kaplan, Professor I. M. Klotz, Professor R. C. Lancefield, W. B. Langbein, Professor P. D. Lax, Professor D. S. Lehrman, Dr A. S. Leopold, Professor C. Levinthal, Professor M. S. Livingston, Professor W. J. Luyten, Professor R. A. Marcus, Professor C. V. Moore, Professor E. P. Odum, Dr R. Patrick, Professor G. L. Pearson, Professor A. Rich, Professor H. L. Roman, Professor P. A. Samuelson, Professor A. L. Schawlow, Professor M. M. Schiffer, Professor S. Smale, Dr G. D. Snell, Professor J. L. Strominger, Professor M. Tinkham, Professor B. J. Underwood, Professor B. Wallace, Professor A. White, Professor A. S. Wightman.

International Meetings

May 29, **The Use of CS and Other Harassing Gases in War: the Geneva Protocol Then and Now,** London (Professor P. J. Lindop, Department of Radiobiology, St Bartholomew's Hospital Medical College, Charterhouse Square, London EC1).

September 14–16, **Plastics Pipes,** Southampton (Symposium on Plastics Pipes, c/o Dr Howard Allen, Department of Civil Engineering, The University, Southampton SO9 5NH).

September 23–25, **Sporopollenin,** London (Symposium Organizing Secretaries, Department of Geology, Royal School of Mines, Imperial College, London SW7).

October 15–16, **Telecommunication,** Madison (TDAL and ETN/SCA Conference, Mrs Anne G. Niles, Department of Nursing, University Extension, 606 State Street, Madison, Wisconsin 53706, USA).

October 26–28, **Electronic and Aerospace Systems,** Washington (Technical Conference Services, IEEE Headquarters, 345 East 47th Street, New York, NY 10017, USA).

October 29–30, **Chemisorption and Catalysis,** London (Conference Secretary, Institute of Petroleum, 61 New Cavendish Street, London W1).

November 2–4, **Ceramic Machining and Finishing,** Gaithersburg, Maryland (NBS Office of Technical Information and Publications, Room A500/101, Washington, DC 20234, USA).

November 4–6, **Nuclear Science,** New York (Institute of Electrical and Electronics Engineers, 345 East 47th Street, New York, NY 10017, USA).

November 6–10, **First National Biological Congress,** Detroit (Dr M. Ben, American Institute of Biological Sciences, 3900 Wisconsin Avenue NW, Washington DC 20016, USA).

November 9–16, **Vision Week** at Ohio State, Columbus (Dr Glenn A. Fry, College of Optometry, Ohio State University, 338 West Tenth Avenue, Columbus, Ohio 43210, USA).

November 15–19, **Joint Meeting of the American Nuclear Society and the Atomic Industrial Forum and Atomic Fair,** Washington (Mr O. J. Du Temple, American Nuclear Society, 244 East Ogden Avenue, Hinsdale, Illinois 60521, USA).

November 17–20, **Magnetism and Magnetic Materials,** Miami Beach (G. P. Rodrique, Local Committee, Georgia Institute of Technology, School of Electrical Engineering, Atlanta, Georgia 30332, USA).

November 30–December 4, **Engineering Materials and Design,** London (c/o Industrial and Trade Fairs, Ltd, Commonwealth House, New Oxford Street, London WC1).

December 1–8, **Results of Research on Representative and Experimental Basins,** Wellington (Mr G. W. Markham, Royal Society of New Zealand, PO Box 196, Wellington, New Zealand).

December 6–11, **International Clean Air Congress,** Washington (Mr Arnold Arch, Executive Secretary, Air Pollution Control Association, 4400 Fifth Avenue, Pittsburgh, Pennsylvania 15213, USA).

December 14–18, **Relativistic Astrophysics,** Austin (L. C. Shepley, Physics Department, University of Texas, Austin, Texas 78712, USA).

Sabbatical Itinerants

In the hope of providing some practical assistance in the good cause of mobility between laboratories, *Nature* advertises the needs for housing of families about to take up periods of sabbatical leave. To begin with, no charge will be made for advertisements like this. It is hoped that a period of experiment will show what form these advertisements could most usefully take and whether they are effective.

Vacant: Furnished house in Chevy Chase, Maryland, close to NIH and most Washington and suburban Maryland hospitals and universities (American, George Washington, Howard, Catholic, and Georgetown). Three bedrooms, near elementary school, bus, shops, public park. One year lease, available June 15, 1970, $300 the month. Please contact Dr L. Lewin, 8218 Larry Place, Chevy Chase, Maryland 20015, USA (telephone 301–588–0982).

Wanted: Three-bedroomed, furnished house in Reading, Berkshire, for American professor, wife, 4 children. Prefer central heating. Will consider one year lease mid-August 1970 to mid-August 1971, up to £90 per month. Please contact L. Sequeira, Department of Plant Pathology, University of Wisconsin, Madison, Wisconsin 53705, USA.

Wanted: Furnished 3 or preferably 4-bedroom house with central heating, in Reading, Berkshire, for year beginning August 20, 1970. Please contact Dr Locke White, jun., Department of Physics, Davidson College, Davidson, NC 28036, USA.

British Diary

Monday, May 18

Avalanche Diodes—Normal and Subnormal (11 a.m. colloquium) Institution of Electrical Engineers, at Savoy Place, London WC2.

Studies on the Mechanism of Malarial Immunity (5 p.m.) Professor S. Cohen, University of London, at the Wright-Fleming Institute, St. Mary's Hospital Medical School, Norfolk Place, London W2.

The Effects of Metrication on Power Cable Specifications (5.30 p.m. discussion meeting) Institution of Electrical Engineers, at Savoy Place, London WC2.

The Global Challenge (5.30 p.m.) Mr Thane Rhiney (Rome), University of London, in the Botany Theatre, University College London, Gower Street, London WC1. (First of three Special University Lectures in Conservation.)

Tuesday, May 19

Aeronautical Acoustics as a Problem in Applied Mathematics (5.30 p.m.) Professor J. E. Ffowcs Williams, University of London, at Imperial College of Science and Technology, London SW7. (Inaugural Lecture.)

British Postal Engineering Conference (three days) Institution of Mechanical Engineers, Manipulative and Mechanical Handling Machinery Group, at 1 Birdcage Walk, London SW1.

Charles Darwin and his Circle (5 p.m.) Professor Sir Hedley Atkins, University of London, at the Middlesex Hospital Medical School, Mortimer Street, London W1.

Excavations in Baba Jan, Luristan 1966–1969 (5.45 p.m.) Dr Clare Goff, University of London, at the Institute of Archaeology, 31–34 Gordon Square, London WC1.

Fluorescence with reference to Medical and Pharmaceutical Applications (4.30 p.m.) Mr J. W. Bridges, Society for Analytical Chemistry, jointly with Loughborough University of Technology Chemical Society, at the University of Technology.

Repetitive Activity in Nerve and Muscle (5.30 p.m.) Professor R. Stampfli (Saar), University of London, in the Physiology Theatre, University College London, Gower Street, London WC1.

Signal Processing Methods for Radio Telephony (three-day conference) Institution of Electrical Engineers, at Savoy Place, London WC2.

Wednesday, May 20

Against Nature : The Use and Misuse of Birth Control (5.15 p.m.) Dr D. M. Potts, Institute of Biology with the support of the Eugenics Society, in the Lecture Hall, Natural History Museum, Cromwell Road, London, SW7. (Tenth Darwin Lecture.)

Air Traffic and Navigation, Institute of Navigation, and the Royal Aeronautical Society, at 4 Hamilton Place, London W1.

Meteorology and Conservation (5 p.m. discussion meeting) Royal Meteorological Society, at 49 Cromwell Road, London SW7.

Numerical Computation of Aeronautical Structures by Finite Element Methods I (6 p.m.) Professor B. Fraeijs de Veubeke (Liège), University of London, at Imperial College of Science and Technology, London SW7. (First of four Special University Lectures in Aeronautical Engineering. Further lectures on May 21, 26 and 28.)

Research and Conservation (an Identification of Major Problems to be Solved) (5.30 p.m.) Mr Thane Rhiney, University of London, in the Botany Theatre, University College London, Gower Street, London WC1.

Sonic Environmental Testing of Components and Equipments (6 p.m.) Mr D. Chadwick, Institution of Electronic and Radio Engineers, Instrumentation and Control Group, at 9 Bedford Square, London WC1.

The Psychiatry of Vagrancy (5.30 p.m.) Dr A. D. Isaacs, University of London, at the Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5.

Thursday, May 21

Arbovirus Epidemiology Associated with Established and Developing Rice Culture (7.30 p.m. symposium) Royal Society of Tropical Medicine and Hygiene, at 26 Portland Place, London W1.

Celestial Physics Laboratories (5.30 p.m.) Professor Sir Martin Ryle, FRS, University of London, at Senate House, London WC1. (John Coffin Memorial Lecture in Science.)

Profiting from Experience (a Demonstration of the Case Method as an Educational Tool) (5.30 p.m.) Mr Thane Rhiney, University of London, in the Botany Theatre, University College London, Gower Street, London WC1.

Subcellular and Macromolecular Aspects of Synaptic Transmission (two-day discussion meeting) Royal Society, at 6 Carlton House Terrace, London SW1.

The Human Factors in Management (5.30 p.m. discussion) Institution of Electrical Engineers, at Savoy Place, London WC2.

Friday, May 22

Research in Progress (10 a.m.) Department of Surgery, Royal Postgraduate Medical School, DuCane Road, London W12.

APPOINTMENTS VACANT

NEW ZEALAND DEPARTMENT OF AGRICULTURE

The Animal Health Division is seeking recruits to its Veterinary Advisory Officer Service. Positions are available in various localities in New Zealand with headquarters in the larger provincial towns.

Positions are available specialising in infertility brucellosis; infectious diseases (2); metabolic disease; mastitis; and as Veterinary Advisory Officers (General). Appointments may be to the permanent staff or on a four-year contract basis.

Duties: Duties are broadly similar to those of Veterinary Investigation Officers in the United Kingdom. They include liaison with, and special services to practising veterinarians ; field investigation and surveys of disease incidence; development of disease control and eradication programmes; development of educational programmes for farmers on disease prevention ; field examination of new therapeutic products such as vaccines.

Qualifications: Minimum qualification M.R.C.V.S. or Degree in Veterinary Science. Preference will be given to those with post-graduate qualifications and previous field investigation experience and experience in epidemiology of exotic diseases. However, younger veterinarians with appropriate field experience who seek a career in the field of preventive veterinary medicine will be considered for appointment as Assistant Veterinary Advisory Officers. Developing Officers are given the opportunity for appropriate postgraduate training and training overseas in the recognition and control of exotic animal diseases.

Salary: Salaries for Veterinary Advisory Officers are in the range $NZ4,013 per annum to $NZ7,463 per annum. There are opportunities for advancement in administrative positions beyond this. For Assistant Veterinary Advisory Officers the salaries range from $NZ4,013 to $NZ5,248 per annum, advancing in due course through the Veterinary Advisory Officer scale. Starting salary in each case will depend on experience since graduation and relevant qualifications.

Expenses: Fares for appointee, wife and fully dependent children, including return fares for four-year contract appointees.

Interview, medical and passport expenses for appointee are payable by the Department.

A reasonable allowance is given for bringing light luggage to New Zealand, and assistance is given for furniture storage in United Kingdom (up to $NZ400) for contract employees.

Housing assistance is available to contract appointees.

Application forms and general information are available from the High Commissioner for New Zealand, New Zealand House, Haymarket, London, S.W.1, with whom applications will close on June 17, 1970.

Please quote reference B 13/2/170/1809 when inquiring. (1921)

NYEGAARD & CO. A/S
Pharmaceuticals and Technical Products

A vacancy exists for a

PHARMACOLOGIST

in our research department, where a small but enthusiastic staff of chemists, biochemists, pharmacologists etc. are tackling challenging problems in the pharmaceutical field. Our principal research interests at present are in the X-ray contrast and biochemical reagent fields.

Applicants should have a degree in pharmacology or related subject and some research experience: a higher degree would be no disadvantage.

Ability to speak Norwegian is not anticipated.

We can offer a good salary, an encouraging working atmosphere, 4 weeks holiday, national health and pension schemes and Norway's unequalled opportunities for outdoor life.

Applications as soon as possible to

Personell Department
Nyegaard & Co. A/S
Postboks 4220
Oslo, Norway.

NYEGAARD & CO·AS·OSLO

Nyco

(1955)

CHEMIST/BIOCHEMIST

The Ministry of Defence requires a Chemist/Biochemist (graded Senior Scientific Officer/Scientific Officer) to join a group at the Microbiological Research Establishment, Porton, Wiltshire, whose principal function is to provide microbiol products for a wide range of research applications. The successful candidate will be expected to give leadership in the areas of extraction chemistry and analytical chemistry, especially in relation to enzymes. He will be encouraged to extend his interests to cover the full range of disciplines involved in the development of microbiol products. Publication of results is also encouraged.

Qualifications and Experience: Candidates should have a 1st or 2nd Class Honours degree, or equivalent in either biochemistry, microbiology or an appropriate related subject and for SSO at least three years' relevant post-graduate research experience. Knowledge and experience in protein chemistry, but especially in methods for the purification and assay of enzymes would be useful.

Superannuation under FSSU. Prospects of promotion and permanent pensionable employment.

Age: SO under 29; SSO normally 26–31.

Salary: SO £1,162–£1,982; SSO £2,193–£2,703.

APPLICATION FORMS from Mr. A. L. LYTTON, Ministry of Defence CE2(E)(AD) Room 302, Northumberland House, Northumberland Avenue, London WC2.

(1960)

ANALYTICAL RESEARCH

The Research Division of Pfizer Limited was created in 1957 and since that time has expanded steadily and now employs some 450 people, 200 of whom are scientists in various disciplines: chemistry, biochemistry, pathology, pharmacology, bacteriology, virology, parasitology, veterinary science and medicine. Its direct research expenditure is over £1.7 million in 1970.

We have a vacancy for a chemist in our Chemical Research Department whose main responsibility will be the design and development of appropriate analytical methods in the investigation of new research syntheses for novel compounds, and their subsequent preparation for new drug submissions to regulatory authorities.

The successful applicant will have a Ph.D. in analytical/physical organic chemistry, or be a graduate with not less than 3 years relevant experience. A good knowledge of organic chemistry and an ability to understand synthetic problems from the analytical viewpoint is essential. He should also have a reasonable knowledge of techniques such as GLC, TLC, UV, IR, NMR, Mass Spectrometry as applied to Organic Chemistry in general.

He will liaise closely with a large number of research staff in a team for attainment of research objectives of the Company. Attendance at scientific meetings and the publication of papers is encouraged.

The laboratories, modern and well-equipped, are situated on the Kent coast at Sandwich. There is a wide choice of residence in pleasant coastal or rural areas.

The starting salary will be competitive and the conditions of employment include pension and death benefit scheme, bonus scheme and the payment of removal expenses, if appropriate.

Applications, which will be treated in the strictest confidence should be addressed to:

D. W. Sells,
Personnel Manager,
Research Division,
Pfizer Limited,
Sandwich, Kent.

(1993)

CITRUS ENTOMOLOGIST

SWAZILAND

The Swaziland Citrus Board invites applications for the post of citrus entomologist, to continue research on the biology and control of the major pests of citrus in Swaziland. The citrus research unit is based at the central research station of the Department of Agriculture at Malkerns.

Applicants should have a B.Sc. in zoology or entomology with some postgraduate research experience in agricultural entomology.

Salary according to qualifications and experience in the range R3,200 to R4,500, or higher in exceptional cases. £1 sterling = R1.71. The initial contract is for 3 years, with gratuity of 25% on completion of contract, which may be renewed for further terms of 3 years. Fares paid for appointee and dependants. Modern house at sub-economic rental. Free ordinary medical attention is provided for appointee and family.

Applications giving details of education and experience, with the names of two referees, should be sent to:

The Secretary, Swaziland Citrus Board, P.O. Box 343, Mbabane, Swaziland, as soon as possible.

(1828)

NORTH EAST LONDON POLYTECHNIC

ROMFORD ROAD, STRATFORD, E.15

DEPARTMENT OF POSTGRADUATE MOLECULAR BIOLOGY

Applications are invited for appointments as LECTURER/SENIOR LECTURER within this newly established Department. There are five vacancies in the particular fields detailed below:

Molecular Biology
Biochemical Genetics
  Preferably concerned with nucleic acid and protein biosynthesis.
Cell Biology
  with special reference to tissue culture.
Protein Biochemistry
  fractionation and identification.
Cellular or Genetic Immunology

Although candidates with research interests in these fields are preferred, others will be considered. All appointees will be expected to participate in research within the Department and in organising and teaching in the Postgraduate courses. Good research facilities are available.

Salary Scale:
  Lecturer Grade I, £1,315 to £2,285 per annum.
  Lecturer Grade II, £2,032 to £2,622 per annum.
  Senior Lecturer, £2,622 to £2,957 per annum.
  (including London Allowance).

Details and Application form from R. P. Hornung, Chief Administrative Officer, North-East London Polytechnic, Romford Road, London, E.15. (1932)

UNIVERSITY OF LONDON KING'S COLLEGE

DEPARTMENT OF CHEMISTRY

Applications are invited for two POSTGRADUATE awards (S.R.C. rates plus fees) for research in the field of organophosphorus chemistry. Candidates would be expected to register for the degree of Ph.D. (University of London) and should have, or expect to have, a good B.Sc. degree or equivalent qualifications. The Department is fully equipped with modern instruments (including n.m.r. and e.s.r.) and attendance at postgraduate summer courses would be supported and encouraged.

Applications (including curriculum vitae and the names of two referees), should be sent, as soon as possible, to Dr. C. D. Hall (c/o Professor D. H. Hey, F.R.S.), Department of Chemistry, King's College London, Strand, London, WC2R 2LS.

(1934)

UNIVERSITY OF SOUTHAMPTON

INSTITUTE OF SOUND AND VIBRATION RESEARCH

LECTURESHIP IN STRUCTURAL DYNAMICS

Applications are invited for the post of Lecturer in the Institute of Sound and Vibration Research. Applicants should have experience and research interests in the field of structural dynamics. The person appointed will be expected to assist in the undergraduate and postgraduate teaching in the Institute and also to develop research work in one or more aspects of structural dynamics. Salary scale: £1,585 to £2,850 with a merit bar at £2,045.

Further particulars may be obtained from the Deputy Secretary, The University, Southampton SO9 5NH, to whom applications (seven copies from United Kingdom applicants) should be sent by not later than May 30, 1970, quoting ref.: N. (1922)

UNITED NATIONS

seeks

Science Affairs Officer

Applications invited from persons with scientific background, for appointment to the Office for Science and Technology. Duties include preparation of reports on various aspects of the application of science and technology to problems of economic and social committees. The work of the office is closely associated with that of the United Nations specialized agencies and IAEA as well as with other inter-governmental and non-governmental organizations.

High university degrees desired in such fields as human biology, nutrition, computer technology and applications, environmental and oceanographic sciences, nuclear energy and engineering research, some background in the social sciences (preferably economics) and an interest in and familiarity with the conditions and problems of developing countries. Capacity to write clear English in relatively non-technical terms highly essential; additional knowledge of French highly desirable.

Starting Salary is in range of $13,980–$17,140 plus substantial cost-of-living adjustment. Benefits include six weeks paid vacation per year; medical and dental insurance and a pension plan.

Address replies to:

Secretariat Recruitment Service,

United Nations, New York, N.Y. 10017

(2031)

ELECTRON MICROSCOPE TECHNICIAN

A Senior Technician or Technician is required to assist in work on the physical biochemistry of muscle proteins. Electron microscopy forms a large part of the work, and some experience in this technique is essential. Salary on the scale (currently under review): Technician Minimum: £743, Maximum: £1,127 per annum. Senior Technician Minimum: £1,126, Maximum: £1,361 per annum.

Application to Dr. A. J. Rowe, School of Biological Sciences, University of Leicester, Leicester. (1964)

UNIVERSITY OF MANCHESTER

DEPARTMENT OF CHILD HEALTH

RESEARCH ASSISTANT required to join newly-formed group studying hormonal control of foetal growth. Zoological, physiological or biochemical background to II 1 or I class honours degree desirable. Study for a higher degree encouraged. Salary up to £1,355 per annum. Duties begin July 1, period of appointment to be negotiated.

Particulars and application forms (returnable by May 30) from the Registrar, The University, Manchester, M13 9PL. Quote ref. 102/70/Na. (1979)

UNIVERSITY OF IBADAN

NIGERIA

Applications are invited for (a) SENIOR LECTURESHIPS, (b) LECTURESHIPS IN DEPARTMENT OF PHYSICS. Appointments will be made at the Senior Lecturer level where possible, and preference will be given to applicants with research experience in the fields of ionospheric physics, geomagnetism, applied geophysics, or the physics of the lower atmosphere. Salary scales: (a) £N2,275 to £N2,575 per annum. (b) £N1,200 to £N2,175 per annum. (£N1 = £1 3s. 4d. sterling). Salary supplemented in range £450 to £725 per annum (sterling) and education allowances and children's holiday visit passages payable in appropriate cases by British Government. F.S.S.U. Family passages; various allowances; regular overseas leave.

Detailed applications (six copies), naming three referees, by June 26, 1970, to Inter-University Council, 90/91 Tottenham Court Road, London, W1P ODT, from whom particulars are available. (2021)

UNIVERSITY OF DUBLIN
Trinity College

School of Veterinary Medicine

CHAIR OF CLINICAL VETERINARY PRACTICES

Applications are invited for the above post, which will fall vacant in October, 1970. The Professor in Clinical Veterinary Practices is head of the department embracing Veterinary Medicine, Veterinary Surgery, Veterinary Obstetrics and Reproductive Diseases, Animal Husbandry and related disciplines. Further information may be obtained from the:

Secretary to the College,
Trinity College,
Dublin 2.

Closing date for the receipt of formal applications is June 13, 1970. (2015)

UNIVERSITY OF LONDON

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

COURTAULD INSTITUTE OF BIOCHEMISTRY

A graduate Biochemist is needed to undertake a study of the Biosynthesis of Plasma Lipoproteins of the role of the Liver in maintaining plasma lipoprotein patterns. The appointment, initially for three years, will provide opportunities for study for a higher degree. Salary, subject to review, within the scale £860 to £1,010 and superannuation under the F.S.S.U.

Applications to Dr. Mills, Courtauld Institute, The Middlesex Hospital Medical School, London, W1P 5PR. (1965)

UNIVERSITY OF STRATHCLYDE

Department of Economic History

LECTURESHIP IN HISTORY

Applications are invited from suitably qualified candidates for the above post. Candidates should have special competence in the field of late mediaeval and early modern European History.

Salary scale: £1,355 to £3,105 per annum, with F.S.S.U. Placing on scale according to qualifications and experience.

Application forms and further particulars (quoting 28/70) can be obtained from the Registrar, University of Strathclyde, George Street, Glasgow, C.I, with whom applications should be lodged by May 29, 1970.

(2016)

UNIVERSITY OF SHEFFIELD

DEPARTMENT OF PHYSICS

Applications are invited for the post of RESEARCH ASSISTANT to Professor N. H. March, tenable for two years in the first instance and supported by a Science Research Council Grant. Work will be on phonon theory in liquids and solids. Commencing salary in the range £1,240 to £1,815, dependent on qualifications and experience. Applicants should have a Ph.D. or equivalent research qualifications in Theoretical Physics.

Applications to the Registrar by June 8, 1970. Quote Ref.: R.39/G. (1991)

The Polytechnic of the South Bank

(Proposed)

FACULTY OF ENVIRONMENTAL SCIENCE & TECHNOLOGY

The Faculty is concerned with the scientific specification, design and engineering of the environment for man, his food and his industry. This involves the closest collaboration between scientists, engineers, architects, public health officials, industrial medical officers and managers. The Faculty will continue the teaching and research work of the National College for Heating, Ventilating, Refrigeration and Fan Engineering in this developing field—new degree and postgraduate courses are also being planned.

It is intended to fill the following new posts in September 1970:

PRINCIPAL or SENIOR LECTURERS in

Environmental Technology of Buildings (N.1)
(with special interest in the Total Energy Concept in the design of building services)
Environmental Physics (Heat Transfer) (N.2)
Environmental Physics (Acoustics) (N.3)
(Two Principal Lectureships are available to candidates with appropriate experience and qualifications)

SENIOR LECTURERS in

Applied Heat Transfer (Buildings) (N.4)
Heating and Ventilating Contracting (including Air Conditioning) (N.5)
Heating Plant (Buildings) (N.6)
Environmental Pollution (N.7)

LECTURER (Grade II) in

Refrigeration Plant and Applications (N.8)

Salary Scales (plus in each case £120 p.a. recently approved by the Burnham Education Committee)

Principal Lecturer—£2,767–£3,107
Senior Lecturer—£2,502–£2,837 Lecturer II—£1,912–£2,502

RESEARCH ASSISTANTS are also required for work on—

(a) the operational characteristics of air conditioning systems;
(b) the turbulent mixing of air;
(c) the interaction of ventilation and noise in air conditioned offices.

Further details and application forms, quoting reference, from The Clerk to the Governing Body (Room 407), Borough Polytechnic, Borough Road, London S.E.1. (Closing date 29 May, 1970.) (1985)

CANADA

GOVERNMENT OF SASKATCHEWAN

PRECAMBRIAN GEOLOGISTS (M.Sc. or Ph.D.) to lead five man summer field parties in geological mapping in the Precambrian Shield area of Saskatchewan and after laboratory studies to prepare reports for publication.

SEDIMENTARY GEOLOGIST (Honours Degree or Degree in Geological Engineering) to pick formation boundaries from mechanical logs, examine cores and samples and prepare maps, cross-sections and reports for publication.

GEOPHYSICIST (Graduate in Geophysics or equivalent) for checking incoming data, inspecting field operations, organizing studies for departmental use and publication and reviewing regulations. Qualifications must include professional experience in exploration work with emphasis on interpretation.

Satisfactory commencing salaries will be paid depending upon experience and training.

Please contact Mr. W. C. A. Knights, Immigration Department, Government of Saskatchewan, 28 Chester Street, London, S.W.1 (01-235-1871). (1980)

UNIVERSITY OF DUNDEE

Applications are invited for the post of RESEARCH FELLOW in the DEPARTMENT OF BIOLOGICAL SCIENCES from August 1, 1970, or as soon as possible thereafter. The successful candidate, who is expected to have a higher degree involving entomology, will work under the direction of Dr. F. L. Waterhouse, in stored products entomology with particular reference to insect behaviour. The appointment will be for one year in the first instance. Salary in the region of £1,470 per annum.

Applications (three copies), containing the names of two referees, should be sent by May 30, 1970, to The Secretary, The University, Dundee DD1 4HN. (1881)

THE BRITISH COUNCIL

BRAZIL

THE TECHNICAL INSTITUTE OF AERONAUTICS, SAO JOSE DOS CAMPOS, SAO PAULO requires TWO PROFESSORS / ASSOCIATE PROFESSORS specialising in (a) INTERNAL COMBUSTION AND GAS TURBINE ENGINEERING and (b) THERMAL POWER PLANTS by July, 1970, or as soon after as possible. Candidates should have a degree from a university in Britain and (for post (a)) experience in Engine Combustion problems or hydrocarbon combustion in general, and (for post (b)) experience of research in flow problems in engines or of engineering applications of compressible flow problems. For both posts a Ph.D. degree, and some knowledge of Portuguese would be an advantage.

Salary: £2,850 to £3,750 per annum according to qualifications and experience. Married oversea allowances within the following ranges: accompanied £591 to £320, unaccompanied £406 to £135. Children's and home education allowances. Income tax refunded if levied. Free furnished accommodation. Outfit grant. Employer's superannuation contribution paid. Medical and insurance schemes. Fares paid for Professor and family, including mid-tour passages for children in Britain. Assistance with freight on approved car. Two-year contract guaranteed by the British Council. 70/OU80-81.

THE TECHNICAL INSTITUTE OF AERONAUTICS, SAO JOSE DOS CAMPOS, SAO PAULO requires a VISITING PROFESSOR OF TELECOMMUNICATIONS by July, 1970, or as soon after as possible. Candidates, preferably men, should have a degree from a University in Britain, a postgraduate qualification, and professional and teaching experience. Some industrial experience would be an advantage.

Salary: £2,850 to £3,750 per annum according to qualifications and experience. Married overseas allowances within the following ranges: accompanied £591 to £320, unaccompanied £406 to £135. Children's and home education allowances. Income tax refunded if levied. Free furnished accommodation. Outfit grant. Employer's superannuation contribution paid. Medical and insurance schemes. Fares paid for Professor and family, including mid-tour passages for children in Britain. Assistance with freight on approved car. Two-year contract guaranteed by the British Council. 70/OU79.

Write, quoting relevant reference number, to Appointments Division, The British Council, 65 Davies Street, London W1Y 2AA, for further particulars and application form to be returned completed as soon as possible. (1914)

EDITORIAL ASSISTANT REQUIRED TO edit and prepare for printing manuscripts dealing with the science and technology of metals and alloys, to correct printers' proofs, and to deal with routine editorial matters. Knowledge of English usage and of scientific or technical terminology essential, metallurgical background desirable. Salary not less than £1,250 per annum.—Apply in writing to the Institute of Metals, 17 Belgrave Square, London, S.W.1. (2007)

Nature in North America: The *Nature* office in Washington DC has opened and contributors in the United States and Canada are invited to submit manuscripts for publication either to the address given below or to the present London office. The intention is that each office will be able to answer inquiries about all manuscripts and other matters. This is one of several steps by which it is hoped to provide a better service for readers and contributors.

We made a successful atomic absorption spectrophotometer –then we made it even better

And that's exactly what Pye Unicam did with the world-famous Unicam SP90 Atomic Absorption Spectrophotometer. It's now the Unicam SP90 Series 2, but it's not just the name that has changed. Absorbance or energy scales can now be presented in linear form on the integral meter or on a pen recorder, with continuous scale expansion of up to 10x for absorbance. Results can also now be shown on a digital display and printout accessory. The sensitivity specification has been increased as a result of improved hollow cathode lamps and excellent optical quality, whilst still preserving the outstanding detection limits. And, of course, there are all the first-class features and accessories associated with the original SP90 spectrophotometer–like flame emission facilities, a wide choice of flame and burner systems (including nitrous oxide with a new burner head), a three-lamp turret and automatic sampling. For more information and full technical details on this new instrument and the range of hollow cathode lamps, write to Pye Unicam Ltd.

Son of a gun.

The son: our new 1 ml Biopette automatic pipette. And the gun it's a son of: our original revolver-reminiscent Biopette. So the chore of repetitive pipetting is now further lessened.

THE NEW 1 ML BIOPETTE

The charm of this new automatic pipette is that it retains the advantages of the original Biopette while picking up a few of its own.

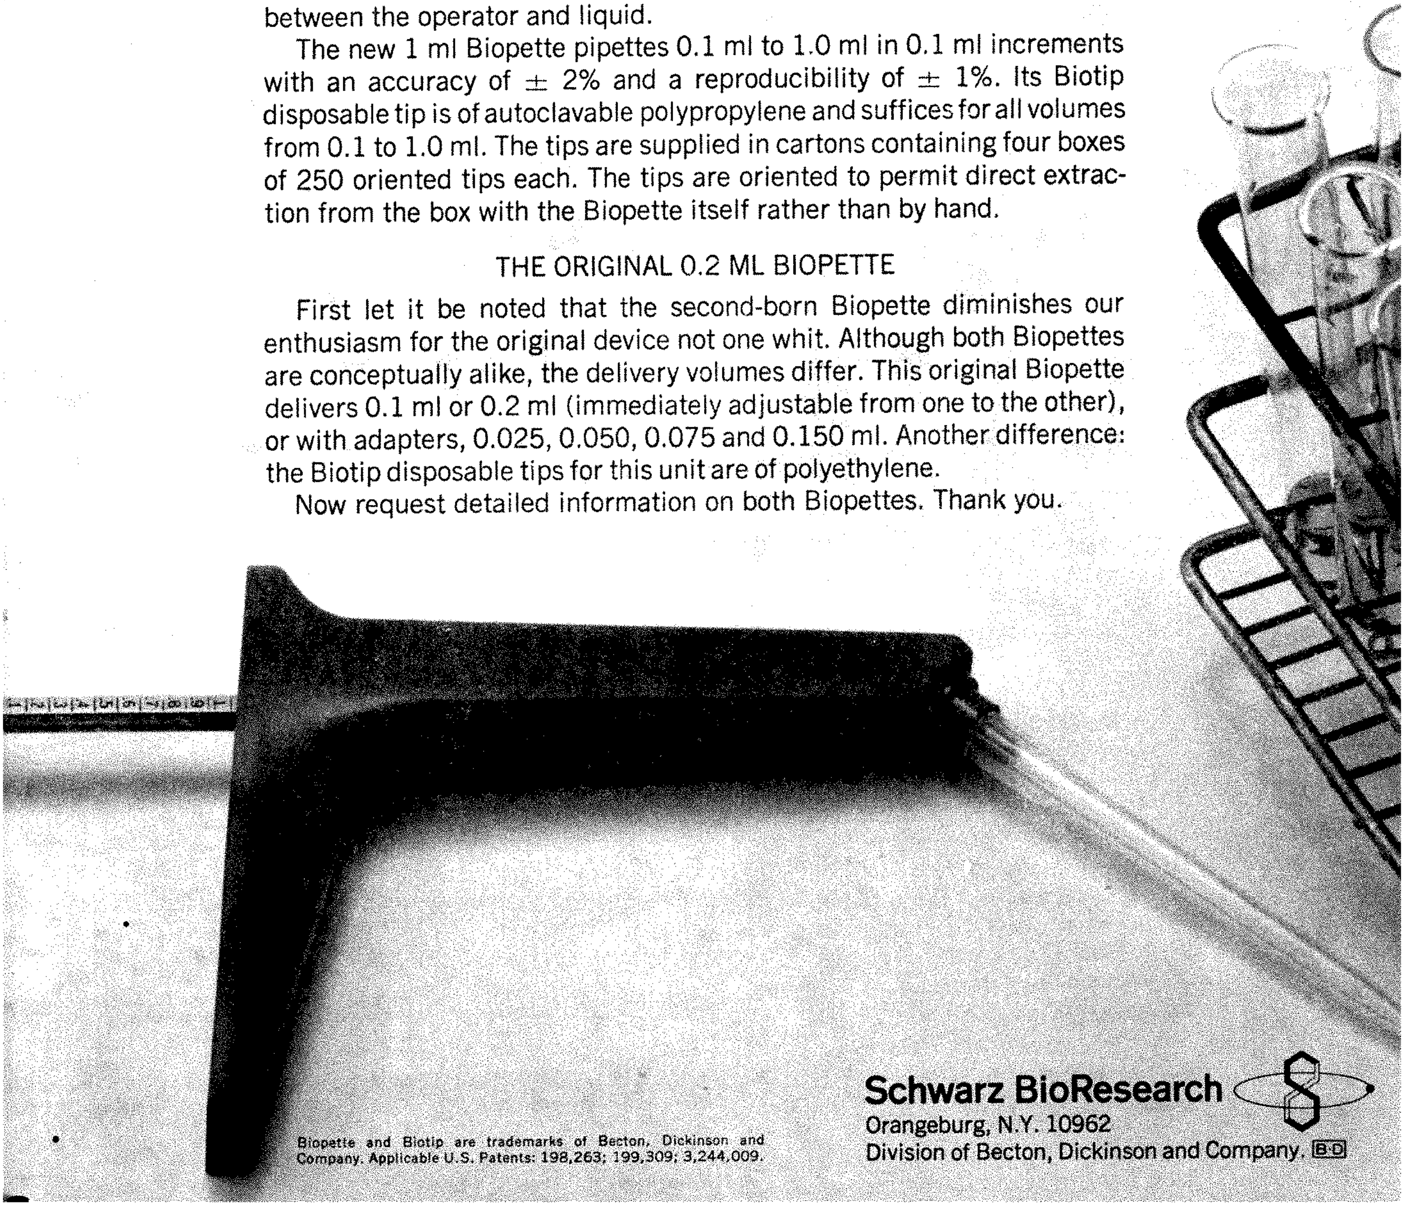
And lest you have forgotten these advantages: Biopettes (both of them) make repetitive pipetting fast, simple, and accurate. Both Biopettes avoid the problems of contamination and washing because the measured aliquot is held in the disposable plastic tip and doesn't enter the unit itself. Both Biopettes permit rapid switching from one liquid to another by simply changing tips. And both Biopettes eliminate contact between the operator and liquid.

The new 1 ml Biopette pipettes 0.1 ml to 1.0 ml in 0.1 ml increments with an accuracy of ± 2% and a reproducibility of ± 1%. Its Biotip disposable tip is of autoclavable polypropylene and suffices for all volumes from 0.1 to 1.0 ml. The tips are supplied in cartons containing four boxes of 250 oriented tips each. The tips are oriented to permit direct extraction from the box with the Biopette itself rather than by hand.

THE ORIGINAL 0.2 ML BIOPETTE

First let it be noted that the second-born Biopette diminishes our enthusiasm for the original device not one whit. Although both Biopettes are conceptually alike, the delivery volumes differ. This original Biopette delivers 0.1 ml or 0.2 ml (immediately adjustable from one to the other), or with adapters, 0.025, 0.050, 0.075 and 0.150 ml. Another difference: the Biotip disposable tips for this unit are of polyethylene.

Now request detailed information on both Biopettes. Thank you.



Biopette and Biotip are trademarks of Becton, Dickinson and Company. Applicable U.S. Patents: 198,263; 199,309; 3,244,009.

Science is Neutral this Time

THE election which the British Prime Minister has arranged for June 18 will differ markedly from that of six years ago, when Mr Harold Wilson was first elected to office. Then the great cry was that what he called the "white-hot technological revolution" would make it possible for Britain to become a much more prosperous place. Since then, everybody—Mr Wilson included—has learned that rapid industrial change is a good deal more difficult than that. For much of the past six years, moreover, the anxiety which he has shared with a good many of those who elected him is whether the British economy would survive at all. The election has come out of the blue because the prospects, for the time being at least, are good. The Conservatives may complain, during the weeks ahead, that the economic indicators will take on a more sombre appearance in the autumn, when wage and salary increases will begin to take their toll and when the troubles of the United States economy may have an influence in Europe, but there is no doubt at all that Mr Wilson's strongest card in the election ahead will be his steadfast reputation for saying that everything would come right in the end. For the time being, at least, there is no sign that bankruptcy is around the corner. It is only natural that Mr Wilson and his colleagues should ask for another spell in office as a reward. This time, in all probability, very little will be heard of the technological revolution.

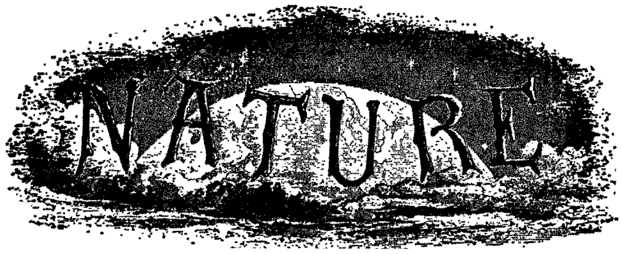
A complete moratorium on technical discussions in the weeks ahead will, however, be a misfortune, for there are several matters which need to be discussed. The Ministry of Technology's green paper on the reorganization of public science is one obvious issue which could usefully be clarified if not resolved during the election campaign. This might also be an occasion on which to press the British Government and its would-be successor for a clearer statement of policy towards the universities. Is it, for example, now commonly agreed that there will be no great expansion of graduate education in the years ahead ? How much weight must be given to the impression that both of the major British political parties find this item in their annual budget something of an embarrassment ? If the white-hot technological revolution has not happened, nobody will dispute that there has been a transformation of the Labour Government's expectations of science and technology.

Fairness therefore requires it to be understood that the government has done a sensible job in the management of basic research in the past six years. The apparatus of the research councils has worked smoothly and well. The Science Research Council in particular has been able to graft onto its traditional functions more adventurous activities. To be sure, among some academics there is now a measure of surprise that the Science Research Council's declared policy of concentrating support for particular fields of research on a few institutions, originally acclaimed, should now have turned out to be painfully effective, but this is only a measure of its success. In the relationship between higher education and research, the retiring government's most serious weakness has been the attempt to build up in parallel with the university system the whole apparatus of the polytechnics—it remains to be seen whether it will be possible for these two systems to coexist without an almost endless waste of resources and of young people's hopes and talents. No harm would come if the government were stimulated by the discomforts of a general election to think again about the wisdom of its arrangements for the development of polytechnics. At the same time, there is every reason why it should be reminded that there is still important work to be done in the further development of the research councils. There would be advantages in concentrating university relations in one of the councils, presumably the Science Research Council, freeing the others for more practical objectives. It would also make sense if some of the money at present provided by the University Grants Committee for university research were directed through the somewhat competitive channels of the research councils—in the long run that could be one of the most powerful incentives to innovation, uncomfortable though it might be for the universities.

Policy on industrial research is much more controversial, and the green paper on the organization of some of the government laboratories, intended as a focus for public discussion, is bound to become a focus for moderate dissension. The proposal is that the research and design establishments of the Atomic Energy Authority, together with some of the public laboratories such as the National Physical Laboratory, should be turned into a single organization living in part off public funds and in part off what they can raise by jobbing out their services either to government departments or to industry. The most obvious defect of the scheme is that the laboratories do not include those working on defence research, essential if the new British Research and Development Corporation is to function well in the fields in which there is most useful work to do—telecommunications, for example. By itself, this should be enough to make the project founder. But there are also problems about the extent to which the new corporation will actually be able to sell its services. The way in which it is likely to be composed, it is bound to seem to many people a pale shadow of the Atomic Energy Authority, itself in recent years a pale shadow of its former self.

In these circumstances, nobody should be surprised that the Conservative Party would take a more drastic line with those research establishments which have outlived their original functions, promising the men and women concerned monetary incentives to retire early, and would at the same time sublet much more of government research to industrial companies. There is a great deal in the arguments which have led to the formulation of this policy. The weakest part of the government's case is that nobody knows at present just what kind of work the British Research and Development Corporation would carry out. It is still too much a piece of imagery, and it would be a public service, since there has to be an election after all, if the occasion could be used to force the government to provide a more detailed prospectus of its intentions.

100 Years Ago



AN article of food has lately been introduced which has found its way into every grocer's and chemist's shop in the country, and for which there is in all parts of the world a vast demand. This substance is variously called the Extract of Meat, the Juice of Flesh, Liebig's Extract, and in Latin, *Extractum Carnis Liebigii.* The name of Baron Liebig, the great chemist, is more especially connected with this compound, as he has undoubtedly the merit of having first called attention to it as a valuable article of diet. In his "Familiar Letters on Chemistry," he devotes a letter to vegetable and animal food, and gives an account of their various chemical components. He shows with regard to all animal flesh, that besides fibrine, albumen, gelatine, and fat, it contains certain other constituents which may be separated from these by a simple process of infusion, straining, and evaporation. The substance thus obtained is the extract of flesh.

From Nature, **2**, 62, May 26, 1870.

OLD WORLD

FISHERIES

Compromise over Salmon

MOVES by Britain and other salmon breeding countries to ban the fishing of salmon in the North Atlantic have for the moment been defeated. At a meeting of the North-East Atlantic Fisheries Commission (NEAFCO) in London from May 6–11, the delegates decided instead to limit fishing in general to the period between May 5 and July 1 each year, and to ban it altogether only in two small areas to the north of Norway. The agreement does not cover the most important high seas salmon fishing grounds, which are off the coast of Greenland; next month, however, the meeting of the International Commission for North-West Atlantic Fisheries (ICNAF) is expected to reach substantially similar conclusions for the Greenland area, because the member countries of NEAFCO and ICNAF are largely the same.

Denmark has been the most vociferous opponent of a complete ban, urged chiefly by Britain and Canada because their freshwater and inshore salmon catches are, they claim, being threatened by Scandinavian drifters which pirate the salmon on the high seas. At the NEAFCO meeting last year, a proposal to stop high seas fishing of salmon for ten years failed to gain a big enough majority for acceptance. The opponents —Denmark, Sweden and West Germany—came out this year in favour of restrictions which, as well as imposing a forty-five week close season, prohibit the catching of fish smaller than 60 cm and limit the kinds of net that can be used. Britain and Iceland voted against the restrictions, but the general feeling at the meeting was that it was better to take advantage of the partial concessions by Denmark, Sweden and West Germany than to continue in support of radical measures whose adoption would again be made impossible by these three countries.

Unless any country objects within ninety days, the agreement becomes binding from the beginning of 1971, and will be reviewed after two years. As they stand, the restrictions are not as severe as they may seem. For one thing, there is already a natural close season for salmon in their high seas feeding grounds because they spend much of the year returning to their home rivers to breed. More important, there is no limitation on the number of boats that can exploit the salmon, so that catches could be kept up by involving more fishermen. This settlement, however, is probably all that can be achieved for the moment without damaging international relationships—between Britain and Denmark in particular—and does at least acknowledge the lack of direct evidence for a fall in coastal and freshwater catches. Should stronger evidence of diminishing stocks emerge, one course of action that has been suggested in several quarters is a boycott of Danish exports.

Unlike the Atlantic salmon, the North Sea herring has been quite clearly overfished in the last few years, and in several areas there are simply no herring left to be caught. The dangers inherent in the more capacious nets that have been used since 1965 were recognized by the NEAFCO meeting, which decided that herring should not be fished in the North Sea during May and from August 20 to September 30.

This is the first time that catches of herring have been limited internationally; the measures are provisional pending the negotiation of a quota system to halve the annual harvest. Herring are far more important economically than salmon, but the salmon problem has been causing most of the controversy because of the money that goes into breeding and conservation and the value of the fishing rights in salmon rivers. No single country can be blamed in isolation for the overfishing of herring, although the Scandinavian countries have large herring industries, and Russian and Polish ships have of late captured a growing proportion of the fish.

GOVERNMENT RESEARCH

What to Do about Harwell?

THE Confederation of British Industry has now come up with its comments on the plan by the Ministry of Technology for the reorganization of government research laboratories. Widely seen as an attempt to solve the problem of what to do with the laboratories of the Atomic Energy Authority now that the initiative is being shifted to the nuclear power companies, the government plan involves the setting up of what is being called the British Research and Development Corporation. This would be made up of the Harwell and Culham establishments of the AEA, the reactor group, five of the research laboratories of the Ministry of Technology occupied with civil research, and the National Research Development Corporation.

What the CBI dislikes about the plan is that it will not encourage the right kind of links between the laboratories and the industries which the ministry would like to see the laboratories provide. Obviously, the CBI believes that the closer research and development work is done to the point of application the better, with industrial laboratories as the ideal place. But, unlike other organizations which have been criticizing the plan since its publication as a green paper in January, the CBI has some alternative suggestions.

It identifies as the most urgent problem the need to deal humanely with the excess staff in the Atomic Energy Authority, left over from the time of intensive research into atomic energy. The CBI recommends several steps which might be taken, including the establishment of a working group to help with redeployment, which would take into account the future requirements of the Atomic Energy Authority as defined by the Atomic Energy Board which Mintech proposes. Government laboratories, research associations and educational establishments are seen as the likeliest places where the excess staff might find work, but the CBI stresses that the government has important financial responsibilities to those who go outside government service.

The CBI would like to see what is left of the research and development resources of the authority become a research association serving the nuclear power industry. The non-nuclear activities which the government has been encouraging in the authority would then have to be run separately by the Ministry of Technology.

Leaving aside the Atomic Energy Authority, the CBI has considered whether the five research establishments of the Ministry of Technology included in the green paper ought to be placed in a smaller version of the BRDC. But the conclusion is that the disadvantages of having in the same corporation five laboratories working in different fields outweigh the advantages, and the CBI prefers a modest reshuffling of the laboratories among government departments. The Ministry of Technology should retain responsibility for the National Engineering Laboratory, the National Physical Laboratory, the Warren Spring Laboratory (although here there is a need for links with the Ministry of Housing and Local Government), and the Forest Products Research Laboratory (but in this case the CBI admits there is a case for transfer to the Ministry of Public Building and Works). But the CBI joins with the Institution of Civil Engineers in recommending that the Hydraulics Research Laboratory become the responsibility of the Natural Environment Research Council, on account of the work on conservation undertaken by the laboratory.

The final component of BRDC, the National Research Development Corporation, whose job is to encourage the application of government and private research, ought to be seen to be independent of any large organization such as BRDC, and the CBI paper says there seems to be no reason why NRDC cannot continue as it is.

But running through all the discussions of the government's plan, including the latest important contribution from the CBI, is the fear that BRDC will be a cover-up for the running down of laboratories which do not pay their way. This is because the Ministry of Technology has set the target of BRDC being self-supporting by 1975, by earning what most critics believe is a hopelessly ambitious proportion of its annual cost of £70 million from private industry. The CBI's comment is that it would be wrong for the new corporation to be faced with a major redundancy in its staff as one of its first problems.

UNIVERSITY GRANTS COMMITTEE

Pays Piper but Calls No Tune

BRITISH universities have more academic freedom than their counterparts in any other country, and they are better off economically under the present system of allocating grants than they would be under any other system. The University Grants Committee can, of course, take most of the credit for this situation, because it places itself between the universities and their chief source of finance, allowing them to tread their own academic paths without having constantly to bow down to some outside authority.

This tribute which, when set against most utterances about academic freedom, seems notably uncontroversial, was made last week by Sir John Wolfenden, himself a past chairman of the UGC, in a lecture given to the Royal Society of Medicine. The conclusion seems a long way removed from the hysteria which has been stirred up by the recent allegations of industrial control at the University of Warwick.

Compared with universities in the United States, British universities can count themselves lucky. Sir John painted a vivid picture of presidents of private universities in the US travelling the country to drum up funds from business corporations and foundations, so that their research can be conducted free from any federal strings. But, said Sir John, "it is idle to pretend that funds which come from these sources are without strings", and he went on to give the advice to those attempting to establish an independent university that "it is an illusion to suppose that a private university is, by being private, academically independent. And those who contemplate establishing one in Britain should take to heart the experience and advice of their American colleagues before they embark on a will-o'-the-wisp enterprise here".

At the other extreme, American state universities are, according to Sir John, firmly in the pocket of the state government. The university president has to spend his time lobbying the state legislators to try to persuade them to do what he would wish to see done or, more often, to try to dissuade them from taking decisions which would undermine the academic freedom of his institution even further.

It is only the existence of the University Grants Committee that has prevented a similar situation occurring in Britain. The UGC acts as a buffer between the universities and the government so that, although the government subsidizes the universities to the tune of about £250 million a year, it keeps its fingers out of the internal affairs of each institution. "The government as such and the universities as a body never meet to argue about money, still less about the universities' internal affairs; between the two stands the UGC, ready to have its bottom kicked by both." But the situation is changing. The UGC can no longer be merely a go-between but must take an overall view of the situation, and plan its strategies accordingly. Centres of excellence should be built up in a few places, and duplication of effort avoided wherever possible. And there is nothing wrong with the UGC or the comptroller and auditor general encouraging the universities to be more economical.

What of the future? Sir John was remarkably reticent when it came to making predictions, but he did finish up on a cautionary note. "There is a danger," he said, "that a government might wish to take over the universities and make them the instrument of some policy or other which might be totally antagonistic to the academic freedom in which we all believe. That has happened elsewhere, and it would be naive to suppose that it could never happen here. More insidiously, because less obviously, Parliament, acting through a select committee, believing itself to be responding to public opinion, might exert pressure on a government to ensure that the universities did what they were told." But such a development, he promised, would only take place over the dead body of the UGC.

FOOD

Making Mincemeat of Starch

A CHEAP way of making protein from carbohydrates, under development by Ranks Hovis McDougall Ltd (RHM), has proved promising enough to attract backing worth £500,000 from the National Research Development Corporation. The key to the process is a fungus that can grow on carbohydrate residues, and the product, known as A3/5, is claimed to have the nutritive value of milk protein. A team at the RHM Lord Rank Research Centre in High Wycombe has already used A3/5 as the basis of a simulated meat, which is not yet entirely palatable but does at least lack the unpleasant aftertaste of many other protein concentrates, particularly those from soya.

The fungus is a strain of *Penicillium notatum*, but RHM will not reveal what the strain is until the process has been patented. According to Professor Arnold Spicer, director of research, RHM has a three-year lead over its nearest rival (a Japanese company) and the chief competitive advantage of A3/5 over proteins from other sources is that it will eventually sell at something like half the price. The National Research Development Corporation is equally enthusiastic and, although it has gone to some lengths in looking at other attempts to produce edible proteins, it is not planning to finance any more projects in the near future.

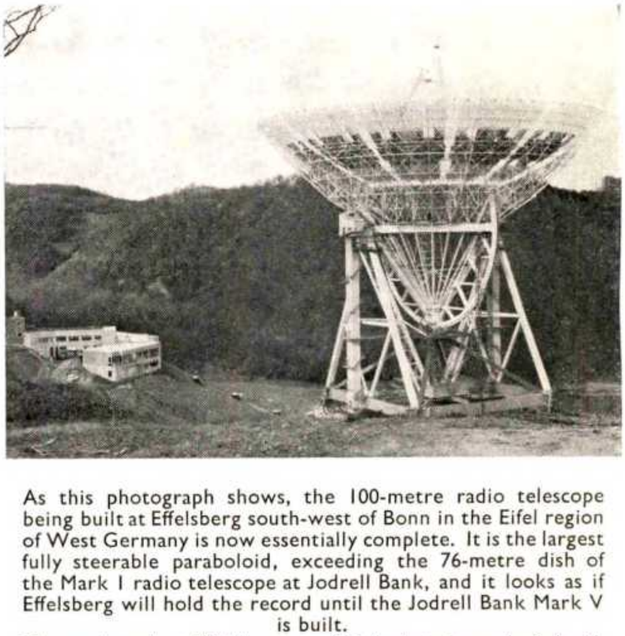
Almost any carbohydrate source can be used to make A3/5. One incentive for developing the process was that RHM wanted to find a use for its waste starch, although full-scale factories would presumably exploit local crops such as potatoes or cassava. A small plant which RHM is to open at High Wycombe next year will be starting from milk whey and molasses, together with nitrogen in the form of ammonia, and is intended to convert six tons a week of carbohydrate into three tons of A3/5. The output will be used for large-scale trials on farm animals; evaluation on humans is not planned until 1973.

The making of the protein is one thing; the marketing is another. Not much attention has been given to the form in which A3/5 might be presented, but its most

---

RADIO ASTRONOMY

Germany's National Dish



As this photograph shows, the 100-metre radio telescope being built at Effelsberg south-west of Bonn in the Eifel region of West Germany is now essentially complete. It is the largest fully steerable paraboloid, exceeding the 76-metre dish of the Mark I radio telescope at Jodrell Bank, and it looks as if Effelsberg will hold the record until the Jodrell Bank Mark V is built.

The steelwork at Effelsberg was finished at the end of April, and the next three months should see the final adjustment of the surface panels, the connexion of the computers and the telescope drive, and the installation of electronic equipment. The whole collecting area is designed for observations down to 5 cm and the central portion, 60 metres across, is accurate enough for work at 3 cm. Dr R. Wielebinski, director of the Max Planck Institute for Radio Astronomy at Bonn, expects preliminary observations to begin with the new telescope later this year.

likely use would be as a supplement to protein-deficient food, mixed into cereals or biscuits for people who cannot afford a balanced diet but are nevertheless suspicious of foods that are said to be good for them. Certainly, not all attempts to sell protein extracts made from soya in under-developed countries have been wholly successful.

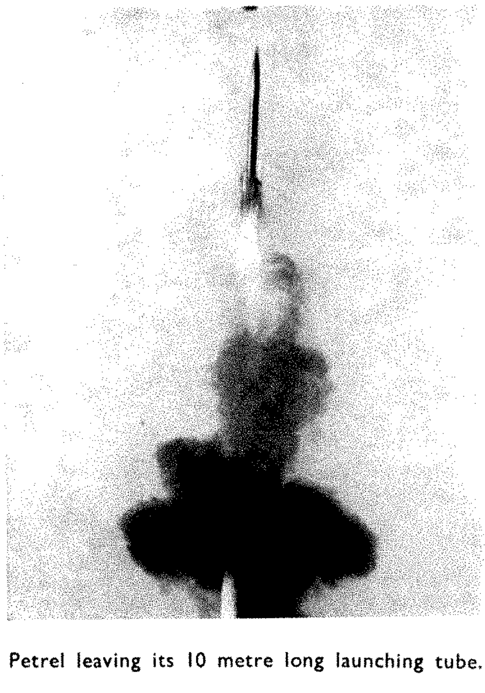
Professor Spicer, at least, is confident that A3/5 will fare better than the proteins obtained by growing yeast on petroleum hydrocarbons because A3/5 contains a better proportion of the nutritionally essential sulphur amino-acids. But the oil companies will be the first to the market: British Petroleum will be turning out yeast from its factory at Grangemouth in Scotland by the middle of the year and its French subsidiary is opening a protein plant next year. BP, however, has decided to use its product as an animal feed and the market still seems to be open for anyone who can produce proteins that humans would stomach.

ROCKETRY

Boost for Atmosphere Research

It seems almost certain that an improved version of the highly successful Petrel rocket will be developed by Bristol Aerojet Limited, with the backing of the Science Research Council. More than forty Petrel rockets have been fired since their introduction in February 1968 into the British programme of rocket investigations of the upper atmosphere. Designed as a cheap means of providing a sounding rocket chiefly for university experiments, Petrel can carry a payload of 13 kilograms to an altitude of 140 km. By adding about 15 centimetres to the 3·3 metre length of the standard version, altitudes at least 40 km higher ought to be within reach with the same 13 kilogram payload.

Although Petrel is only 19 centimetres in diameter, it seems to be big enough to carry the sort of payloads required for upper atmosphere research. In some cases the payload capability of 13 kg has been sufficiently in excess of the actual weight of the instrumentation that ballast has been carried to preserve the balance of the rocket. Thus the extra performance of the stretched Petrel is unlikely to be used to carry heavier payloads at the expense of altitude—Bristol Aerojet estimates that it could carry an extra 2 kg or so by limiting the altitude to 140 km.



Petrel leaving its 10 metre long launching tube.

Two further improved versions of Petrel are on the drawing boards at Bristol Aerojet waiting for backers. There is a Petrel 200 designed to carry a payload of 18 kg to altitudes of 220 km using three boost motors, and the Petrel Thrush to reach 350 km with a 5 kg payload. This uses the same small booster that helps to launch the standard Petrel rockets, coupled to a two stage rocket based on the Petrel as first stage.

But the order for Petrel rockets from the European Space Research Organization which Bristol Aerojet has been hoping for has not been forthcoming. Expectations were raised a year ago after the Science Research Council used the ESRO range at Kiruna, Sweden, for a series of eight Petrel launches in an investigation of the polar ionosphere. The performance of rockets in the polar atmosphere is notoriously unpredictable, and this seems to have been the first occasion when all the rockets in a Kiruna campaign have landed within the confines of the range. By all accounts the ESRO officials at Kiruna were impressed, but uncertainty about the shape of the ESRO sounding rocket programme in the future is thought to be the reason why Petrel is still used only by Britain.

EUROPEAN SPACE

ELDO's Goodbye to Woomera

The final attempt to launch a satellite from the Woomera range in the development programme of the Europa 1 rocket of the European Space Vehicle Launcher Development Organization (ELDO) will now take place on June 8. Postponed several times from the original launch date in November last year, the firing is intended to place a small Italian test satellite into an elliptical orbit of 400 km by 2,000 km. Thereafter the remaining firings in the ELDO programme will be from the French base at Kourou in French Guiana.

This will be the third orbital attempt by ELDO. Previous tries in November 1968 and July 1969 both ended in failure when the German third stage cut out prematurely. Coming directly after two test flights with dummy third stages in 1967, which were both unsuccessful because the French second stage failed to ignite, this record makes the ELDO programme the most disappointing aspect of the European space effort. Another failure shortly before the European Space Conference which is expected to meet in June to discuss European space policy would obviously be the worst impression that ELDO could make.

If the June firing is as successful as everyone hopes, a 214 kg test satellite will be launched in a direction 4·5 degrees east of north from Woomera. The prime aim of the satellite is to monitor the launch and the injection into orbit, and to make sure that the correct orbit is achieved. It will also contain an experimental package built by five members of the European Conference on Satellite Telecommunications—Belgium, Denmark, Italy, Norway and Sweden—to carry out communications tests.

The next step in the ELDO programme is the testing at Kourou of the Europa 2 launcher, which is Europa 1 fitted with a perigee stage so that a geostationary orbit can be achieved. Two firings are planned for 1971. Then everyone hopes that ELDO will be ready to carry out its first launchings for customers.

MAGAZINES

Birth of *Recherche*

A NEW French magazine has risen to join the distinguished band of scientific monthlies such as *Scientific American* and *Science Journal* which cater on a popular level for scientists as well as non-scientists. *La Recherche*, whose first issue has just appeared, is the successor to *Atomes* but aims to be more readable as well as more open to the applied and development aspects of research. The editor, M. Michel Chodkiewicz, who was also the editor of *Atomes*, describes *La Recherche* as being for "all those whose interest in scientific and technological advances is not confined to their own specialism".

With an admirably European opening, the first issue contains interviews with Professor Hans Leussink, the West German Minister of Education and Science, and Mr Anthony Wedgwood Benn, the Minister of Technology. Then follow four excellent feature articles, including a discussion of ceramic materials by R. W. Davidge of Harwell and a well illustrated essay on viruses and cancer by Luc Montagnier of the French National Scientific Research Centre.

In the last section of the magazine are brief items on French and international scientific news and longer articles on science policy and particular research topics.

Although at 7.50 francs a copy the magazine is not cheap, the indications from the first issue are that it will be good value for money. Copies may be obtained from 4 Place de l'Odeon, Paris 6^e, the subscriptions being 75 francs for France and 90 francs from abroad.

WATER RESOURCES

Filling Up the Thames

WITHIN the next ten years, underground aquifers could supply at least another 100 million gallons of water a day to the River Thames when its flow is reduced in hot, dry summers. Boreholes sunk by the Thames Conservancy in the Lambourn Valley in Berkshire have shown that it would be feasible to pump up water occasionally from the chalk and limestone formations in the Thames catchment area to supplement the flow of water into streams, such as the River Lambourn and the Winterbourne Stream, and ultimately into the River Thames. When the extra water is no longer needed, the pumps could be turned off, and the underground reservoirs would gradually fill up again during wet periods.

Two thirds of London's water and that for twenty-four other water undertakings is drawn from the River Thames. Demand is rising every year and the river's resources are already insufficient to meet the demand in dry spells without reducing the flow of water over Teddington Weir to below its statutory minimum level. There is therefore some urgency about the need for new large supplies of water for London, and the conservancy believes that it has found a solution with its pumping scheme which could be implemented at about one third to one quarter of the cost of conventional surface reservoirs and which would have very little effect on agricultural land. Analyses of the water pumped up from the chalk formations in the test area have shown it to be of the same chemical quality as the water naturally discharged to the rivers, and sampling of the fish and invertebrate fauna in the River Lambourn and Winterbourne Stream has so far shown that experimental pumping causes no adverse ecological effects. With the experience gained from its pilot scheme in Berkshire, the conservancy plans to extend the pumping scheme to other areas in the Thames catchment.

Farther downstream, there is news that the defence structure across the Thames which will protect London and Lower Thames-side from a tidal flood is to be a drop-gate barrier between Woolwich and Blackwall reaches. In a recent parliamentary reply, Mr Greenwood, Minister of Housing and Local Government, announced that the government has asked the Greater London Council to recommend a site for a barrier in that area so that work on a design can be started. The GLC has also been asked to investigate, with the London Transport Board, the need for temporary flood defences while the barrier is being built. Lord Kennet will continue to chair the policy committee which has been supervising since 1968 the studies of the GLC and other authorities into various defence schemes.

The Minister's decision gives support to the recommendations of a GLC research team which reported last January (see *Nature*, **225**, 403; 1970) that, of all the various types and location of a fixed barrage or a movable barrier across the Thames that it had investigated, it favoured a barrier in the Woolwich area, or failing that, one at Crayfordness farther downstream. A barrier of the drop-gate type at one of those two sites could operate, it was suggested, by closing at times of great risk at a point during the ebb tide, reopening on the following incoming tide unless there was a warning of a surge when it would remain shut. It was estimated that a barrier at Woolwich would take about seven years to build at a cost of about £50 million. After Mr Greenwood's announcement GLC officials said that it might be possible to combine the Woolwich barrier with another road bridge across the Thames.

RESEARCH ASSOCIATIONS

A Non-Ferrous Jubilee

THE uncertainty between now and the British election on June 18 will place a moratorium on the debate about the present government's plans for the reorganization of the research laboratories of the Ministry of Technology (see p. 679). But if the proposed British Research and Development Corporation is eventually established, then it will be in direct competition with the research associations for scarce contract work from industry. One research association which believes it is in good shape for the battle is the British Non-Ferrous Metals Research Association, which this week is celebrating its first fifty years.

Set up in Birmingham by the Department of Scientific and Industrial Research, the research association is now fast outgrowing its present site near Euston Station, London. Last year's income was £700,000, almost double what it was five years previously in 1965, and it supports a staff of 195. Most of the increase has come from contracts and for projects supported by small groups of members, such as work which the association is doing on continuous casting and on hydrostatic extrusion. By contrast the income from membership subscriptions has risen less than dramatically, last year being still slightly less than twice what it was in 1961.

This seems to be because the British Non-Ferrous Metals Research Association has by now collected all the members it can in Britain. Turning from this saturated market, the research association has recently been looking abroad for members and at present about a quarter of the income is attributable to overseas contributions. This is an area of support which the director of the association, Dr A. J. Kennedy, clearly intends to foster.

Dr Kennedy sees the future of the association as lying more in large scale projects, each financed by only a few of the members. In particular, the interests of the research association have tended to move toward the engineering aspects of metallurgical plants. But the intention is to stay at the Euston site while looking for a place to carry on the large-scale work. The continuous casting experiments are located at Widnes and the hydrostatic extrusion at Enfield, for example.

CONSERVATION

Rape of Armenia

by our Soviet Correspondent

THE importance of conservation and particularly of land conservation was grasped relatively late by the Soviet Union, largely because of its vast expanses and great natural resources. Consequently, from time to time, conditions in individual republics and regions can reach and pass the danger level without, apparently, attracting the immediate attention they merit.

A case in point is a recent disturbing report from Armenia (*Pravda*, May 14, 1970). Here, it would seem, the widespread programme of irrigation and soil improvement has lost much of its impact because of erosion, particularly in the mountain regions. The figures for these regions are disturbing; the estimated annual loss to collective and state farms is 40–80 per cent of the harvest as well as 12 million tonnes of productive soil. More than 90,000 hectares of virgin forest have been felled (presumably during the whole period of Soviet rule), and recent reafforestation schemes have so far replaced only 3,000 hectares. Anti-erosion measures are far behind schedule; over the last two years, only a third of the new anti-erosion irrigation schemes have been completed and less than half of the planned terracing of steep slopes. Likewise, schemes to turn over non-arable land to stock-rearing and to bring waste land under hay crops have fallen far short of target. Although long-term grass cultivation has been recommended as a highly effective anti-erosion measure, the area of land under grass still continues to fall rapidly. More and more irrigation schemes are being introduced (the best means of soil conservation—particularly in the geological conditions of Armenia), but are not being used to their full capacity—the case is cited of one particular installation, designed to serve 12,000 hectares which, in fact, is irrigating only some 7,000 hectares. Finally, since some of the best agricultural land in the republic, including market gardens, vineyards and well-irrigated arable land, lies close to urban centres of population, the expansion of these centres outwards is causing another type of "erosion". The new developments at Erevan are particularly cited in this respect.

Some two years ago the Presidium of the Supreme Soviet of Armenia passed a special resolution by which all land suitable for agricultural purposes and at present used otherwise or not in use should be restored to agriculture. This, the latest report notes, has only "slightly" been implemented, and recultivation has been carried out only in "insignificant areas".

The closing paragraphs of the report are illuminating. No one, it stresses, can legally be called to account for soil erosion and land loss despite the effect on the material wealth of the republic. The concept of responsibility is fundamental to the thought of the Soviet planners; should plans fail to be carried out in their entirety, somebody is found, at some level of administration, to have been responsible, whether culpably or through negligence. The disclaiming of responsibility implied in the report is evidence both of the late entry of the concept of conservation into Soviet planning and also of the even later impact of the idea into the consciousness of the average citizen, whom for fifty years the publicists have exhorted to further and further efforts of construction. Now that the emphasis is shifting, a whole new method of approach seems necessary.

POWER SUPPLY

Cool Cables Getting Hotter

A NATIONAL grid based on superconducting cables carrying direct current may sound like a pipe dream today, but the Central Electricity Research Laboratory is confidently predicting that, given ten—perhaps fifteen—years, the expected rise in power demand will strengthen the economic argument for such cables. The attention being lavished on the technical problems of superconducting cabling was evident at the CERL's open days which were held last week at Leatherhead in Surrey.

Research on superconducting transmission systems may seem foolish in view of what happened to the magnetohydrodynamic research project a few years ago. But there are some important differences. Superconductivity is, after all, a rapidly developing technology. Demand for power is continuing to double every ten years, and the case for superconducting cables grows with each additional megawatt that has to be channelled down a transmission line. At the present rate of expansion a simple extrapolation suggests that cables carrying up to 10,000 MW will be needed by the end of the decade, and superconducting cables start to become economically viable at this sort of load.

The choice between a.c. and d.c. superconducting cable links is a fine one and CERL is not yet committed to either form. The lack of inductance in a d.c. cable and the attendant lack of restriction in the shape of the cable has to be weighed against the need for a.c. to d.c. converters at the terminals. The development of solid state converters, however, has done much to simplify this problem. Cables to carry a.c., on the other hand, have to be built in annular sections, consisting of an outer surface superconductor (niobium at CERL), a region of bulk superconductor (niobium-titanium alloy) and a layer of normal metal to short the cable should any section of superconductor heat up and become resistive. The metallurgy of forming this sort of cable is still a major preoccupation at CERL, and there is no doubt that engineers are leaning steadily towards the d.c. system should the enormous cost of cooling to 4 K turn out to be justified by events.

But CERL is not gambling exclusively on sending high loads under the ground. Ultrahigh voltage overhead cables operating at around a million volts are being studied at CERL in conjunction with sister laboratories in France and Italy. CERL is concentrating on the problems of insulation, where its expertise is greatest, and has recently spent a quarter of a million pounds on an extension to its high voltage line near Brighton. Two hazards being studied are sudden surges of power and leakage due to moist conditions. The French and Italian laboratories are looking into questions of power and conductor design.

CERL is also investigating the possibility of taking voltages significantly above the present 400 kV under the ground in normal cables insulated with sulphur hexafluoride gas. The Japanese power authorities have recently completed work on an alternative underground cable using plastic insulation, which will be used to feed power into Tokyo.

SOUND

Physics ma non Troppo

A GRANT of £15,000 has been awarded by the Leverhulme Trust fund for an interdisciplinary project in physics and music at University College, Cardiff. The chief beneficiary is Mr K. Winters, who has the rare qualification of first class honours degrees in both physics and music. He will participate in a teaching programme to include courses in electronic and computer music at both undergraduate and postgraduate level and will carry out research into the capacity of computers to generate and manipulate sounds for musical purposes and for testing the mechanism of hearing itself.

Although musicians must assimilate some knowledge of the physics of sound during their training, physicists are rarely graced with a reciprocal obligation. It is pointed out at Cardiff, however, that the interface between physics and music is of direct relevance to many practical problems, including the psychological effects of hearing, the production of computer generated sounds and the analysis of other existing sound patterns. Apart from work at Cardiff, in which five research workers are involved, there are also teams working on similar problems at Princeton University and Bell Telephone Laboratories in the United States.

Parliament in Britain

Nuclear Powered Merchant Ships

THE Ministry of Technology has decided not to go ahead with the development of a nuclear powered merchant ship. Mr Harold Lever, the Paymaster General, said in reply to a question from Mr Edwin Brooks that a study group has examined the economics of nuclear powered vessels, both on a single ship and on a fleet basis, and has concluded in a report to the Minister of Technology that these ships will not be competitive with conventional vessels, at least in the foreseeable future. The report also suggests that the development of nuclear powered vessels would not help short-term employment prospects in the shipbuilding industry. (Written answers, May 15.)

Marine Pollution

THE government intends to ratify the International Convention on Oil Pollution Damage which was signed in Brussels in November last year. Announcing this intention, Mr Goronwy Roberts, Minister of State, Board of Trade, said that the convention will considerably improve the position of the claimant in the event of marine pollution damage, and he hopes that other countries will follow Britain's lead. The necessary legislation, he said, will be prepared as soon as possible.

In reply to an earlier question, Mr James Hoy, Joint Parliamentary Secretary to the Ministry of Agriculture, said that the government has allowed some industrial firms to dump polychlorinated hydrocarbon residues in sealed containers in very deep waters. All applications, he said, are very carefully examined to ensure that the disposal arrangements will not cause human or other biological hazards. Mr Tam Dalyell had asked what was the policy of the Ministry of Agriculture, in view of the established effect of chlorinated hydrocarbon residues on marine life. (Written answers, May 13.)

Adult Education

MR WILLIAM ROSS, Secretary of State for Scotland, announced that he has set up a committee under the chairmanship of Professor K. J. W. Alexander of the University of Strathclyde, to look into the provision of adult education in Scotland. The terms of reference of the committee are to consider the aims of adult courses which are educational but not strictly vocational, and, bearing in mind the need to use resources more efficiently, to make appropriate recommendations. (Written answers, May 15.)

Polytechnics

THE desirability of siting polytechnics close to other institutions of higher education is not one of the factors taken into account in choosing the centres to be developed as polytechnics. The initial location of the polytechnics is governed by the location of their constituent colleges, said Mr Gerald Fowler, Minister of State, Department of Education and Science, and although it is best to develop them on a single site, all the local circumstances, particularly the need to make proper use of existing plant, must be taken into account. It is government policy, however, that strong links should be established between polytechnics and the universities, Mr Fowler pointed out, and many polytechnics are being established in towns where universities already exist. (Written answers, May 11.)

NEWS AND VIEWS

Doing without DNA Polymerase

THE quest for a system in which to study the synthesis of DNA *in vitro* seems to have been fulfilled at last. Such synthesis has hitherto been achieved only by the much maligned enzyme DNA polymerase, but in this issue of *Nature* are the first reports of cell-free extracts which seem to lack this enzyme but can nevertheless synthesize DNA. Although there have been doubts for some time as to whether DNA polymerase is responsible for replication *in vivo*, the readiness with which it sets about polymerizing the precursors of DNA, once provided with a DNA template, has hindered attempts to characterize other enzyme systems which may synthesize DNA.

The notion that DNA polymerase does not replicate DNA *in vivo* is supported by the behaviour of a mutant of *E. coli* which lacks DNA polymerase activity when assayed *in vitro*. In spite of its defect, this strain grows well and replicates its DNA in the usual manner. On page 713 Knippers and Strätling describe how they have taken advantage of this mutant to assay cell-free extracts for other replicating enzyme activities. Another way to eliminate the unwanted activity of DNA polymerase is provided by Smith, Schaller and Bonhoeffer on page 711, who report the development of an *in vitro* assay system from which this enzyme can be washed out.

Smith *et al.* embed *E. coli* cells in a matrix of agar, fragment the agar, transform the cells into a fragile form (spheroplasts) within the agar fragments, and lyse these by osmotic shock. DNA polymerase and other soluble components can be washed out of the system to leave just fragments of membrane with DNA attached to them. When incubated with deoxynucleoside triphosphates, DNA is synthesized in a semi-conservative manner at a rate of some $1{\cdot}3\times10^3$ nucleotides per second. This synthesis, however, continues for only one to two minutes before ceasing abruptly.

Knippers and Stratling use sucrose gradients to isolate a membrane-DNA fraction from *E. coli* cells infected with phage ϕX174. When supplied with the appropriate substrates, the phage DNA in this fraction replicated semi-conservatively, again at a fast rate, and again ceasing after only a short period (five to ten minutes in this system). By using the *E. coli* mutant which lacks DNA polymerase activity, they are able to suggest that their membrane fraction may contain another enzyme apparatus which can replicate DNA.

These systems mark the nearest approach so far *in vitro* to the form of replication which prevails *in vivo*. The attempts of DNA polymerase to reproduce double stranded DNA *in vitro* proceed at a rate some two orders of magnitude below the *in vivo* rate and produce an abnormal product with strange contortions of the DNA duplex. The membrane replication systems, by contrast, demonstrate semi-conservative replication at a rate comparable with that *in vivo*. And that replication can be achieved by a DNA-membrane fraction is in line with recent theories that there is a link between the membrane and the DNA replicating apparatus of the cell.

A flaw of each system is that replication proceeds for so short a time that it cannot be complete. There is no obvious reason for this—possibilities such as precursor exhaustion have been excluded—but it will be necessary to demonstrate that the whole chromosome can be replicated if sceptics are to be convinced that this system really is that which works *in vivo*.

There remains, of course, the possibility that it is, after all, DNA polymerase which catalyses the synthesis of DNA observed in the membrane systems. It may be that this enzyme is properly active only when associated in some way with the cell membrane, so that its behaviour in other extracts is uncharacteristic. The DNA polymerase mutant may have an enzyme which is altered so that it cannot be assayed alone *in vitro*, but which is active in association with the membrane. These doubts can only be resolved by purification of the membrane systems. This may prove difficult, however, if it turns out that they function only as a complete replicating complex and cannot be broken down into individual enzyme activities.

The physico-chemical demands of the membrane-replication systems are rather different from those of DNA polymerase, and this suggests that it is more likely that they contain some other enzyme. If this is so, what part does DNA polymerase play in DNA metabolism ? This enzyme has a wide range of synthetic and degradative catalytic activities which enable it to undertake almost any action except, unfortunately, the proper replication of DNA. This versatility left it much as an enzyme in search of a function (*in vivo*, that is) until the recent demonstration that *in vitro* it can excise pyrimidine dimers from DNA. These dimers are produced in DNA by ultraviolet irradiation and distort the structure of the DNA double helix. Its ability to excise them suggests that DNA polymerase may be a repair enzyme, that is, it may maintain the correct structure of the DNA duplex by removing mismatched regions.

The DNA polymerase mutant of *E. coli* is unusually sensitive to ultraviolet light, as would be expected were DNA polymerase concerned with the repair of the damage wrought by this irradiation. On page 708, Boyle, Paterson and Setlow report the reason for this sensitivity. They find that the mutant is not defective in its ability to excise thymine dimers. But it does have an abnormally active exonuclease activity which extensively degrades the DNA of mutant cells after ultraviolet irradiation. If this is a result of the mutation to DNA polymerase, it may be that the mutant enzyme is no longer able to synthesize DNA *in vitro*, but retains an ability to degrade DNA *in vivo*, although with altered characteristics.

Trgovčevic and Kucan suggest (page 752) that DNA polymerase may be concerned with the degradation of DNA *in vivo*. Irradiation with X-rays or gamma-rays introduces internucleotide chain breaks into the DNA of *E. coli*, and after this the bacterial DNA is degraded quite considerably. They find that the products of degradation induced by gamma-rays are such as to result from an enzyme action which is exercised in *E. coli* only by DNA polymerase. This invites another experiment with the DNA polymerase mutant; it would be interesting to see whether the characteristics of this degradation are affected by the mutation. It seems that definition of which of its many postulated roles DNA polymerase actually fulfils *in vivo* must await a more complete investigation of the precise nature of the polymerase mutation.

ENZYMES

Counting Sites

from our Molecular Biology Correspondent

ENZYMES of which the molecular weights and number of subunits have been in dispute are legion. Particular frustration and bad temper seem to result when the number of subunits determined by molecular weight measurements disagrees with the apparent number of active sites. An interesting case has now been resolved by Mann *et al.* (*Biochemistry*, **9**, 1348; 1970). This is human transferrin, an iron-binding protein present in serum. It is accepted that the molecule has two iron-binding sites with identical characteristics. Reported molecular weights vary between 68,000 and 93,000, and there has also been a choice between the views that the protein consists of a single chain, and that it can be caused to dissociate into two subunits.

The new results give a molecular weight by sedimentation equilibrium of 77,000, which agrees with two out of the range of earlier measurements. The fully denatured, reduced protein examined in guanidine hydrochloride solution has a similar molecular weight, and two other methods involving complete denaturation and dissociation of subunits likewise lead to a value in the 70–80,000 range. It thus appears that transferrin represents an unusual case of a single polypeptide chain possessing two identical functional sites. In terms of precedent this is so unexpected that one is immediately forced to consider whether the protein may nevertheless in reality not consist of two subunits, which are covalently fused. Mann *et al.* prepared tryptic fingerprints, and counted the number of peptides. Subjective as this procedure is apt to be, it still seems that there are altogether too few fragments for the number of trypsin-labile bonds (one for each lysine and arginine) expected on the basis of amino-acid composition. Thus some fifty-four spots can be discerned, whereas seventy-six are expected, and specific staining for tyrosine, tryptophan and histidine indicated that peptides containing these residues were also present in only half to two-thirds of the expected number. The evidence is circumstantial, for with such a large number of fragments there can be no assurance. that all are resolved, but the results are at least consistent with the conjecture hazarded by Mann *et al.* that transferrin may indeed consist of two identical polypeptide segments that have insome way grown together It may be recalled that covalent association between two subunits of β-galactosidase in wild-type *E. coli* was postulated recently by Goldberg (*J. Mol. Biol.*, **46**, 441; 1969), the covalent link between them being reportedly absent in a mutant.

A protein long the centre of bitter wrangles is myosin. It is now established that it consists of two principal chains and some additional small associated chains. If any lingering doubts remained about the presence of two active sites in myosin, Murphy and Morales (*Biochemistry*, **9**, 1528; 1970) have dispelled them still further: using an ATP derivative with a built-in chromophore that absorbs in the near-ultraviolet, they measure the number of binding sites from the magnitude of the transient absorbance change that accompanies the introduction of the substrate into the protein solution, and find a value of close to 2.

But the greater interest in this work is that the new chromophore contains a thiol group, which, when the *p*H is raised above 8, will react with a cysteine side chain at or near the active site. The enzymatic activity is then inhibited, and is regenerated only when the disulphide bond which has been formed is broken by addition of excess of an added thiol. Two moles of the chromophore are then again released per mole of myosin. When the light chains of the labelled myosin are stripped off, the label comes with them. This is an agreeable result, for it strongly supports earlier suggestions that a low molecular weight species on the myosin carries or at least closely associates with the ATPase sites.

NUCLEIC ACIDS

Searching for Messengers

from our Cell Biology Correspondent

IDENTIFYING messenger RNAs or their precursors in mammalian cell nuclei is proving as hard as picking out a handful of needles from a haystack. The chief problem is that mammalian nuclei contain a heterogeneous collection of high molecular weight RNAs which have some of the characters of messengers. Apart from their large size and heterogeneity these RNAs undergo rapid turnover in the nucleus; apparently the molecules never migrate to the cytoplasm and never participate in protein synthesis. As a result, in pulse labelling experiments the heterogeneous nuclear RNAs form an effective screen obscuring the detection of the messengers.

A few weeks ago (*Nature*, **226**, 215; 1970) I mentioned the experiments of Darnell and his collaborators which are at least compatible with the idea that in HeLa cells a small fraction of the total heterogeneous nuclear RNAs are precursors of cytoplasmic mRNAs which escape destruction in the nucleus and undergo maturation by cleavage before migrating to the cytoplasm. This hypothesis, attractive if only because it suggests a function for the nuclear heterogeneous RNAs, implies that the nuclear precursors of mRNAs are considerably larger than the mRNAs to which they give rise. Unwanted sequences must therefore be chopped from the molecule as it matures, just as the precursor of ribosomal RNA is cleaved to yield the mature RNA.

Clearly the best way to test this suggestion is to look for the precursor of a particular mRNA, but in mammalian cells that is almost impossible. Lindberg and Darnell (*Proc. US Nat. Acad. Sci.*, **65**, 1089; 1970) have therefore turned to mouse 3T3 cells transformed by SV40 virus which have the viral genome stably incorporated and make SV40 specific RNAs. The amount of viral specific RNA in the nucleus and cytoplasm of the transformed cells is very small but at least it can be assayed.

Using pulse labelling and DNA/RNA hybridization, Lindberg and Darnell find that the nuclear RNA which hybridizes with SV40 DNA is larger (molecular weights range from $2\text{-}4\times10^6$ daltons) than the cytoplasmic RNA which hybridizes (molecular weight about $1{\cdot}7\times10^6$). Of course, experiments of this sort do not prove that large nuclear molecules are precursors of the small cytoplasmic molecules but at least they do not preclude that possibility. The other interesting point to emerge is that the largest nuclear RNAs containing SV40 sequences are larger than the SV40 genome. Either these RNAs contain some cellular as well as viral sequences or they may be the products of transcription of at least two SV40 genomes in tandem. This latter alternative is feasible because cells transformed with SV40 are believed to contain some twenty to sixty copies of the virus, which may all be in tandem.

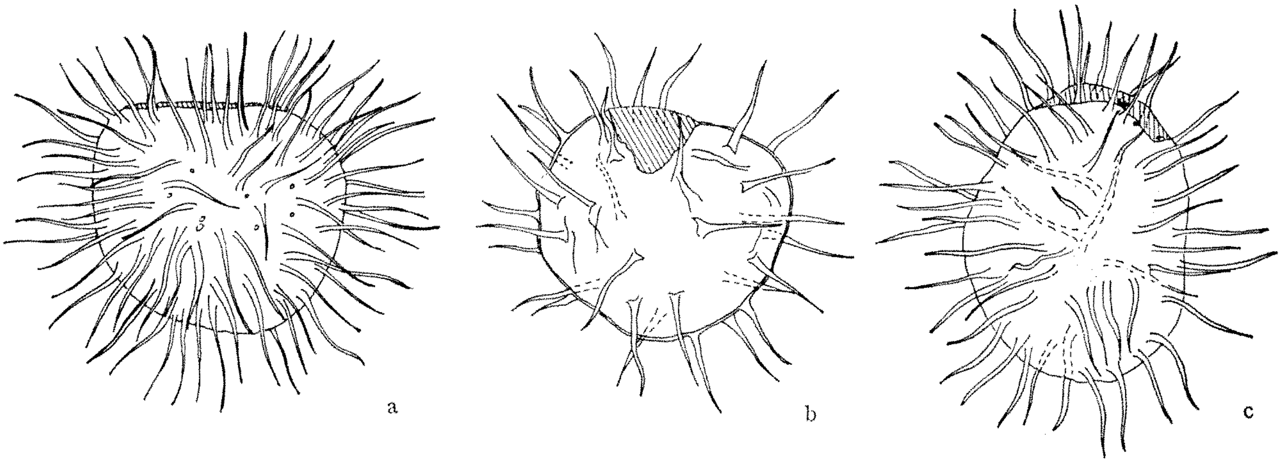
It will be particularly interesting if Darnell's group finds the first alternative to be correct, but even if all the sequences in the largest nuclear RNAs prove to be viral that will strengthen the case for asserting that viral genomes can occur in tandem in transformed cells.

The synthesis of SV40 mRNA in transformed 3T3 cells takes place against a background of synthesis of 3T3 mRNA. Cheevers and Sheinin (*Biochim. Biophys. Acta*, **204**, 449; 1970) have recently analysed the metabolic stability of messengers associated with polysomes in these cells. Using very low concentrations of actinomycin *D* to block synthesis of ribosomal RNA while leaving mRNA synthesis unaffected, they find the kinetics of incorporation of uridine indicate that the cells contain at least two classes of mRNA. One is predominant but ephemeral, with a lifetime of about 2 h, while the other is stable for at least 6 h. The significance of these differences for the regulation of gene expression is, needless to say, obscure.

MICROPALAEONTOLOGY

Finds from the Clay

Two new genera and twelve new species of fossil dinoflagellates have been yielded by exposures of Kimmeridge Clay in England, Scotland and France. They have been described by G. V. Gitmez together with many other species of these unicellular organisms, living examples of which botanists and zoologists claim as both algae and protozoa because of their apparently intermediate characteristics (*Bull. Brit. Mus.* (*Nat. Hist.*), **18**, No. 7; 1970). All that remains of the Upper Jurassic species preserved in the Kimmeridge Clay are the hard outer coverings produced by the soft bodies. The variety of form among these structures provides palaeontologists with scope for a great deal of taxonomic activity, such as the description of *Cleistosphaeridium polyacanthum* (*a* in the illustration, ×1,400). This new species was found at Ringstead Bay in Dorset, and Gitmez says that it is morphologically intermediate between *C. ehrenbergi* (*b*, ×1,280) and *C. polytrichum* (*c*, ×1,280).



NATURAL HISTORY

Running a Museum

The work of the modern natural history museum is, according to Dr Ernst Mayr, more relevant to today's environmental problems than most of the work carried out in experimental laboratories. Writing in his last annual report as director of the Museum of Comparative Zoology at Harvard University, Mayr emphasizes the need for interdisciplinary research and teaching, such as he has been encouraging at Harvard for the past eight years. All aspects of the living animal and its evolution come into the museum's scope—ecology, behaviour, anatomy, physiology, biochemistry and genetics, as well as the more traditional museum activities of taxonomy and the maintenance of collections. Field expeditions, of course, still play an important part in the museum's life, and staff and students ventured far and wide in 1969, returning the richer for knowing more about the evolution of early hominids in East Africa, the chromosome patterns of the iguanid lizard, *Sceloporus*, in Mexico, the adaptive radiation of penguins, and the coadaptations of fruit eating birds and the plants they eat in Costa Rica.

Many of the taxonomic studies in the museum have important implications outside their own specialized fields. Dr R. W. Matthews, for example, has been revising a little-known genus of wasps called *Spathius* that parasitizes bark beetles, important economic pests of conifers. In the past, it has been difficult to identify these wasps accurately, but Matthews has been able to work out keys for their identification and has recorded the host range of each species. It seems that some of the wasps attack several different species of bark beetle and other wood infesting insects, and rather than being host specific they are influenced by the type of tree which the beetles attack. This research may provide some clues for biological control of the beetles.

Correct classification of animals and plants is essential to comparative studies such as those carried out at Harvard, so that it is important that the basic unit of classification, the species, is well defined and delimited. With all the sophisticated techniques at the fingertips of taxonomists today, it might be assumed that many previous classifications, some worked out well over a hundred years ago, would now be found to be faulty. This certainly does not seem to be the case for some groups. Mayr, in collaboration with Dr L. Short, of the American Museum of Natural History in New York, has found, for example, that there is little disagreement today about the 606 species of North American birds, even though most were first described in the eighteenth century. For molluscs, however, the story is rather different. Recent estimates of the number of living species of these animals range from 40,000 to 150,000, the most recent being 107,000. The reliability of these figures has been assessed by Dr K. J. Boss of the museum, who has analysed the most recent and thorough revisions of families and genera. He has found that each real species has been named at least five different times, with some freshwater and land forms being named two hundred times. Analyses of the faunal distribution of molluscs have confirmed that the total number of species is far smaller than is usually claimed, and Boss puts his estimate at about 50,000.

SEA FOODS

Prawn Farms on the Way

THE rearing of prawns on a commercial scale has become a possibility now that they have been successfully cultured from larval to adult stages at the Ministry of Agriculture, Fisheries and Food Experiment Station, Conway, Wales. J. R. M. Forster reports encouraging results of the first outdoor rearing trials which demonstrate the feasibility of using, on a larger scale, the experimental techniques worked out at Conway (*Fish. Invest.*, Series II, XXVI, No. 6; 1970).

Palaemon serratus, the prawn in question, had already been reared to the first juvenile stage (M. R. Reeve, *Fish Invest.*, Series II, XXVII; 1969), and Forster's task was to provide suitable culture conditions in which the various juvenile stages could moult and grow to adulthood. Experiments began in the laboratory with prawns in beakers and plastic buckets of aerated seawater, and later moved outside where tanks and plastic dustbins were brought into use.

Food requirements proved a problem. Newly metamorphosed juveniles fared best on live daily rations of the fairy shrimp *Artemia*, later being weaned on to prepared food consisting of chopped mussel, crab, shrimp and lugworm. After weaning, the young prawns grew best when given mixtures of prepared foods rather than a diet of pure mussel or shrimp, for which Forster can offer no explanation. Later juveniles, from about two weeks after metamorphosis, were less demanding, growing just as well on a single food as on mixtures.

The other great problem was cannibalism, which was the largest single cause of mortality in laboratory populations of juvenile prawns. Many freshly moulted, soft individuals were attacked and eaten by their hard-shelled companions. The prey could not be induced to hide in lengths of tubing, and so their fate depended only on their ability to escape from the predators. Cannibalism turned out to be related directly to population density, and there were good signs that increasing the floor space, in this case by placing horizontal slats in the tanks, decreased cannibalism.

The optimum temperature for survival and growth of prawns in culture seems to be between 20° and 24° C; at 18° C growth was generally retarded, although survival was good, and at 26° C growth was good but survival poor. Forster points out that this is a significant finding if commercial rearing of prawns is to be attempted in Britain, where temperatures in outdoor tanks reach 20° C only from June to early September. At other times of the year artificial heating would be necessary.

As far as light conditions are concerned, growth was best in total darkness but survival was reduced. There seems to be no advantage in continuous illumination at any of the intensities that have been tested, although it is apparently possible that continuous illumination below six lumens per square foot results in improved growth. The prawns did not seem to be affected by the turbidity of the water as long as it was aerated vigorously to maintain the concentration of dissolved oxygen.

Forster thinks that the techniques now developed for culturing prawns would probably be best used on a commercial scale for some species other than *Palaemon serratus*, which has some inherent handicaps, notably its failure to survive for more than a few days at temperatures below 4° C, and the small size of the males, which, at a maximum of 5 grams, do not reach an optimum commercial size. Although it may prove possible to solve the temperature problem by making use of warm water effluents from power stations, Forster feels that it would be worth looking for another species to culture in Britain.

ELECTRON MICROSCOPY

More Scope for Scanning

from a Correspondent

THE range of applications of scanning electron microscopy continues to grow fast, as delegates to a symposium on this topic learnt at the Illinois Institute of Technology in Chicago from April 28 to 30. Most contributions, however, dealt with applications of what can now be regarded as the conventional mode of operation of the scanning electron microscope, using secondary electrons emitted in the backwards direction to form the image. Applications in metallurgy, semiconductor electronics, materials science, biology and medicine are expanding at a great pace, but little of the work involved makes any general contribution to the method. How many more such specialist conferences will be justified before the method is regarded as established ?

As usual, the efforts of Professor Albert Crewe (University of Chicago) aroused a great deal of interest. He demonstrated a 10 Å resolution last year and claims something like 5 Å this year, in a transmission scanning electron microscope with a field emission source (described earlier in *Nature*, **226**, 213; 1970). This method has the advantage over conventional transmission electron microscopy that energy loss analysis can be conducted on the transmitted beam and that it is sensitive to differences in atomic number. It is possible to examine much thicker specimens than are used in a transmission electron microscope run at the same accelerating voltage, and a much higher contrast can be obtained with the Crewe method.

In the biological sphere, it was interesting to find that the value of using as low an accelerating voltage as will give the required resolution is becoming widely recognized. Mr A. N. Broers (IBM) showed that it is possible to achieve high resolution, certainly better than 100 Å, from a biological sample—in this case of bone crystals. A lively discussion followed the description by Mr W. C. Lane (Battelle Memorial Institute) of his environmental control stage which allegedly makes it possible to examine water drops in the scanning electron microscope. Even this was doubted and it was suggested that the surface of the drop might be a thin skin of ice. The usefulness of a freezing stage in the examination of frozen botanical specimens was demonstrated by Dr P. Echlin and others from the University of Cambridge.

It is surprising that, in a meeting devoted to the results of a method of microscopy with a great depth of focus, so little attention was paid to measurements made in these images. Simple magnification markers in images of rough surfaces serve practically no useful purpose and it is to be hoped that some alternative method of conveying approximate information about sizes, such as signifying the nominal width of the field, will soon be adopted.

EARTH'S MANTLE

Viscosity and Drift

from our Geomagnetism Correspondent

It is implicit in the theories of continental drift and sea floor spreading that at least the upper mantle of the Earth, though ostensibly solid, behaves in certain circumstances as a viscous fluid. The first application of viscous flow theory to the asthenosphere, in fact, owed nothing to continental drift but arose in calculations of the viscosity required to enable Fenno-Scandia to return to isostatic equilibrium after the removal of the most recent glaciation. Working along these lines, Haskell (*Physics*, **6**, 265; 1935) estimated the anelastic response of the upper mantle to applied stress in terms of a Newtonian fluid viscosity of the order of 10^{22} poises. Later, Crittenden (*J. Geophys. Res.*, **68**, 5517; 1963) derived a value of the order of 10^{21} poises from a similar study of the Lake Bonneville uplift.

These estimates were derived from application of viscous theory over comparatively localized areas of the Earth, and may or may not be valid over regions of continental or oceanic extent. The question thus arises as to whether the more modern concepts of global tectonic mobility can be used to calculate the viscosity on which they themselves depend. Cramer (*Science*, **167**, 1123; 1970), using a very simple model, has shown that they can and that, furthermore, the result turns out to be almost identical with the earlier results of Haskell and Crittenden.

The basis of Cramer's analysis is to assume that the decrease in amplitude of ocean bottom relief from the mid-Atlantic Ridge towards the continents arises from viscous creeping of the bottom features under gravitational stress. Examining an east–west profile across the mid-Atlantic Ridge at 25° N, and assuming a sea floor spreading rate of 2 cm yr^{-1}, Cramer obtained a mantle viscosity of between 1·5 and $3{\cdot}9\times10^{22}$ poises with a most probable value of $2{\cdot}1\times10^{22}$ poises. A similar analysis of a second profile at 28° 40′ S led to an apparent change in viscosity at some time in the past. Up to a point 160 km to the west of the Ridge the calculated viscosity was $4{\cdot}6\times10^{22}$ poises whereas beyond 160 km it turned out to be $8{\cdot}2\times10^{22}$ poises.

Whether this discontinuity in viscosity is real is a moot point. Clearly much depends on the accuracy of the assumed spreading rate; and an apparent change in viscosity could equally well be due to a change in spreading rate at the 160 km point. Indeed, there is already evidence that the spreading rate has decreased along some portions of the mid-Atlantic Ridge. The actual spreading rates deduced by Heirtzler *et al.* (*J. Geophys. Res.*, **73**, 2119; 1968) are 1·3 to 1·4 cm yr^{-1} at 25° N and 2·0 cm yr^{-1} at 28° 40′ S. The use of these values would tend to make the viscosity values converge, bringing them within the error of least squares analysis.

The essential result, however, is that in spite of the large difference in the horizontal dimensions of Fenno-Scandia and Lake Bonneville, on the one hand, and the Atlantic Ocean, on the other, a very simple model for the ocean floor produces values for mantle viscosity remarkably consistent with the earlier results of Haskell and Crittenden.

MAGNESIUM ISOTOPES

Arcturus Like Solar System

from our Cosmology Correspondent

By studying the magnesium hydride bands in solar and stellar spectra the relative abundances of the magnesium isotopes can be determined fairly accurately. The terrestrial and meteoritic abundance ratios for ^{24}Mg : ^{25}Mg : ^{26}Mg are known to be 80 : 10 : 10, and the solar abundance ratios were thought to be roughly comparable, until in a study of sunspot spectra D. Branch found ratios of 60 : 20 : 20 (*Astrophys. J.*, **159**, 39; 1970). Branch has joined forces recently with R. A. Bell to measure these isotope ratios for the star Arcturus, a *K* giant.

This analysis has been carried out using a computed model in which the abundance ratios, Doppler velocity, atmospheric temperature and other physical parameters of the atmosphere can be varied to produce theoretical line spectra, a boundary temperature of 3,360 K producing the best fit with the observed colours for

Arcturus. R. Griffin's recent *Photometric Atlas of the Spectrum of Arcturus* provides the required observational detail for comparison with these computed spectra, from which Bell and Branch find that the observations are consistent with ratios of 80 : 10 : 10, like those found on Earth and differing considerably from the revised values for the Sun (*Astrophys. Lett.*, **5**, 203; 1970). It is certainly clear that both 100 : 0 : 0 and 60 : 20 : 20 can be ruled out as possible ratios for the magnesium isotopes in Arcturus and this must cause some doubt as to whether Branch's earlier result can be taken as typical of the whole Sun. If the magnesium isotopes are present in the same proportions for the whole solar system and in other stars, we have a useful insight into the formation and evolution of stars and planets; the 80 : 10 : 10 ratios would certainly seem more reasonable for the Sun on the basis of theoretical nucleo-synthesis rates, so that the overall inference of these calculations must be that general conclusions based on the spectra of sunspots should be treated with great caution.

SPECTROSCOPY

Power of Photon Echoes

An ingenious way of measuring hyperfine structure has been suggested which uses what is known as the photon echo technique. This involves bombarding atoms with two pulses of light separated by a short time interval and retrieving echo frequencies of two closely spaced energy levels which can be made to beat together. A. I. Alekseyev (*Phys. Lett.*, **31**, 495; 1970) has shown that by making the frequency of the incoming light quite similar to those of the energy levels in question it is possible to resolve quite remarkably close energy levels in the atoms, and he has suggested some ways of testing this.

The important feature of the technique seems to be that the frequencies picked up in the echo are independent of the initial input frequency. This happens because of the way in which the electrons are excited and relax between the two closely spaced input pulses. The two outgoing waves then combine to produce beats with a frequency equal simply to the difference between those of the atomic energy levels in question.

Although the photon echo method has been used to study chromium ions in ruby and other similar systems Alekseyev's application seems to be a quite new suggestion. There are already, of course, a variety of techniques for measuring hyperfine energy levels including conventional microwave or radio spectroscopy. But both the precision claimed for the photon echo method and the novelty of the interactions involved lend particular interest to demonstrating these ideas in an actual experiment.

MARS

Mariner Spots Phobos

by our Astronomy Correspondent

One of the two satellites of Mars has been found on three of the more than two hundred television pictures of Mars taken by Mariners 6 and 7 last year, and on one of the pictures the image of the satellite, Phobos, is large enough to provide a valuable estimate of its size. Rather surprisingly, Bradford A. Smith of the New Mexico State University, a member of the Mariner evaluation team, reports that Phobos is decidedly elliptical in shape (*Science*, **168**, 828; 1970). Although this suggests that Phobos is asteroidal in origin, it raises once again the awkward problems in accounting for the orbit of Phobos which is equatorial and only 3,750 miles from the surface of the planet. So far there is no evidence that either of the Mariners recorded the second Martian satellite, Deimos, which is roughly the same size as Phobos but orbits at about six Mars radii from the surface. But there are a further three pictures on which Phobos has been tentatively identified, and Smith emphasizes that his analysis is based on only the preliminary processing of the Mariner television experiment.

The essential result reported by Smith is that Phobos is elongated in the direction of its orbital motion, measuring fourteen miles in diameter at its equator and eleven miles at the poles. There is no information about the third dimension, of course. Smith also estimates that Phobos has an albedo of only 0·065, making it the darkest body in the solar system. Up to now Mercury with an albedo of 0·100 has been held to have this title.

The problems which the ellipticity raises have been discussed most recently by G. A. Wilkins (*Istituto Nazionale di Alta Matematica, Symposia Mathematica*, **3**; 1970). It is difficult to see how a captured asteroid can be constrained to move in the equatorial plane like both Phobos and Deimos, yet there seems to be no reason why asteroids should be captured directly into equatorial orbits. On the other hand, if the satellites were formed *in situ* at roughly the same time as the formation of Mars, by accretion in a cloud of dust, then an equatorial orbit seems more likely. This is because particles orbiting the planet in any plane but the equatorial plane are easily dispersed. Another drawback to the capture hypothesis is that any mechanism which is strong enough to force Deimos into its present nearly circular, equatorial orbit will be so strong as to make Phobos collide with Mars within a short interval of time.

This is why Wilkins seems to favour the accretion hypothesis, but the asteroidal shape of Phobos revealed by Mariner 7 must now be a serious obstacle. There is no reason why a moon formed by accretion should be anything but spherical, but the asteroids are known to be often irregular in shape. Thus the Mariner photograph has exacerbated a problem which has been a headache in orbital dynamics for years. The discovery makes even more urgent the task of improving knowledge of the orbits of Phobos and Deimos which should add to the information about how the system has evolved, as well as saying something about the shape of Mars. One astronomer has even gone so far as to suggest the soft landing of a radio transmitter on Phobos, nicely illustrating the fixation that those dealing with orbital mechanics have on the Mars problem.

The low albedo that Smith has recorded will also require some explanation, but Smith's view is that it is because Phobos lacks the dusting of interplanetary particles which the Moon (albedo 0·115) and also feasibly Mars (0·154) and Mercury have. This is a natural outcome of the low escape velocity of a small body, and what is being seen is the dark colour underlying rock.

Nickel in Western Australia

by
REX T. PRIDER
Department of Geology,
University of Western Australia

Nickel ore deposits discovered in Archaean ultramafic greenstones and Tertiary laterites have resulted in frenzied ore search operations in Western Australia. This article outlines the geological background to the discoveries.

THE discovery of nickel deposits at Kambalda[1] in January 1966 has precipitated a feverish search by the world's major mineral exploration companies which rivals the gold rush of the early 1890s. Few stones remained unturned in the million square miles of Western Australia by the turn of the century, but the prospector of those days was interested only in gold. As a result, the rich nickel deposits discovered at Kambalda were overlooked, in spite of the occurrence of nickeliferous limonitic gossans in surface pits sunk in this area soon after the discovery of gold there in 1898.

Mineralization in Western Australia[2], with one exception, is confined to the Pre-Cambrian rocks which occupy more than a quarter of a million square miles. Primary nickel deposits occur in Archaean greenstone belts and secondary deposits occur in Tertiary laterites. The geological background to the occurrence of nickel in Western Australia therefore focuses on the earliest (Archaean) and latest (Tertiary to Recent) parts of the geological record.

Archaean of Western Australia

Archaean rocks occupy approximately 300,000 square miles of Western Australia forming the Yilgarn and Pilbara Blocks, and possibly part of the Kimberley Block (Fig. 1). The geological sequence is similar in both cratons and resembles those of other Pre-Cambrian Shields, such as the Canadian, Indian and Southern African Shields[3]. These cratons consist largely of granitic gneisses with narrow older belts of metavolcanic and metasedimentary rocks and younger massive granite plutons[4].

In the Yilgarn Block, the oldest recognizable rocks are metavolcanic "greenstones" and interbedded metasedimentary "whitestones" of the Kalgoorlie–Yilgarn Succession. The Greenstone Phase of this succession consists predominantly of altered basaltic lavas, often pillow-structured indicative of submarine origin, with subordinate fragmental volcanics, and occasional thin interbedded layers of chemically deposited banded iron formation and jaspilite. The Whitestone Phase consists of clastic sediments (shales, sandstones and conglomerates) and acid volcanics. Recent work in the country between Norseman and Kalgoorlie[5,6] has established a stratigraphic succession consisting of repeated volcanic cycles, each varying from basic volcanics upwards to acid volcanics and clastic sediments. Although these greenstones and whitestones are undoubtedly the oldest rocks yet found in the Australian Shield, they have obviously been erupted on to an earlier Earth crust which has nowhere been identified with certainty.

The interbedded basalts, acid volcanics and clastic sediments of the Kalgoorlie–Yilgarn Succession have been concordantly intruded by ultrabasic magma now represented largely by serpentinites, the result of serpentinization of peridotitic rocks. These intrusive serpentinites are probably Alpine-type serpentinites belonging to a late stage in the geosynclinal development represented by the earlier basalts and sediments which were strongly folded and intruded by the serpentinites. It is these altered intrusive ultramafics which seem to be particularly significant so far as the nickel mineralization is concerned. There are also layered, gravity-differentiated, basic igneous stratiform complexes which have been less metamorphosed and are characterized by an abundance of primary unserpentinized minerals, such as olivine and pyroxene. They vary from ultramafic rocks, such as various peridotites and pyroxenites in the lower parts to mafic rocks, such as gabbros and norites, near the top[7,8]. The ultramafic parts of these intrusive stratiform complexes may also be significant so far as nickel mineralization is concerned. Indeed, these complexes are comparable, although much smaller, with the Giles Complex of Central Australia on which the Wingelinna nickel deposits developed by lateritization processes during Tertiary times.

Throughout the Yilgarn Block the Kalgoorlie–Yilgarn greenstones and whitestones and associated serpentinites and stratiform basic complexes have been isoclinally folded on NNW-trending axes and contemporaneously metamorphosed and granitized. They now occur as elongated, synformal, steeply dipping remnants in a vast

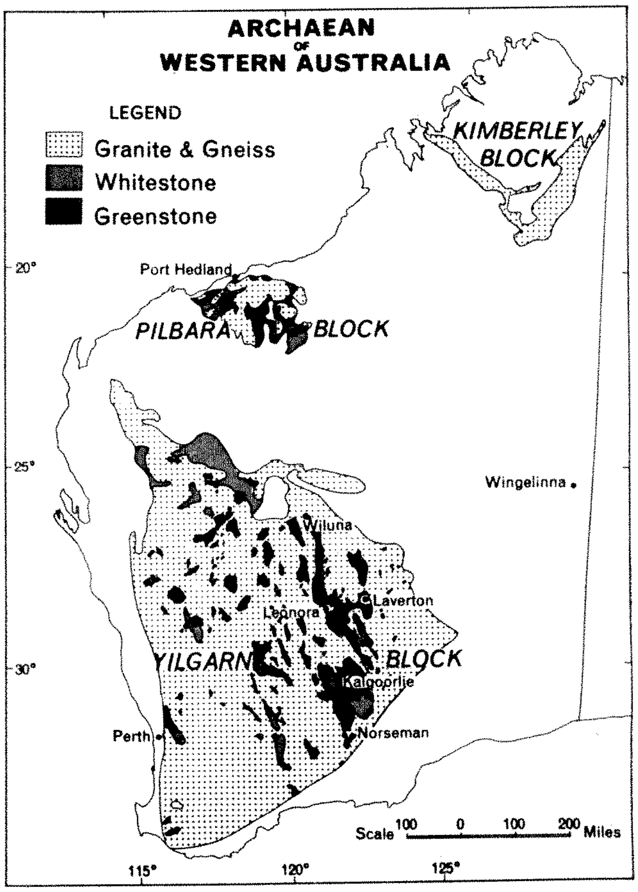


Fig. 1. Archaean blocks of Western Australia, showing "greenstone" belts.

expanse of granitic gneiss, which has resulted from granite intrusion and granitization of the Kalgoorlie–Yilgarn Succession (as evidenced by relict stratigraphy in the form of lenses of resistant beds, such as jaspilite). The gneissic foliation of the granitic gneisses conforms to the structure of the folded and metamorphosed greenstones and whitestones. The metamorphic grade of the Kalgoorlie–Yilgarn rocks seems to be a function of their proximity to the enveloping granitic gneiss[9]. Thus, at Kalgoorlie, which is centrally placed in the largest of these Kalgoorlie–Yilgarn remnants, the rocks have been subjected to greenschist facies metamorphism and retain much of their original structure and texture, the basalts being uralitized or chloritized, the ultramafics (peridotites and related rocks) being serpentinized, and the sediments not metamorphosed sufficiently to obscure their original clastic textures. In the marginal parts of the greenstone–whitestone inliers and in narrow greenstone belts the original basalts have been more highly metamorphosed to plagioclase–hornblende schists, the ultramafics to talc–tremolite and tremolite–chlorite schists, and the sediments to micaceous schists and quartzites.

The folded Kalgoorlie–Yilgarn Succession was intruded by discordant granites in late-Archaean times (about 2,615 million years ago). These granites, which are either homogeneous and medium to fine grained or coarse porphyritic and flow-banded in the marginal parts, tend to occur in structurally controlled elongated batholiths, elongated in a general north–south direction.

All the previously mentioned Archaean rocks in the country between Laverton and Norseman are intruded by east–west basic dykes (the Widgiemooltha Dyke Suite), the largest of which can be traced for 200 km and varies in size up to 3 km wide. These dykes have been radiogenically aged at 2,420 million years. Like the stratiform layered intrusions, they are also magmatically differentiated into ultramafic pyroxenites and mafic norites, the ultramafics of which may be of interest so far as the occurrence of nickel is concerned.

The Archaean of the Pilbara Block[2] resembles that of the Yilgarn Block in all but structure. It consists of folded metamorphosed greenstones and associated metajaspilites of the Warrawoona Succession and overlying sediments of the Mosquito Creek Succession, all intruded by a granitic complex. The style of folding differs from the NNW-trending structure of the Yilgarn Block insofar as there is no consistent trend, the tightly folded Warrawoona–Mosquito Creek rocks seeming to wrap around the larger granitic masses.

Archaean Nickel Deposits

The nickel finds made so far (except the lateritic nickel deposits of Wingelinna) are confined to the Archaean greenstones of the Norseman–Laverton–Wiluna Belt (Fig. 2). Other than in company reports, published information is available only about the initial discovery at Kambalda[1], 35 miles south of Kalgoorlie. Kambalda is situated in the same greenstone belt as Kalgoorlie, where the stratigraphic succession of a conformable sequence is as shown in Table 1. The Hannans Lake Serpentinite, an unlayered homogeneous intrusive outcropping south of Kalgoorlie, is a dark green massive serpentinite derived from a peridotite fine to medium grained olivine with interstitial pyroxene. It is interesting since the nickel sulphide ore bodies at Kambalda occur in a similar rock. But because of the intense isoclinal folding and accompanying strike faulting, along with paucity of outcrop, the relationship between the Hannans Lake Serpentinite and the Kambalda ultramafic has not yet been established.

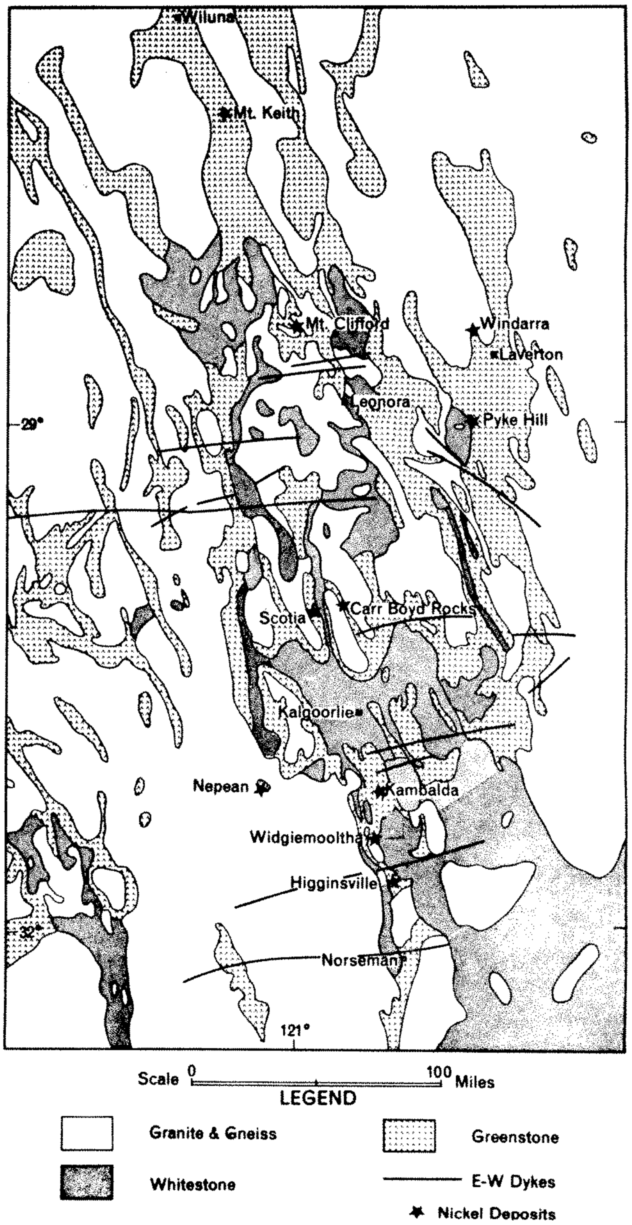

Fig. 2. Nickel deposits of the Norseman–Laverton–Wiluna "greenstone" belt (geology after Geological Survey of Western Australia, 1966).

The Kambalda nickel sulphide ore bodies are associated with a sill-like ultramafic body which lies more or less conformably between two metabasalts which contain some pillow structures. The ultramafic is a layered intrusion consisting essentially of varying amounts of serpen-

Table 1. STRATIGRAPHIC SUCCESSION AT KALGOORLIE (AFTER WOODALL[10])

Rock unit	Thickness (feet)	Lithology
Black Flag Beds	10,000	Acid to intermediate lavas and pyroclastics, overlain by sandstone, shale, slate and quartzite
Golden Mile Dolerite	1,000–3,000	Sill of meta-quartz dolerite
Paringa Basalt	1,000–3,000	Metabasalt (in part, pillow lavas)
Williamstown Dolerite	500–1,000	Sill of metadolerite transitional to meta-quartz dolerite near top and hornblendite [= metapyroxenite] near base
Kapai Slate	10	Graphitic slate
Devon Consols Basalt	200– 500	Metabasalt (pillow lavas)
Hannans Lake Serpentinite	1,000–3,000	Massive serpentinite

tine, talc, chlorite, amphibole and carbonate. Shale and banded chert present in the succession are prominent on the upper and lower surfaces of the ultramafic, and discontinuous but conformable chert bands, up to 50 feet thick, also occur within the ultramafic, indicating possible successive intrusions of ultrabasic magma. It is noteworthy that these sedimentary bands contain up to 50 per cent of iron sulphide, mostly in the form of pyrrhotite (Fe_7S_8). The geological structure is a dome, elongated in a NNW direction parallel to the regional strike, with the flanks dipping 45° to the east and west. Irregular stock-like bodies and flat-dipping dykes of porphyry are intrusive into all formations, including the nickel sulphide ore bodies. Most of the nickel sulphide mineralization occurs at the basal contact of the altered ultramafic with the underlying metabasalts, but a significant amount lies at higher stratigraphic levels within the ultramafic. The ore bodies are pyrrhotite–pentlandite associations with minor pyrite and chalcopyrite, and consist of a lower banded sulphide zone consisting entirely of sulphide minerals and an upper disseminated sulphide zone consisting of approximately equal amounts of sulphides and silicates and variable amounts of carbonate minerals[1].

Nickel deposits have been discovered at several other localities in the Norseman–Laverton greenstone belt (Fig. 2)—near Higginsville and Widgiemooltha south of Kambalda, at Scotia, Carr Boyd Rocks, Pyke Hill and Mount Clifford between Kalgoorlie and Laverton, and at Windarra and Mount Keith north of Laverton. All, with the exception of Pyke Hill (which seems to be the result of weathering of a nickeliferous serpentinite), are sulphide deposits, and all are associated with ultramafic intrusions and their metamorphosed derivatives, such as serpentinites and talc–tremolite schists. The most glamorized of these discoveries is the Windarra find, 15 miles north-west of Laverton on the property held by Poseidon N.L.

Nickel sulphide ores were discovered at Mount Windarra in September 1969 at the contact between an altered ultramafic (talc or talc–carbonate rock) and metasedimentary banded iron or jaspilite formation. This banded iron formation is exposed discontinuously along a low ridge for about 7 miles and there are occasional small outcrops of ultramafic rocks immediately adjacent to it on the east side. The contact strikes NNW but, because of the intense folding, is sinuous and dips steeply (80°–90°) to the east. Near the southern end of the outcrop area the dip flattens to 50° east. The Windarra ridge is on the east limb of a south-plunging anticline which, to the south, is completely covered by a thick alluvium layer. Part of the outcrop of the proved nickel sulphide body has been obscured by drift sand up to 30 feet deep which has accumulated against the Windarra ridge. The Windarra deposits, like the contact deposits at Kambalda, occur at the base of an ultramafic layer, but they differ from others in that banded iron formation (metajaspilite) rather than metabasalt forms the other wall. Nonetheless, it is interesting that banded ferruginous cherts, often with a high content of iron sulphide, occur in the associated country rocks at most deposits. This suggests that the sulphides of the chemically deposited sediments interbedded with the basaltic lavas were the source of the sulphur responsible for collecting nickel and copper from the later basic magma intrusions, as suggested by the sulphurization hypothesis of Naldrett[11], followed by the gravity separation of nickeliferous sulphides in the still-molten magma to form sulphide accumulations at the bottom of these intrusions.

It seems necessary, therefore, for the formation of these nickel ore deposits to have not only nickel-bearing ultrabasic intrusions, but sulphur-bearing country rocks such as pyritic or marcasitic sediments like the jaspilites, which are commonly associated with the submarine basalts of the early Archaean. But although some of the nickel ore bodies have been uncovered by mining operations, their mode of origin is still unknown.

Significance of Tertiary to Recent Land Surface

The southern half of Western Australia is an old, slightly dissected, lateritized land surface[12] dating from the middle or late Tertiary. The monotonous topography, characterized by long narrow salt lakes, elongated parallel to the regional structure, is relieved only by low ridges elongated in the same NNW direction, where resistant rocks such as jaspilites project above the general level. The lateritized surface is covered either by wind-transported sands, laterite, the completely weathered sub-laterite zone which extends to depths of the order of several hundred feet below the indurated laterite, or by Recent alluvial deposits resulting from sheet flood deposition in areas of arid erosion. It is this old land surface, with its highly weathered and lateritized cover, that has made mineral exploration in this country so difficult. The major gold mining centres of Western Australia are situated on ridges which lie near the laterite level, for only here could the prospector see the underlying rocks. The thick weathered cover and overlying alluvium and drift sand pose much the same problem to the present-day prospector, armed though he is with geochemical and geophysical techniques. As with the earlier gold discoveries in Western Australia, the most significant nickel finds, such as at Kambalda and Windarra, have been made in areas of relatively marked topographic relief, where the laterite cover is absent and the soils are residual in nature.

Lateritic nickel deposits occur at Wingelinna near the border of Western Australia with South Australia. Here the Giles Complex of mafic and ultramafic igneous rocks of Middle Proterozoic age has been lateritized, and secondary concentration of nickel has occurred along narrow zones representing infolded ultramafic layers along which the ultramafic rocks have been very deeply weathered. The Giles Complex rocks are deficient in sulphide minerals and the Wingelinna nickel deposits differ markedly from the sulphide mineralization of the Norseman–Laverton greenstone belt, with the possible exception of the Pyke Hill deposits, which have resulted from the weathering of nickeliferous serpentinites.

Because of the topography, the weathered nature of the country and the extensive alluvial cover, a small fraction only of the potentially nickeliferous areas (the "greenstone" belts) has yet been prospected for nickel.

Meteorology and the Clean Air Act

by
J. H. BRAZELL
Meteorological Office,
Bracknell,
Berkshire

Since 1956 there has been a steady improvement in visibility in town and country in Britain, which can only be attributed to the decrease in the amount of smoke in the air. The Clean Air Act seems to have been the chief cause of this decrease.

THE problem of atmospheric pollution and its effect on the wellbeing of people living in towns and cities is not new; in Tudor times there was an outcry against burning coal in London, and in December 1671 the diarist John Evelyn[1] wrote of the "thickest and darkest fog ever known". During a foggy week in December 1873 the death rate in the Administrative County of London was 40 per cent above average, and there were similar increases during fogs in 1880 and 1892. The continued growth and spread of London during the first half of the twentieth century intensified and extended the menace of pollution; for example, the great fog of December 1873 hardly affected Croydon, but the fog in December 1952 resulted in a sharp increase in mortality in that town. This fog of December 1952 was estimated to have been responsible for 4,000 deaths in the County of London; during the week of fog, deaths from bronchitis increased about nine times and from pneumonia nearly four times. These were much greater increases than previously recorded in London fogs. As a consequence there was intensification of the campaign for smoke abatement and the Committee on Air Pollution was set up in July 1953. The eventual result was the passing of the Clean Air Act 1956, which gave local authorities powers to establish smoke control areas.

Fogs are natural phenomena and apart from reducing visibility they are fairly innocuous, although they can be troublesome to people with afflictions such as chronic chest complaints. Medical experience, however, leaves no doubt that dangerous and harmful conditions occur when pollution is present in natural fog in sufficient quantity to produce "smog". Smoke and other forms of pollution thicken and contaminate fog, and increase its persistence and frequency in several ways. They provide nuclei for the formation of liquid fog particles and, even if the air is not moist enough for condensation, the smoke alone may be sufficiently dense to reduce visibility below the fog limit, provided the vertical stability is great enough and the winds light enough to prevent dispersal. The smog cuts off sunshine, thereby retarding the natural processes of heating and evaporation which would disperse the fog. The weather factors most likely to be improved by application of the Clean Air Act were therefore visibility and, to a lesser extent, sunshine. This seems to have been borne out by studies of the temporal variation of visibility and fog frequency in many "black areas" and by some work on London sunshine.

Fog in Greater London

In 1964 I[2] compared the frequency of dense fog (visibility less than 55 yards) and thick fog (visibility less than 220 yards) in central London (Kingsway) and outer London (Heathrow and Kew) during 1947–1962 (Table 1).

Chandler's map[3] of the "percentage fog frequency in London 0900 GMT September 1936–March 1937" showed that the frequency was least in the suburbs, and increased towards the centre of the city. Table 1 indicates that this situation had been reversed even before the Clean Air Act of 1956. The low frequency of fog in the city centre compared with the outskirts is attributed chiefly to the greater urban heat effect in the centre, but the reduction of pollution in central London probably also played a part. Before and, to a greater extent, after the Second World War, development in central London resulted in the replacement of many old coal-fired houses by large blocks of offices or flats heated principally by smoke-free methods. These developments increased the urban heat effect, and the combination of increased environmental heat and decreased smoke led to a reduction of fog. As Table 1 shows, a comparison of figures for 1947–1954 with those for 1955–1962 shows that the decrease in the frequency of dense fog was substantially greater at Kingsway than at Heathrow or Kew. To a lesser extent this also applies to thick fog.

Investigation showed that the mean winter urban heat effect at Kingsway was about the same during the two eight year periods, and that 77 per cent of the observations of dense fog there during the whole sixteen years were associated with winds of only one knot or less, suggesting that on occasions of dense fog local pollution was much more important than pollution drifting from elsewhere. It is very unlikely that the difference between inner and outer London was due to any synoptic variation. Local authority records show that, in general, smoke control commenced earlier and progressed faster in the area around Kingsway than in the areas around Kew and Heathrow, and it is reasonable to assume that this was the principal cause of the marked decrease in the frequency of dense fog at Kingsway during 1955–1962.

Wiggett[4] found that the mean frequency of observations of visibility 440–1,090 yards at London (Heathrow) Airport decreased by nearly 40 per cent during 1946–1963, and that there was a smaller decrease in the middle visibility ranges—about 10 per cent for visibilities between 45 and 105 yards. But there was no significant trend for visibilities less than 45 yards; this agrees with my figures for dense fog at Heathrow (Table 1).

Wiggett suggested that the fogs causing visibility of 440 to 1,090 yards were chiefly smoke fogs, and that the decrease in frequency was due to a reduction in smoke pollution, while the fogs with smaller visibilities were water fogs. The latter, however, must have been contaminated

Table 1. AVERAGE ANNUAL NUMBER OF HOURS OF DENSE AND THICK FOG AT KINGSWAY, HEATHROW AND KEW DURING 1947–1954 AND 1955–1962

		1947–1954	1955–1962	Percentage decrease
Dense	Kingsway	27	13	52
	Heathrow	57	54	5
	Kew	95	73	23
Thick	Kingsway	68	52	24
	Heathrow	202	177	12
	Kew	241	189	22

Table 2. AVERAGE ANNUAL NUMBER OF HOURS OF DENSE AND THICK FOG AT KINGSWAY AND HEATHROW DURING 1947–54, 1955–62 AND 1963–69

		1947–1954 (8 years)	1955–1962 (8 years)	1963–1969 (7 years)	Per cent decrease 55–62 to 63–69
Dense	Kingsway	27	13	2	85
	Heathrow	57	54	18	67
Thick	Kingsway	68	52	15	71
	Heathrow	202	177	83	53

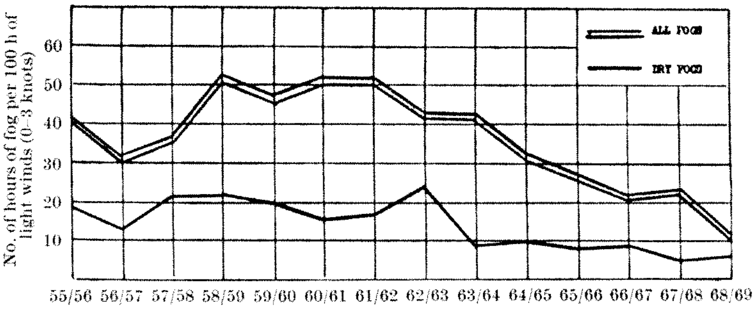

Fig. 1. Number of hours of fog (visibility < 1,000 m) and "dry" fog (visibility < 1,000 m and relative humidity < 95 per cent) per 100 h of light winds (0–3 knots) at Glasgow Airport in each winter from October 1955. (From *J. Nat. Soc. Clean Air*, **151**, 26; 1969.)

by smoke, and it may be that, although the reduction in pollution was sufficient to affect slight smoke fogs, it was not yet great enough to influence the frequency of dense fogs or smogs. Later observations tended to support this idea. Freeman[5], studying the frequency of thick fog, fog and mist at Heathrow during 1949–1967, confirmed the decrease in the frequency of fog[4] and also found that there had been a notable decrease in the frequency of visibilities less than 99 metres (about 108 yards) since about 1963. He concluded that the effects of the Clean Air Act (1956) in reducing smoke in the London area were chiefly responsible for the progressive decrease of fog at Heathrow.

If the figures for thick and dense fog at Kingsway and Heathrow are brought up to date (Table 2) it is clear that the marked improvement at Kingsway between 1947–1954 and 1955–1962 has continued and intensified, and that the same applies to Heathrow during 1963–1969. There seems little doubt that this is associated with the continued spread of smoke control measures under the Clean Air Act.

Manchester, Yorkshire and Glasgow

Atkins[6] has compared the frequencies of visibilities less than 220, 440, 1,100 and 2,200 yards at Manchester (Ringway) Airport during October to March in 1949–1954, 1955–1959 and 1960–1964, allowing for variations in the frequency of light winds (0, 1–3, 4–6 and 7–10 knots) from one period to the other. The frequency of each of the four classes of visibility during 1960–1964 was less than the corresponding frequencies during the two other periods. There seems to have been a noteworthy change about 1960, with light winds becoming less likely to be accompanied by poor visibility than before. It is reasonable to attribute this change to the operation of the Clean Air Act in north-west England. In 1960[7] the Ministry of Housing and Local Government estimated that about half the premises in Manchester would be in smoke control areas by the end of 1963.

Corfield and Newton[8] made a statistical analysis of visibilities in relation to wind direction at Finningley, an aerodrome to the east of the industrial part of the West Riding of Yorkshire, omitting occasions of precipitation. The wind directions, omitting calms, were grouped into 30 degree sectors to include sources of smoke pollution within 40 miles of Finningley. The chief sources of pollution are sector 235°–265° (Sheffield, Rotherham); sector 265°–295° (Doncaster, Barnsley, Mexborough, Huddersfield and Halifax); sector 295°–325° (Doncaster, Wakefield, Pontefract, Castleford, Dewsbury, Halifax, Bradford and Leeds).

Between 1958–1961 and 1962–1965 there was a marked decrease in the frequency of poor visibility (≤ 3,000 yards) and a marked increase in the frequency of good visibility (> 10 nautical miles) with winds in sectors 235°–265° and 265°–295°. But when winds were in the sector 295°–325°, although there was a decrease in the frequency of visibility ≤ 3,000 yards, there was a sharp increase in the frequency of visibility between 3,000 yards and 2½ nautical miles with little change in the frequency of other ranges. In connexion with these results, which can be linked with smoke control, it is interesting that Sheffield (235°–265°) is closer to Finningley than Leeds (295°–325°) and that, by 1965, almost 60 per cent of the buildings in Sheffield were under smoke control regulations compared with less than 20 per cent in Leeds, although the figure was about 40 per cent for Bradford which is still further away from Finningley. Although there are difficulties in interpreting the results, there is strong evidence that the improvement in visibility at Finningley is chiefly a consequence of smoke control.

In 1969, McKellar[9] examined the frequency of fog at Glasgow Airport during the winter (October–March) from 1955–1956 to 1968–1969, accepting the definition of fog as visibility less than 1,100 yards, and assuming "dry fog" to be fog with relative humidity less than 95 per cent. To allow for the variation in the frequency of light winds, results were expressed as the number of hours of fog per 100 hours of light winds (0–3 knots, Fig. 1). According to McKellar smoke control in some parts of the Glasgow area commenced in 1959 and the smoke control areas have been extending ever since. Fig. 1 shows a continuous reduction in the frequency of fog since 1961–1962 (1962–1963 for dry fog); smoothing the curves by taking pairs of winters, the average fog frequency for 1967–1968 and 1968–1969 was only about 17 hours per 100 hours of light winds compared with about 50 for 1959–1960 and 1960–1961. This is a reduction of about 66 per cent; the reduction for "dry fog" is about the same. Looking at occasions when the wind at the airport blew from the main areas of pollution (020°–100°) at speeds of 7–10 knots, and comparing visibilities during the winter of 1968–1969 with average conditions during the winters of 1958–1959 to 1961–1962 (Table 3), McKellar concluded that the visibility in Glasgow had improved significantly, presumably because of the operation of the Clean Air Act.

Fog in the United Kingdom

When Dinsdale[10] compared the frequency of fog at several rural and urban sites during 1947–1967 he demonstrated a general decline in fog frequencies in each case. He warned that changes in fog frequencies anywhere should be viewed against this background, and that the possibility of synoptic variations should not be overlooked. Fig. 2 shows the variation of the frequency of fog (visibility < 400 yards) at ten places in the United Kingdom during 1958–1967. The decrease in frequency at Elmdon (Birmingham Airport) is particularly outstanding. It is doubtful whether Dinsdale's assumption that stations such as Abingdon are "little affected by smoke" is correct. The aerodrome weather gazetteer for Abingdon states "the various smoke sources which have

Table 3. PERCENTAGE FREQUENCY OF VISIBILITY RANGES WITH WINDS OF 7–10 KNOTS FROM 020°–100° AT GLASGOW DURING THE WINTER (OCTOBER–MARCH)

Average	< 1,000 yds	1,000–1,999 yds	2,000–3,999 yds	4,000 yds–4 mls	4–8 mls	8–12 mls	12–20 mls	> 20 mls
Oct. 1958 to March 1962	4	35	40	21	0	0	0	0
Oct. 1968 to March 1969	0	3	43	26	20	8	0	0

noticeable effect on visibility at Abingdon lie in a wide sector which extends from north-west, through north and east to south" and "when light winds from NNW are maintained for a day or longer during the winter, smoke haze from the industrial areas around and beyond Birmingham becomes thick and persistent with little diurnal variation in visibility". It must be remembered that social changes such as blocks of flats instead of rows of houses, the spread of central heating and the increase in the number of working wives with a consequent decrease in all-day fires have all contributed to a diminution of smoke in many other towns and cities as well as in the "black areas". I do not suggest that drifting smoke would be thick enough to reduce visibility below 400 yards at all rural sites such as Abingdon, but it would tend to increase the persistence of natural fogs and any diminution of this smoke would therefore result in less frequent fog. Thus a diminution of smoke from "black or other areas" would result in a decrease in the frequency of fogs at both urban and rural sites. Although Dinsdale's caution is timely, I feel that his results support the thesis that the recent improvements in visibility are, to a large extent, due to smoke abatement.

Sunshine in Greater London

In 1969 Jenkins[11] noted the increase of sunshine in London during 1958–1967. He compared the increase in central London, as represented by Kingsway (this station was moved a quarter of a mile to Holborn in January 1965), with the recorded sunshine in the suburbs, as represented by Kew, and at a rural site near London, as represented by the Royal Horticultural Society's gardens at Wisley. Kew is about 9 miles WSW and Wisley about 21 miles SW of central London. The average monthly sunshine during the ten years 1958–1967 was expressed as a percentage of the thirty year average 1931–1960 (Fig. 3). The difference in amounts of sunshine at the three places was relatively small during the summer half year April to September, when domestic air pollution is always at a minimum. During the winter half year October to March, however, there was a marked increase in average sunshine at Kingsway, a much smaller increase at Kew and hardly any increase at all at Wisley. This fits in with the faster progress in smoke control in central London than in the suburbs. The average sunshine at Kingsway since 1958 during November to January has increased by about fifty per cent above the long term average (1931–1960) and average annual sunshine is now about the same at Kingsway, Kew and Wisley. This improvement is most likely associated with the decrease in smoke resulting from the Clean Air Act.

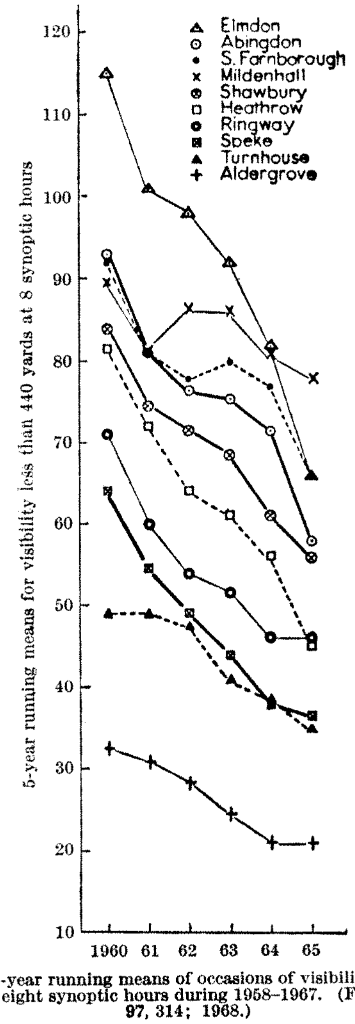

Fig. 2. Five-year running means of occasions of visibility less than 440 yards at the eight synoptic hours during 1958–1967. (From *Met. Mag.*, **97**, 314; 1968.)

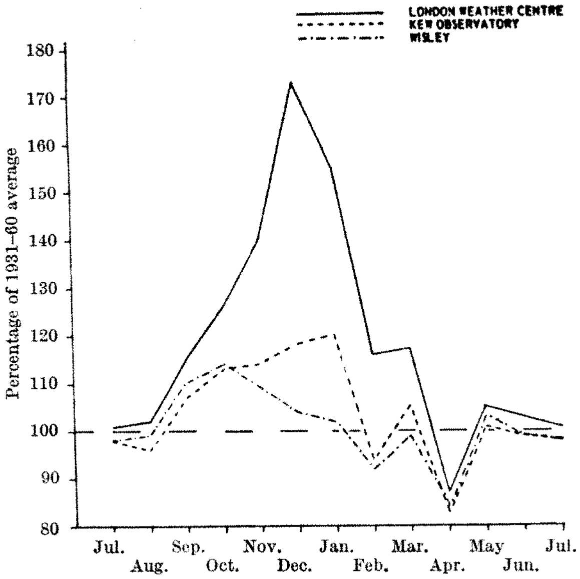

Fig. 3. Average monthly sunshine at the London Weather Centre, Kew Observatory and Wisley during 1958–1967 as a percentage of the average for 1931–1960. (From *Weather*, **24**, 2; 1969.)

Clearly there has been, during the last decade or so, a steady improvement in visibility at both urban and rural sites, particularly marked in some "black areas". In such areas the reduction in the frequency and intensity of fog has been dramatic. There has also been an outstanding increase in winter sunshine in central London during the same period. There seems little doubt that these improvements in weather are associated with smoke abatement, both voluntary and enforced, and it seems fairly certain that the Clean Air Act of 1956 is chiefly responsible for the dramatic improvement in certain towns and cities; the term "black area" no longer applies to these places.

Genes and Hereditary Characteristics

by
A. D. HERSHEY
Genetics Research Unit,
Carnegie Institution,
Cold Spring Harbor,
New York

This appraisal of ideas about genetic determination is based on Dr Hershey's report in the sixty-eighth *Year Book* of the Carnegie Institution of Washington, issued last February.

INFLUENTIAL ideas are always simple. Since natural phenomena need not be simple, we master them, if at all, by formulating simple ideas and exploring their limitations. The notion that genes determine the characteristics of biological individuals and species is exceptional among simple ideas: its limitations have consistently diminished with the passage of time. In this article I shall consider both the simplicity and the limitations of ideas about genetic determination.

The early students of heredity were forced to distinguish between the genetic constitution of an animal or plant (its genotype) and the expression of its genes in visible characters (its phenotype)[1]. The distinction is particularly clear in an individual that received dissimilar genes from its two parents: the dual genotype clearly gives rise to a single phenotype. But even an individual with a single set of genes has a phenotype that depends on its stage of development, environmental influences and accidental factors.

The notion that genotype controls phenotype is pure tautology in the typical breeding experiment in which genotype means differences between genotypes, and phenotype means differences between phenotypes. Mendel brought the tautology to light by showing that inheritance depends on unitary factors. Morgan and his students traced these factors to hypothetical genes at known locations in visible chromosomes and created the science of formal genetics[2]. The generality of Mendel's discovery can be summarized by saying that we know of no biological characters, including developmental patterns, that are immune to gene mutations. The importance of his discovery lay in showing that inheritance could be analysed.

Of necessity, formal genetics largely ignored questions about gene function. "As to the nature of 'genes' it is as yet of no value to propose any hypothesis; but that the notion 'gene' covers a reality is evident from Mendelism." This statement, quoted from Johannsen[1], sufficed pretty well for three decades. E. B. Wilson in his famous book expressed a more reckless opinion[3]. "No one . . . now conceives the chromosomes as exclusive agents of heredity. They may be considered as modifiers in a reaction system. . . . Chromosomes are to be regarded as *differential factors of heredity*, rather than central governing elements. . . ." The relation between genotype and phenotype for many years seemed infinitely complicated, as indeed it was in the prechemical era of genetics.

Help from *Neurospora*

In 1940 Beadle and Tatum turned new light on Mendel's unit factors when they described their first experiments with the bread mould *Neurospora*. This organism was unique at the time in permitting both genetic and nutritional experiments. With it Srb and Horowitz[4], for example, could show by mutational analysis that each biochemical step in the synthesis of the amino-acid arginine is the province of a single gene functioning in the production of a single enzyme. Results of this sort, epitomized in the phrase "one gene–one enzyme", obviously conflicted with what everybody knew: that the relation between genotype and phenotype was infinitely complicated. Chiefly because of this conflict, and partly too because the meaning of the phrase was not precisely defined, the new hypothesis met with strenuous opposition.

Actually, the hypothesis consisted of two parts: only one gene functions specifically in the synthesis of a single enzyme; and one gene functions specifically in the synthesis of only one enzyme (if any). Both parts were necessarily a little vague because the significance of the word "specifically" was not clarified for another decade or more. (We now say that one gene determines the amino-acid sequence of one enzyme.)

I do not suppose it is possible to assign a date to the eventual acceptance of the one gene–one enzyme hypothesis, but I remember clearly the Cold Spring Harbor Symposium of 1951 at which the controversy reached its climax. At that meeting Horowitz and Leupold[5] presented their paper entitled "Some Recent Studies bearing on the One Gene–One Enzyme Hypothesis", which would be better known today if it had been called "Confirmation of the One Gene–One Enzyme Hypothesis by the Use of Conditional Lethal Mutations". In the stormy discussion that followed I was unable to grasp the issues, but it was clear to me that nearly everyone was quarrelling with Beadle and Tatum, who were absent, and ignoring the results just presented.

Horowitz and Leupold offered rather subtle arguments in support of the hypothesis that only one gene functions "in a direct manner" in the synthesis of a single enzyme. They also showed that there are relatively few genes concerned with functions common to synthesis of proteins in general, and proposed that the immediate precursors of proteins are single amino-acids or their derivatives, not polypeptides. Their paper is historic both for cogency of argument and because it describes the first systematic use of temperature-sensitive mutants.

Chemical Genetics

In the context of the one gene–one enzyme hypothesis, subsequent developments were chiefly the discovery of two smaller classes of genes: regulator genes[6], the products of which in the well known examples are proteins interacting directly with DNA to interfere with the expression of other genes[7,8]; and genes in which the structures of ribosomal and transfer RNAs are encoded[9]. At present there are no clear indications that more classes remain to be discovered, although, of course, not all proteins determined by genes are properly called enzymes.

Genetics was a perfected theoretical discipline some time before chemical genetics was invented, and no real conflict between them was possible. (Read, for example, Wright's review[10], then Beadle's[11].) The initial aim of chemical genetics called for elucidation of the functional basis of the determination of phenotype by genotype. This aim has been achieved in large measure, largely through elucidation of the structure of DNA[12]. The chief element of surprise, I think, was the simplicity of the denouement, anticipated in part by Beadle and Tatum.

If the overall plan is simple, it ought to be possible to put it into a few words, which I attempt as follows. First, the genotype resides in DNA—more importantly, in the linear sequence of the four nucleotides in single DNA strands. Second, nucleotide sequences in single DNA strands are transcribable into complementary sequences according to simple one-to-one rules: the four bases form only two interstrand pairs, guanine–cytosine and adenine–thymine. This code or its equivalent is used for DNA replication, gene transcription, and synthesis of ribosomal and transfer RNAs. It also regulates the structure of typical double stranded DNA molecules.

Third, sequences in one of the two complementary strands, transcribed into messenger RNA, are translatable into amino-acid sequences in proteins according to a second code unrelated to the first. This is a non-overlapping triplet code (three bases per amino-acid) usually called the genetic code.

Fourth, the phenotype, to the extent that it is understood at all, depends on the structures of species-specific proteins, structures that depend in turn on linear sequences of amino-acids. This conclusion is a necessary inference from what is known of enzyme control of metabolism, on the one hand, and the nature of the genetic code, on the other. That amino-acid sequences determine protein structure might have been guessed years ago from the fact that thermal inactivation of enzymes is often reversible. It is now being proved by artificial synthesis of enzymes. Moreover, gross biological structure can be directly determined by subunit structure, as seen in the reconstitution of virus particles from their parts[13,14]. These successes demonstrate that three dimensional structures can be represented in one dimensional messages, and thus verify one of the most important implications of the Watson–Crick model of DNA—an implication that familiarity with human speech had scarcely prepared us for.

My summary is necessarily abstract. Perhaps I should mention one concrete fact. Rüst and Sinsheimer[15] have shown that either complementary strand of DNA from the phage φX can infect bacterial cells to give rise to identical viral progeny. Therefore the two strands contain the same genetic information: they encode the same genotype. If these two strands could be examined in detail, they would be seen to differ from each other in a systematic way: each adenine residue in one is matched by a thymine residue at the corresponding position in the other, and similarly for the pair guanine and cytosine. This is certain, even though nucleotide sequences cannot be read directly. How we know is fairly simple, too, but the evidence cannot be put into a few words.

What Critics Say

So far I have made what I consider to be factual statements. Perhaps the best way to assess my judgment in this matter is to look at the criticisms raised by people who see things differently. Carl Lindegren, a perceptive man with a brave disregard for the rules of debate, once pointed out that the city of Chicago existed for some time before it became dependent on electricity[16]. He inferred that if DNA happened to be a late-comer on the biological scene, contemporary research would be hard put to discover that fact. Lindegren's analogy is not very apt, for towns do not acquire public utilities by inheritance. Nevertheless, it is fair to ask why biologists should believe in something not visible in the historical record. The answer, to which molecular genetics has contributed something, can be given as follows.

If we assume kinship of living things, we at once imagine an evolutionary family tree stemming from an aboriginal branch point that represents an event of singular importance. That event, the invention of hereditary differences between lines destined to persist, I take to be conceptually equivalent to the origin of life. If we find DNA in both aboriginal branches, we conclude either that DNA function antedates the origin of life or that DNA was independently created two or more times. In fact, biochemists find a common genetic code exploited in all members of a reasonable sample of biological species. To most people, the hypothesis of unique origin provides the only economical explanation. (My weak statement reflects a certain lack of rigour in the argument. Strictly speaking, every homological explanation has an analogical equivalent.)

The same issues are raised in extreme form when experimental evolutionists suggest that life is being continually recreated. There are really two issues. On the one hand, the unity of biology speaks for unique origin. On the other hand, the complexity of the simplest forms of life suggests an inordinately low frequency of spontaneous generation: only once on Earth as far as we know and perhaps not at all in an unexplored universe. I am aware that these arguments are logically ambiguous. I am also aware that they were advanced before the phrase "molecular genetics" was coined. But I wish to make two less obvious points. First, in spite of the simplicity of the overall plan of inheritance, recent advances in molecular genetics serve only to augment, not diminish, our appreciation of biological complexity. For example, Peter Lengyel recently added up 130 known macromolecular components necessary just for the synthesis of protein. Second, without evidence for the unity of biochemistry, now clearly evident in the universality of the genetic code, the doctrine of the unity of biology would be insecure indeed, particularly with respect to the simpler forms of life. In short, life exists and we infer that it had a beginning. To find anything credible in either the fact or the inference is to miss the point.

Barry Commoner has devoted more thought to the search for weaknesses in molecular biology than anyone else (except, of course, molecular biologists). Recently[17] he cited the discovery by Speyer that mutations affecting Kornberg's DNA polymerase (an enzyme concerned with DNA synthesis) can influence the rate of further mutation. This fact shows, according to Commoner, that heritable characteristics are determined in part by nucleotide sequences in DNA, in part by the enzymes that reproduce those sequences. He has also remarked somewhere, presumably to defend his inference against obvious forms of attack, that it has not been shown that information theory is applicable to biological problems. Both these statements strike me as irresponsible: they are not untrue, just obtuse and misleading. Because Commoner is an eloquent writer[18], and has used such phrases as "theoretical crisis", "illusory successes of molecular biology", and "collision course" to manufacture conflict between "two kinds of biology", it seems worthwhile to try to straighten out the technical basis of his argument. Fleischman[19] has made one attempt. My own is a little simpler.

Long before 1953 it was evident that general mutation rates are themselves determined by genes. Geneticists described the situation as follows. The characteristics of organisms are determined by genes received from their parents and transmitted to their progeny, genes that must, therefore, be duplicated in each cell generation. But genes are not perfectly stable, or are not duplicated with perfect fidelity, whence arise the mutations that serve evolutionary purposes. Thus it is necessary to distinguish between a mechanism of duplication on which inheritance depends, and occasional mistakes made by that mechanism, few of which can be put to use. The frequency of error depends on all sorts of things—external radiation, exposure to various chemicals, temperature, ionic milieu, as well as genetic constitution itself—including, we now know, the gene-determined structure of at least one enzyme. Thus information theory, insofar as it is needed in this connexion, is just the common sense of geneticists, who saw fit to distinguish between speech and noise. I am forced to conclude that Commoner is quarrelling with the principles of genetics, and that he has not said anything about molecular biology.

Reply to the Critics

To separate my counter-criticism from the arbitrary meanings of words, I repeat it in a form that avoids loaded phrases. I have noted that agencies external to the cell, such as sources of radiation, affect mutation rates. According to Commoner's reasoning we ought, on that account, to abandon the notion that living cells can reproduce themselves.

There are, I think, more interesting limitations to current biological principles than anything pointed out by the carpers. The discovery by early geneticists that a unique set of genes determines the characteristics of the individual at once raised the question whether or not biological traits are determined exclusively by those genes. This question has never been answered and is difficult to phrase intelligibly. The demonstration by molecular biologists that a linear genetic message can be translated into three dimensional structure, as in the multiplication of virus particles, showed that in principle the known mechanisms of inheritance could be the only mechanisms. (The example of the viruses is important because there one can observe the regeneration of quite different viral species in the same cellular milieu, depending only on the kind of DNA molecule introduced at the start.) The inference that all three dimensional structure is encoded in nucleotide sequences does not necessarily follow, however. I shall call that inference the unwritten dogma, for it must be shared at least by those biologists who consider molecular biology all but finished. I turn now to some problems of cellular organization that seem to lie beyond the reach of current molecular principles. Here, if anywhere, one might expect to enter the province of biological theory.

The cell theory, dating from 1839 or earlier, engenders lengthy discussions in textbooks, discussions that are interesting but do not, I think, succeed very well in stating a theory. The central notions are: that living things come in cellular form, that cells arise only from pre-existing cells, and that all cells are homologous. Without the last proviso, the cell theory is only a historical remnant of controversy about facts. The last proviso itself comes from Darwin, not cell theorists. Discussion of the theory commonly ends with the statement that the cell is "the structural unit of life", or even "life's minimum unit"[20]. Such statements serve chiefly as a reminder that scientific theories cannot be profitably discussed outside their proper experimental context.

According to Tartar[21], the pertinent experiments are nearly as venerable as the cell theory. For example, Gruber (1885), pursuing earlier work, showed that a single cell of the protozoan genus *Stentor* could be cut into three parts, from each of which a complete animal would regenerate. In subsequent experiments with other ciliates, pieces as small as 1/80 of the cell volume were found capable of regeneration. Such experiments show that the cell is a homoeostatic unit of life, not a minimum unit, and raise the question, what is the minimum unit ? By suppressing this question, the cell theory in effect keeps living things out of the laboratory.

More useful theories divide the cell into conceptually distinct parts in the attempt to identify partial functions. Here the successes, notably enzymology and genetics, should not be allowed to overshadow the failures, such as analysis of cellular development, which also has a long history. Tartar ascribes to Prowazek (1904, 1913) what I take to be the traditional view: "Guidance of the elaboration of formed parts in the cytoplasm is to be sought in neither a nucleus of unprescribed location nor a flowing endoplasm but in the most solid portion of the cell, namely, the ectoplasm"[21]. This simplifying hypothesis divides the cell into two parts: on the one side, genes and gene products; on the other side, a cell cortex or skeleton that seems to manifest supramolecular properties. Strictly speaking, the hypothesis says nothing about the origin of the guidance system, which could in principle be recreated every time an egg is fertilized, and whenever a protozoon emerges from its cyst. But some sort of primary guiding principle is usually assumed. For example, Luria[22] remarked, in effect, that just as biological evolution is separate from cultural evolution, so is DNA evolution separate from the evolution of cellular organization. This I suspect is as close as it is possible to come to a contemporary statement of the cell theory. Like all good theories, it admits alternatives: for example, the unwritten dogma, according to which biological evolution is solely the evolution of nucleotide sequences. These alternatives were presented in essentially the same terms by Sonneborn[23].

The hypothesis of bipartite inheritance arose naturally, I think, from the fact that cellular differentiation can be reversible or not to any degree. The reversible changes seemed to imply extragenic determination and the irreversible changes suggested extragenic inheritance, that is, differentiations dating from the origins of the species. The force of this argument is now weakened by the evidence that developmental changes sometimes can be explained in terms of selective control of gene action[24]. But not all persistent changes in cell structure and behaviour can be so explained[24,25]. Before turning to the experiments, I call attention to the purely logical difficulty of imagining an experimental result requiring the hypothesis of bipartite cellular inheritance.

Acquired Traits Retained

There can be no question about evidence that certain acquired traits can persist in a cell lineage. This is not new but improved evidence, which should not be allowed to confuse us. To say that some acquired traits are inherited may be literal truth, but it sacrifices the purity of language that comes to us from Mendel: all traits are acquired, no trait is inherited, not even DNA structure is inherited, only hereditary principles are inherited, for example, nucleotide sequences. All this was explained by Johannsen[1], questioned by Wilson[3], and justified when it was found how genes really work. Only then could one invoke information theory to distinguish between what is inherited and what is merely indispensable. The possibility that cells utilize extragenic sources of information should, of course, be kept open, but it must be admitted that no one has found two biological species with identical genomes, nor has anybody proposed a plausible model for extragenic inheritance. (The notion of the primer[26], that is, a structure that is both substrate and product of enzyme action, is promising but rudimentary.)

If cells draw on an extragenic source of information, a second abstraction must be invoked, another vital principle superimposed on the genotype. A likely candidate already exists in what is usually called cell polarity, which tradition places in a rigid ectoplasm for good reason —it is a spatial principle, and as such requires mystical language. Seemingly independent of the visible structures that respond to it, polarity pervades the cell much as a magnetic field pervades space without help from the iron filings that bring it to light. Biological fields are species specific, as seen in the various patterns and symmetries of growing things[27]. The existence of polar fields is best seen in experiments with *Stentor*, whose ectoplasm contains figurative iron filings in the form of pigmented granules. The following description is condensed from Tartar's book[21].

Stentor coeruleus is an aquatic one-celled animal bearing feeding organs at its head end and a hold-fast at its tail end. The entire surface is marked by longitudinal stripes of two kinds: clear stripes carrying cilia, alternating with granular stripes without cilia. During the life of the animal, its cortical stripes grow both in width and in number. The splitting of old (wide) stripes into young (narrow) ones occurs on the ventral surface and proceeds asymmetrically, producing a circumferential (left–right) gradient of stripe widths meeting as a visible boundary on the median ventral surface.

Before each cell division, and during regeneration of decapitated animals, new mouth parts start to form in the region of stripe multiplication on the ventral surface. (The parts afterwards migrate to their proper position.) These observations define an oral primordium site lying near the junction between wide and narrow stripes. However, this site does not contain an indispensable structure, because the dorsal half of a longitudinally bisected animal regenerates a new primordium that appears in the newly created junction between wide and narrow stripes. Apparently the oral primordium develops when required at the poles of a left–right gradient, and near the equator of a longitudinal gradient.

Likewise the hold-fast comes not from a specific hereditary primordium but from something generated at the posterior pole of a longitudinal gradient. Thus if the hold-fast is tucked forward by surgical means, a second one develops at the newly created posterior pole. Animals with two mouths and one tail, or with two tails and one mouth, once created by surgical interference, reproduce as biotypes with varying degrees of stability.

A piece of cortex grafted in reverse orientation into an animal may rotate to restore normal polarities, may degenerate and disappear, or may develop its own mosaic stripe pattern. Similarly, an animal bisected transversely, and reconstructed with the head portion rotated 180° with respect to the tail, may regain its normal stripe pattern either by rotatory slippage of the two halves with respect to each other or by replacement of stripes in one of the halves through outgrowth from the other.

These experiments, like comparable experiments with *Paramecium*[24], show that polarity resides in all parts of the cell cortex. Perhaps, as many people think, polarity represents something that was invented only once and has evolved since on its own.

The well known experiments of Hämmerling on *Acetabularia*[27] set limits to the hypothesis of bipartite inheritance. In this unicellular alga the single nucleus lies at the base of an erect stalk, well separated from the growing tip. At the tip of the stalk a cap eventually forms as part of an elaborate reproductive process. The structure of the cap is species specific, and interspecies grafts show that cap structure is determined by materials originating in the nucleus or rhizoids and migrating up the stalk, to the exclusion of outgrowths from the tip. Cortical inheritance, if it exists in *Acetabularia*, is apparently not species specific. Perhaps, contrary to what many people think, polarity resides exclusively in the gene-determined structures of polar molecules, and only genes evolve. If so, the only cell theory worthy of the name is wrong.

In *Stentor* and certain other cells, all reasonably large pieces of the cell cortex are equipotent with respect to regeneration of cortical patterns—patterns that are, moreover, subject to metastable variations. In bacteriophages, supramolecular patterns do not persist as such but recur, apparently residing exclusively in the gene-determined structures of individual molecules. *Acetabularia* presents a tantalizing example somewhere in between. Taken together, the facts encourage us to see in cortical polarity a historical invention that ought to be analysable in terms of structure and process. They do not encourage us to think that the task of molecular biology is finished, even at the cellular level. In Tartar's words[21], "Our greatest lack and most fruitful opportunity in biology lies in conceiving and testing the nature and capabilities of persistent supramolecular patterns".

Marijuana Intoxication: Common Experiences

by
CHARLES T. TART
Department of Psychology,
University of California,
Davis, California 95616

As a guide to future experiments, the chief experiential effects of marijuana have been elucidated with the help of a detailed questionnaire given to seasoned marijuana users whose experiences, it seems, are almost entirely pleasant.

THE widespread use of marijuana, chiefly among college students, has raised important ethical, social and scientific questions and has stimulated some research. There is a risk, however, that studies will be unrepresentative of the effects of marijuana as it is actually used. One pitfall is the attempt to study "pure" effects in which extraneous sources of variation are minimized. Thus the report on one otherwise excellent laboratory study[1] says the "... greatest effort was made to create a neutral setting . . . verbal interactions between staff and subjects were minimum and formal . . .".

An adequate understanding of marijuana intoxication which focuses on particular effects experienced by a particular person must take into account (1) long term characteristics of the user—his personal and physiological idiosyncrasies; (2) immediate expectations and desires about what will happen during intoxication; (3) past experiences with marijuana and other psychoactive drugs as well as learned skills for modifying the drug experience; (4) immediate emotional state; (5) the social and physical setting; (6) the amount of marijuana used; and (7) chemical variations of the marijuana used. (Many of the marijuana users I interviewed insisted that certain samples of marijuana were qualitatively different from one another, and brought about different effects—laughter or sedation, for example.) During intoxication, these variables may alter as, for example, a user's companions direct his attention to new effects. Knowledge of how these variables affect marijuana intoxication is meagre, and is based almost exclusively on anecdotal accounts[2-5].

Some of the effects of marijuana may be evident only when the variables mentioned above have certain values. Other effects, which may be called "pure drug effects", may be caused exclusively by the pharmacological action of the drug. Both types are equally "real" and interesting. The traditional "neutral" setting of the laboratory, however, can provide a very limited configuration of determining variables: thus many potential effects will not show up in the laboratory situation, so that the picture of marijuana intoxication obtained there may be only partial. Indeed, it has been argued that the laboratory setting positively inhibits many important human manifestations[6-9].

These disadvantages can be overcome, however, if the investigator knows the entire normal range of effects of marijuana. My purpose here is to record this range for the benefit of future investigations. I designed a questionnaire on the basis of what I had read and learned from informal interviews with marijuana users. The questionnaire was answered by experienced marijuana users with respect to all their experiences over the preceding six months. The variables I have referred to would have been operative throughout their ranges, giving an adequate sample of the potential effects as well as the pure drug effects.

Informal interviews, chiefly with students, were carried out for two years to find out what marijuana intoxication was like. The results were combined with other descriptions of effects (see ref. 10) to give 206 descriptions of possible effects. The descriptions made up the chief part of a large questionnaire. The respondent was asked to say how often he had experienced each possible effect during the preceding six months. (The restriction to the last six months of use was intended to reduce lapses of memory. Respondents were also asked to estimate the smallest degree of intoxication necessary to experience each effect on a five-point scale: these data and more detailed analyses will be presented elsewhere.) If the description made no sense to him, he could skip it; otherwise he was asked to estimate frequency in one of five categories: (1) never; (2) rarely; (3) sometimes (between 10 and 40 per cent of time); (4) very often (more than 40 per cent of time); and (5) usually (almost always). The rest of the questionnaire consisted of questions on background (age, sex, education and experience with other psychoactive drugs).

The questionnaires were distributed by students, who were asked to pass the questionnaires on until they reached experienced marijuana users; this method was intended to ensure anonymity. A stamped return envelope was attached to each questionnaire and, of about 750 questionnaires, 153 were returned.

A letter that went out with the questionnaire was written colloquially and used the drug culture terminology. It explained the purpose of the study, asked the respondents to be as accurate as possible, and offered to make results available to anyone who wanted them after a year. It asked that only people who had used marijuana at least a dozen times should fill in the questionnaire, to avoid problems of adaptation.

Methodological Doubts

Are the answers valid ? For example, can the respondents adequately assess their experiences ? Allowing for the difficulty of putting precise words to inner experiences, it seemed from the informal interviews that educated marijuana smokers could give fairly articulate descriptions; and the respondents in this study were highly educated. Comprehensive interviews to determine a more adequate vocabulary are needed, but most of the possible effect descriptions seemed understandable and conveyed what the users wished to express. To check carelessness or deliberately bizarre answers, I added fourteen extra descriptions of possible effects randomly among the original 206. They constituted a validity scale by referring to unheard-of effects. Any questionnaire with six or more positive responses to them was to be rejected without further analysis; three were in fact rejected, leaving 150 that could be used.

A further objection: might the respondent overstress positive effects in order to justify his drug use? One cannot be certain, but two steps were taken to reduce the possibility. First, the accompanying letter was designed to appear sympathetic to marijuana use, so there was no need to win over the investigator. Second, the letter appealed to the respondents' curiosity about other users' experiences and to their loyalty to other users: because it promised to make the results available, the respondents would benefit by being accurate. Negative, unpleasant effects, are, nevertheless, under-represented in the replies, and interpretations should take account of the lack. By definition, an "experienced" marijuana user is an enthusiast; it would be somewhat perverse to indulge continually in criminal behaviour that is personally unpleasant.

Because my purpose is to ascertain the common effects of marijuana intoxication rather than the effects in specific populations, I describe here only major characteristics of the sample. The respondents were chiefly young Californians (67 per cent), with some East Coast respondents (11 per cent); 87 per cent were under 30 years old. There were twice as many males as females. 67 per cent were students, and 71 per cent unmarried. Only 7 per cent had had no college training, and 21 per cent had pursued graduate work or had earned advanced degrees. Only 4 per cent had been arrested for possessing marijuana. Many of the respondents were interested in self-improvement: 36 per cent reported that they practise some sort of discipline for spiritual or personal growth. 74 per cent of the sample had smoked marijuana for between six months and three years; the average frequency of use during the preceding six months ranged from "almost every day" (19 per cent) to "once a week or more" (42 per cent) to less than once a week (39 per cent). 72 per cent had tried more powerful psychoactive drugs such as LSD-25 at least once, 47 per cent of them in the six months covered by the questionnaire. Few (7 per cent) had used hard narcotics or dangerous stimulants (amphetamine or methedrine by injection). The respondents had used marijuana to alter their state of consciousness more than twice as frequently as alcohol in the preceding six months.

I classify the results into three categories: first, a large number of effects that may be considered common; second, a smaller number of effects that occur so frequently that they may be considered characteristic (these are shown by an asterisk in the list of "common effects"); third, some infrequent effects that seem at face value to be very significant. "Common" is here defined as being rated as "Sometimes", "Very Often", or "Usually" by at least 50 per cent of the respondents; "characteristic" as being rated "Very Often" or "Usually" by at least 50 per cent of the respondents.

The descriptions of possible effects within the "common effects" category are given in the wording of the questionnaire, except that the qualifying phrase "the effect is more pronounced during marijuana intoxication ['while stoned'] than normally" is usually omitted to save space, and some parts of the descriptions are omitted if the meaning is not thereby affected. The descriptions are put into sixteen classes, although some are relevant to more than one class. Within each class, the descriptions begin with the most common; the figures given are the total percentages of respondents putting an effect into the "Sometimes", "Very Often", or "Usually" categories.

Common Effects

Visual effects: (1) I can see patterns, form, figures, meaningful designs in visual material that does not have any particular form when I'm straight, that is just a meaningless series of lines or shapes when I'm straight, 85*. (2) If I try to visualize something . . . I see it in my mind's eye more sharply. . . , 81*. (3) When looking at pictures they may acquire an element of visual depth, a third dimensional aspect. . . , 72. (4) Things seen are seen more sharply in that their edges, contours stand out more sharply against the background, 72. (5) I can see new colours or more subtle shades of colour . . . , 70. (6) There is a sensual quality to vision, as if I were somehow "touching" the objects or people I am looking at, 59. (7) . . . things in the periphery of my vision look different when I'm not looking directly at them . . . , 58. (8) My visual perception of the space around me is changed so that what I'm looking at is very real and clear but everything else I'm not focusing on visually seems further away or otherwise less real or clear, 58.

Auditory effects: (1) I can hear more subtle changes in sounds, for example, the notes of music are purer and more distinct, the rhythm stands out more, 99*. (2) I can understand the words of songs which are not clear when straight, 85*. (3) When listening to stereo music or live music, the spatial separation between the various instruments sounds greater, as if they were physically further apart, 82*. (4) If I try to have an auditory image . . . it is more vivid . . . , 73. (5) With my eyes closed and just listening to sounds, the space around me becomes an *auditory* space, a space where things are arranged according to their sound characteristics instead of visual, geometrical characteristics, 65. (6) The sound quality of my voice changes, so that I sound different to myself when I talk, 63.

Touch effects: (1) My sense of touch is more exciting, more sensual . . . , 86*. (2) Touch sensations take on new qualities . . . , 85*. (3) Some surfaces feel much smoother, silkier, 77. (4) Some surfaces feel much rougher, irregular . . . and the roughness or graininess forms interesting patterns, 73. (5) The temperature of things . . . takes on new qualities, 69. (6) I can experience vivid tactual imagery . . . , 60. (7) Objects seem heavier, more massive when I lift them, 55.

Taste effects: (1) Taste sensations take on new qualities, 93*. (2) I enjoy eating very much and eat a lot, 93*. (3) If I try to imagine what something tastes like, I can do so very vividly, 69. (4) I crave sweet things to eat, like chocolate, more than other foods, 57.

Smell effects: (1) Smell sensations take on new qualities, 71. (2) Smells become richer and more unique . . . , 69.

Space-time perception: (1) When I walk someplace my experience of the distance covered is quite changed . . . , 96*. (2) Time passes very slowly . . . , 95*. (3) Distances between me and things or me and other people seem to get greater . . . , 69. (4) Events and thoughts flow more smoothly, the succession of events in time is smoother than usual, 69. (5) I get so lost in fantasy or similar trips in my head that I completely forget where I am, and it takes a while to reorient after I come back and open my eyes, 63. (6) Time seems to stop: it's not just that things take longer, certain experiences seem outside of time, are timeless, 63. (7) Events and thoughts follow each other jerkily, there are sudden changes from one thing to another, 59. (8) While something is happening I get the funny feeling that this sequence has happened before in exactly the same way . . . (*déjà vu*) . . . , 55. (9) Distances . . . seem to get shorter . . . , 53.

Perception of the body: (1) I feel a lot of pleasant warmth inside my body, 71. (2) If I am paying attention to some particular part of my body, the rest of my body fades away a lot so the part I'm attending to stands out more sharply, 69. (3) I am much more aware of the beating of my heart, 69. (4) With my eyes closed, my body may feel very light or even feel as if I float up into the air, 68. (5) I have lost all consciousness of my body during fantasy trips . . . , 66. (6) I get feelings in my body that are best described as energy, force, power of some sort flowing, 65. (7) I lose awareness of most of my body unless I specifically focus my attention there or some particularly strong stimulus demands my attention there, 61. (8) I become very aware of my breathing and can feel the breath flowing in and out of my throat as well as filling my lungs, 60. (9) Pain is easy to tolerate if I keep my attention elsewhere, 59. (10) I feel a vibration or tingling sensation in some or all of my body that I can tell is not an actual muscle tremor by looking at my body, 57. (11) Pain is more intense if I concentrate on it, 54.

Physical movement: (1) I get physically relaxed and don't want to get up or move around, 95*. (2) When I move about or dance my motions seem exceptionally smooth and well coordinated, 81*. (3) I get physically restless so that I want to move around a lot, 58. (4) I feel much weaker when stoned (regardless of whether you're actually physically stronger or weaker), 51.

Interpersonal relations: (1) I have feelings of deep insights into other people, how they tick, what their games are (regardless of whether they actually check out later), 85*. (2) I find it very hard to play ordinary social games, 83*. (3) I empathize tremendously with others, I feel what they feel, I have a tremendous intuitive understanding of what they're feeling, 83. (4) I talk a lot less, 83. (5) I am less noisy and boisterous at parties, 82*. (6) I am less noisy and boisterous at parties than when drunk or tipsy on alcohol, 82*. (7) When stoned with others I play "childish" games, that is, we interact with each other in ways which are very enjoyable but which people would ordinarily consider "childish", 80. (8) I feel the things I say in conversation are more profound and appropriate to the conversation, more interesting, 79. (9) I become more sociable, I want to be with and interact with people more, 76. (10) When stoned with a group of people, the group takes on a much greater sense of unity, or real social relationship . . . , 75. (11) I become less sociable; I want to be by myself, 73. (12) Being with people who are much higher than I am (as from their being on acid (LSD) or much more stoned on grass) gets me higher, even though I don't smoke any more grass, 70. (13) I talk a lot more, 64. (14) I feel isolated from things around me . . . , 50.

Sexual effects: (1) Sexual orgasm has new qualities, pleasurable qualities, 77*. (2) When making love I feel I'm in much closer mental contact with my partner; it's much more a union of souls as well as bodies, 76. (3) I have no increase in sexual feeling unless it's a situation that I would normally be sexually aroused in, and then the sexual feelings are much stronger and more enjoyable, 75. (4) My sexual drive goes up, I have more need for sex, 61. (5) I feel as if I'm a better person to make love with when stoned, 52.

Thought processes: (1) I appreciate very subtle humour in what my companions say, and say quite subtly funny things myself, 91*. (2) Commonplace sayings of conversations seem to have new meanings, more significance, 87. (3) I give little or no thought to the future, I am completely in the here-and-now, 87*. (4) Spontaneously, insights about myself, my personality, the games I play, come to mind when stoned and seem very meaningful, 86*. (5) The ideas that come to my mind are much more original, 83. (6) I find it difficult to read, 80*. (7) I think about things in ways that seem intuitively correct, but which do not follow the rules of logic, 78. (8) . . . I think much more in (visual) images instead of just abstract thought, 75. (9) I am more willing to accept contradictions between two ideas or two views . . . I don't get uptight because the two things don't make immediate sense, 74*. (10) If I deliberately work on it, I can have important insights about myself, my personality, the games I play, 73. (11) I learn a great deal about psychological processes . . . general knowledge about how the mind works (as opposed to specific insights about yourself), 71. (12) I get so wound up in thoughts or fantasies that I won't notice what's going on around me . . . , 69. (13) I get so wound up in thoughts or fantasies while doing some physical task or job that I lose awareness of doing it, yet suddenly find that I have finished the physical task . . . , 67. (14) I have more imagery than usual while reading; images of the scene I'm reading about just pop up vividly, 67. (15) I do things with much less thought to possible consequences of my actions . . . , 65. (16) If I try to solve a problem, it feels as if my mind is working much more efficiently than usual (regardless of how you evaluate the solution later), 64. (17) If I work on a problem, I work less accurately as judged by later real-world evaluation, 63. (18) I can play elaborate games and get very involved in the games, 60. (19) If I try to solve a problem it feels as if my mind is much less efficient . . . , 56. (20) In thinking about a problem of the sort that normally requires a series of steps to solve, I can get the answer without going through some of the usual intermediate steps . . . , 53.

Memory functioning: (1) My memory span for conversations is somewhat shortened, so that I may forget what the conversation is about even before it has ended (even though I may be able to recall it if I make a special effort), 89*. (2) I can continue to carry on an intelligent conversation even when my memory span is so short that I forget the beginnings of what I started to say; for example, I may logically complete a sentence even as I realize I've forgotten how it started, 72. (3) I can't think clearly, thoughts keep slipping away before I can quite grasp them, 71. (4) My memory span for conversations is very shortened so that I may forget what the start of a sentence was about even before the sentence is finished . . . , 68. (5) I spontaneously remember things I hadn't thought of in years . . . , 61. (6) If I read while stoned, I remember less of what I've read hours later, 61. (7) I think I've said something when actually I've only thought about saying it . . . , 57. (8) My memory of what went on while I was stoned is poor afterwards . . . , 57. (9) My memory of what went on is . . . better than if I had been straight, 55.

Emotions: (1) I feel emotions much more strongly, so they affect me more, 80. (2) I almost invariably feel good when I turn on, regardless of whether I felt bad before turning on, 80*. (3) I am more aware of the body tensions and feelings that are part of emotions, 74. (4) Whatever mood I was in before turning on becomes greatly amplified; so if I felt let down I really feel bad, and if I felt good, I really feel very good, 72.

Self-control: (1) I find it easy to accept whatever happens, I don't need to control it or feel in control of it, 89*. (2) I can "come down" at will if I need to be straight for a minute to deal with some complicated reality problem, 89*. (3) I often forget to finish some task I've started, or get sidetracked more frequently than when straight, 86*. (4) I giggle a lot when stoned, I am silly, even though the situation is not that funny, 74. (5) I have excellent control over my fantasies; I can make them go in whatever direction I want, 73. (6) My inhibitions are lowered so that I do things I'm normally too inhibited to do (Note: this does not apply to antisocial acts but to acts that are generally acceptable but that you normally can't do through shyness or the like), 69. (The immediately following item was, "I lose control of my actions and do antisocial things [actions that harm other people] that I wouldn't normally do." The response was 77 per cent never, 22 per cent rarely, and one respondent sometimes.) (7) I can work at a necessary task with extra energy, absorption and efficiency, 61. (8) I feel as if I lose control over my thoughts; they just go on regardless of what I want (without reference to whether you like this or not), 52.

Sense of identity: (1) I feel very powerful, capable, and intelligent, 71. (2) Some events become archetypal, part of the basic way Man has always done things. That is, instead of me (John Doe, ego) doing something, it is just Man Doing What Man Has Always Done . . . , 57. (3) I lose all sense of self, of being a separate ego, and feel at one with the world, 55.

Effects on sleep: (1) I find it very easy to go to sleep at my usual bedtime when stoned, 84*. (2) I get very drowsy even though it's not late . . . , 83. (3) My sleep is particularly refreshing if I go to bed stoned, 81. (4) My dreams are more vivid if I go to bed stoned, 51.

Miscellaneous effects: (1) I feel more childlike, more open to experiences of all kinds, more filled with wonder and awe at the nature of things, 91*. (2) I get more involved in ordinary tasks, 80. (3) Others (who were straight at the time) have not noticed that I've been stoned (applied to other people who were your friends and would have told you if they'd noticed), 69. (4) With my eyes closed my inner visions and fantasies become extremely real, as real as night-time dreams, 68. (5) Some of my inner trips, eyes-closed fantasies, have been so vivid and real that even though I know logically they couldn't be real, they feel real; they are as real as ordinary waking life experience, 57. (6) Sounds have visual images or colours associated with them, synchronized with them, 55.

Infrequent but Significant Effects

The following effects were not reported often enough to be classed as common, but they seem so powerful and unusual that they might well change somebody's beliefs. The numbers given are the percentages of respondents who have experienced the effect at all.

(1) I feel so aware of what people are thinking that it must be telepathy, mind reading, rather than just being more sensitive to the subtle cues in their behaviour, 69; (2) Getting stoned has acquired a religious significance for me, 69; (3) I have spiritual experiences . . . which have had a powerful, long-term religious effect on me, 65; (4) I feel in touch with a Higher Power or a Divine Being to some extent . . . , I feel more in contact with the "spiritual" side of things, 59; (5) I am able to meditate more effectively, 39; (6) I can foretell the future by some kind of precognition, more than just logically predicting from present events, 32; (7) . . . felt "located" outside the physical body . . . , 32; (8) I can perform magical operations that will affect objects or people, 13.

The way in which items were selected for the questionnaire (informal interviewing) produced a set of items that were almost uniformly positive or neutral in tone; there were almost no "bad" effects. But a few negative effects included in the questionnaire are powerful enough to seem important, even if they are infrequent. Figures are again the percentages of respondents who have experienced the effect at all.

(9) I get somewhat paranoid about the people with me, I am suspicious about what they're doing, 80; (10) I lose control of my actions and do antisocial things (things that harm other people), 23; (11) I have lost control and been "taken over" by an outside force or will which is hostile or evil in intent for a while, 20.

One question asked the respondents how often they had seen other people "freak out", that is, have intense, transient emotional upsets. 62 per cent of the respondents said never, 36 per cent less than one time in twenty, and 2 per cent more often. Fifty-three respondents answered a question about what sort of help was necessary for the person who "freaked out"; usually (64 per cent) friends talked to the person and calmed him. Medical or psychological aid was used in 13 per cent of cases, with other methods or no special help for the rest. When the respondents were asked how many times they had "freaked out" themselves, 79 per cent answered never, 14 per cent once, and 7 per cent more than once. The respondents themselves were usually calmed down by friends (56 per cent) or had the "freakout" subside by itself or through their own efforts (37 per cent).

These figures probably represent a higher incidence of "freakouts" on marijuana than actually occurs: because of the method of distributing questionnaires, many of the respondents may have been reporting on the same cases of emotional difficulties in others.

Pleasures of Being High

124 of the 206 items on the questionnaire may thus be considered common experiential effects of marijuana intoxication. Sense perception is often improved, both in intensity and in scope. Imagery is usually stronger but well controlled, although people often care less about controlling their actions. Great changes in perception of space and time are common, as are changes in psychological processes such as understanding, memory, emotion, and sense of identity.

This is not the place to theorize about the results, but they are quite consistent with an earlier, independent description: " . . . Sensations are enhanced and clarified: sight, hearing, taste, touch. Time perception changes. Attention becomes more unified, and moves more into preconscious material and the state of pure awareness. The many broad processes of association, such as social meanings, memory images, expectancies and plans, are reduced in number and relevance. Inhibitions and suppressions relax, allowing emotions, thoughts, fantasies, and memories to flow more freely. The development and strength of these effects will depend on the individual, the times he has used marijuana, how he has used marijuana, and the environment"[11]. Although the validity of the descriptions cannot be proved, there is at least a great deal of agreement among the respondents. To the extent that the described effects are delusory or inaccurate, the delusions and inaccuracy are widely shared. It is interesting, too, that nearly all the common effects seem either emotionally pleasing or cognitively interesting, and it is easy to see why marijuana users find the effects desirable regardless of what happens to their external behaviour. But it should be remembered that negative effects are probably somewhat under-represented.

This research was supported in part by the US Public Health Service. I thank Mrs Joan Crawford for her help in data processing and, of course, the respondents, who spent several hours filling in the questionnaires.

Specificity in Bacterial Protein Synthesis: Role of Initiation Factors and Ribosomal Subunits

by
HARVEY F. LODISH
Department of Biology,
Massachusetts Institute of Technology,
Cambridge, Massachusetts, 02139

Ribosomes from *E. coli* initiate synthesis *in vitro* of all three of the proteins coded by phage f2, but ribosomes from *B. stearothermophilus* initiate synthesis of only one. The specificity of initiation depends only on the source of the 30S subunits; the origin of the 50S subunits and initiation factors has no effect.

THE initiation of protein synthesis in bacteria involves two ribosome subunits, messenger RNA containing an AUG or GUG initiator codon, GTP, N-formylmethionyl-tRNA, and at least three protein initiation factors[1-7]. Most AUG or GUG sequences on a messenger, however, do not normally act as signals for polypeptide chain initiation; rather they code for an internal amino-acid or they are out of phase with the normal reading frame. The complex of ribosomes and initiation factors (which normally are isolated together) plays a critical part in recognizing the proper AUG (or GUG) sequences on a messenger as signals for initiation[8,9]. Addition of RNA from bacteriophage f2 to a cell-free system containing the ribosome–factor complex from its host cell, *Escherichia coli*, results in synthesis of all three f2 proteins: coat protein, RNA replicase and maturation protein[8,10-13]. By contrast, ribosomes from *Bacillus stearothermophilus* direct synthesis only of the maturation protein, the product made in least amounts by *E. coli* ribosomes. The origin of transfer RNA or supernatant enzymes had no effect on the product formed[8,9]. Direct experiments have confirmed that *B. stearothermophilus* ribosomes bind only to the sequence on f2 RNA which codes for the amino terminus of the maturation protein[13].

Initiation factors are required for translation only of messenger RNAs which contain an AUG or GUG initiator codon[1,3-5]. One factor (B or f3) is required for binding ribosomes to natural messenger RNA, but not to certain synthetic messenger RNAs which contain an AUG initiation sequence[5,14,15]. This suggests that the initiation factors serve to recognize the proper initiation sequences on a natural messenger RNA. We show here, however, by experiments which mix components of the *E. coli* and *B. stearothermophilus* systems, that it is the origin of the 30S ribosome subunits which determines which f2 proteins are produced; the species from which the initiation factors or 50S subunits are isolated is irrelevant. Thus the 30S subunit selects regions of messengers as signals for the initiation of polypeptide synthesis; the three initiation factors and the 50S subunit, while essential for translation of natural messenger RNA, appear to have no function in this process.

Lack of Specificity of Initiation Factors

Ribosomes and initiation factors were prepared from both *E. coli* and *B. stearothermophilus* extracts by ultracentrifugation in 2 M NH_4Cl solutions (see legend to Table 1). In the absence of initiation factors, both types of ribosomes are completely inactive in directing protein synthesis with either f2 RNA (Fig. 1, Table 1), *E. coli* mRNA, or T4 mRNA (unpublished). By contrast, with poly U as messenger, both ribosomes had the same high activity in directing synthesis of polyphenylalanine, and addition of either preparation of initiation factors had no effect (less than ±20 per cent) (unpublished). Using f2 RNA, ribosomes from either species were stimulated by either factor preparation. Regardless of the factor used, *E. coli* ribosomes synthesized 15–20 times as much f2 protein as did *B. stearothermophilus* ribosomes.

To determine which f2 proteins were synthesized by the different ribosome-factor mixtures, we identified their N-termini by their content of N-formylmethionine. f2 specific proteins synthesized *in vitro* and labelled with ^{35}S fMet-tRNA were digested with trypsin and chymotrypsin and subjected to paper chromatography and ionophoresis at *p*H 3·5 as described previously[8-10,16]. Table 1 shows that addition to *B. stearothermophilus* ribosomes of either *B. stearothermophilus* or *E. coli* initiation factors results in synthesis of only the f2 maturation protein. Conversely, addition of either preparation of factors to *E. coli* ribosomes results in normal synthesis of all three f2 proteins. A control experiment (last line, Table 1) shows that *B. stearothermophilus* ribosomes contain nothing which might destroy either the capacity of f2 RNA to synthesize coat protein or any coat or RNA replicase produced[8].

These results mean that the nature of proteins synthesized is determined solely by the nature of the ribosomes; the initiation factor preparations do not, in this system at least, contribute to the specificity of protein synthesis. In particular, *B. stearothermophilus* initiation factors allow *E. coli* ribosomes to synthesize both the f2 coat and RNA replicase proteins even though the mixture

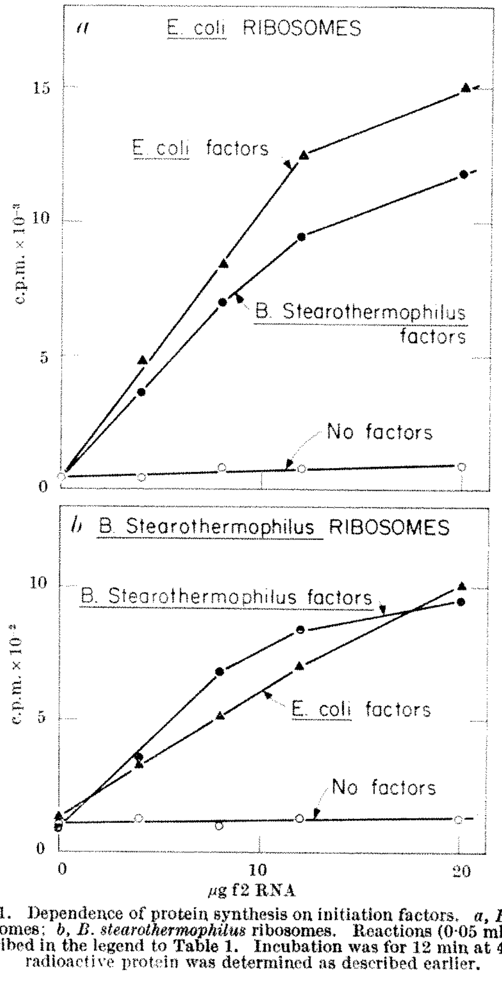

Fig. 1. Dependence of protein synthesis on initiation factors. *a*, *E. coli* ribosomes; *b*, *B. stearothermophilus* ribosomes. Reactions (0·05 ml.) are described in the legend to Table 1. Incubation was for 12 min at 47° C; radioactive protein was determined as described earlier.

Table 1. EFFECT OF INITIATION FACTORS ON PROTEIN SYNTHESIS BY f2 RNA

Ribosomes	Factors	RNA	c.p.m. reaction Coat	Poly-merase	Matura-tion
E. coli	0	0	(56)	(65)	(51)
		f2	420	200	17
	E. coli	0	(61)	(38)	(66)
		f2	46,864	24,648	1,989
	B. stearothermophilus	0	(63)	(54)	(39)
		f2	35,526	21,435	1,632
B. stearothermophilus	0	0	(41)	(31)	(49)
		f2	43	15	−6
	E. coli	0	(89)	(74)	(41)
		f2	14	26	3,480
	B. stearothermophilus	0	(115)	(81)	(77)
		f2	−7	51	4,320
E. coli plus *B. stearothermophilus*	*E. coli*	0	(79)	(133)	(120)
		f2	44,920	27,100	2,940

Reactions (0·30 ml.) contained, per ml.: 50 μmoles ammonium cacodylate (pH 7·0), 100 μmoles NH_4Cl, 9 μmoles magnesium acetate, 10 μmoles 2-mercaptoethanol, 2 μmoles ATP, 4·2 μmoles PEP, 0·3 μmoles GTP, 0·1 μmoles each of twenty non-radioactive amino-acids; 500 μg *E. coli* tRNA charged only with ^{35}S-N-formylmethionine[16] (5,500 mCi/mmole), 0·20 ml. S100 from *B. stearothermophilus*; and, where indicated, 200 μg f2 RNA; 40 $A_{260\ nm}$ units *E. coli* ribosomes, 56 $A_{260\ nm}$ units *B. stearothermophilus* ribosomes; 280 μg crude *E. coli* initiation factors; and 360 μg crude *B. stearothermophilus* initiation factors. Incubation was at 47° C for 12 min. Isolation of the radioactive protein, digestion with trypsin and chymotrypsin, and separation and quantitation of the amino terminal peptides of the phage proteins have been described previously[8,16,25]. Backgrounds from samples without f2 RNA have been subtracted from the f2 samples. Ribosomes and initiation factors were prepared by a modification of the technique of Anderson *et al.*[1]. Frozen *E. coli* PR7 or *B. stearothermophilus* strain 10 log-phase cells[18] were ground with 2·5 weights of alumina, extracted with 3 volumes of 0·03 M Tris (pH 7·8), 0·06 M KCl, 0·01 M magnesium acetate, 0·003 M 2-mercaptoethanol (buffer A) containing 1 μg/ml. deoxyribonuclease and centrifuged twice for 20 min at 20,000g. To the supernatant ATP and PEP (final concentrations 0·0025 M and 0·0035 M, respectively) were added, and the mixture was preincubated 1 h at 30° C (*E. coli*) or 55° C (*B. stearothermophilus*). Careful control experiments showed the preincubation resulted in no loss of the ability to support f2 or T4 RNA directed protein synthesis. The extract was centrifuged 4·5 h at 40,000 r.p.m. in the Spinco '40' or '65' rotor; the ribosomal pellet was resuspended in buffer A, clarified by low speed centrifugation and pelleted again in the ultracentrifuge. The pellet was resuspended overnight in 2·0 M NH_4Cl, 0·05 M Tris (pH 7·8), 0·01 M magnesium acetate, 0·006 M mercaptoethanol (buffer B) and then the ribosomes were sedimented in the ultracentrifuge for 5 to 6 h at 45,000 r.p.m. Initiation factors were prepared from the top half of the supernatant by $(NH_4)_2SO_4$ precipitation[1]. The ribosomal pellet was resuspended again overnight in buffer B, recentrifuged, resuspended in buffer A, and stored frozen in small aliquots at −80° C.

of *B. stearothermophilus* ribosomes and factors synthesizes neither.

If supernatant enzymes are omitted, this system can form only the first peptide bond of the f2 proteins. After alkaline hydrolysis of the resultant dipeptidyl-tRNA linkage, the ^{35}S peptides can be analysed by paper ionophoresis at pH 3·5. Without added viral RNA (Fig. 2*b*, *d*), the only products are radioactive methionine, formylmethionine, and formylmethionine sulphoxide, all of which are derived from the tRNA added to the reaction[17]. Addition of f2 RNA to *E. coli* ribosomes and factors results in formation of two new radioactive peptides, I and II (Fig. 2*c*). Peptide I is N-formylmethionylalanine, the dipeptide at the amino terminus of the coat protein[17]. Peptide II is N-formylmethionylarginine, the dipeptide found at the amino terminus of the maturation protein[8,9]. These results show that *E. coli* ribosomes direct synthesis of the first peptide bond of both the f2 coat and maturation proteins[17]. No N-formylmethionylserine, the amino terminal peptide of the RNA replicase, is seen[16], suggesting that ribosomes normally cannot directly initiate synthesis of this protein[16–18].

By contrast, *B. stearothermophilus* ribosomes and initiation factors only direct synthesis of peptide II, from the maturation protein, and no peptide I from the coat (Fig. 2*a*, Table 2). Control experiments (Table 2), in which *E. coli* and *B. stearothermophilus* ribosomes were mixed, showed that the latter contain no inhibitor for the synthesis of fMet-Ala. Table 2 shows that formation of any formylmethionyl dipeptide by ribosomes from either species is dependent on addition of initiation factors. Addition of either *E. coli* or *B. stearothermophilus* factors to *E. coli* ribosomes permits normal formation of the first peptide bond of both coat and maturation protein. Also, addition of either factor preparation to *B. stearothermophilus* ribosomes permits initiation only of the maturation protein. Again, the nature of the proteins initiated is determined only by the origin of the ribosomes, and not of the initiation factors.

Role of Ribosome Subunits

Table 3 shows that addition of purified *E. coli* 30S subunits to an f2 RNA primed *B. stearothermophilus* cell-free system causes the synthesis of high levels of both f2 coat protein and RNA replicase protein (in addition to the normal synthesis of maturation protein). Addition of an equivalent amount of unfractionated *E. coli* ribosomes (30S + 50S) has the same effect, while addition of purified *E. coli* 50S subunits induces little synthesis of either coat or replicase. The small synthesis of these proteins can be accounted for by the 7 per cent contamination of the 50S subunit preparation by 30S subunits (see Table 3). This experiment shows that the *E. coli* 30S subunit, and not the 50S subunit, is responsible for recognition of the regions of f2 RNA which code for initiation of coat and replicase synthesis.

Thus the nature of proteins synthesized by f2 RNA is determined only by the origin of the 30S ribosomal subunit; 30S ribosome subunits from *E. coli* direct synthesis of all three f2 proteins, while *B. stearothermophilus* 30S subunits direct synthesis of only the f2 maturation protein. This effect is independent of the origin of the 50S subunits (Table 3), initiation factors (Tables 1, 2), transfer RNA, or supernatant enzymes. Ribosomes from the mesophile *B. megaterium* translate the same f2 protein as do those from *B. stearothermophilus* (unpublished results of T. Johnson and H. F. L.).

We have also studied messenger RNA from growing *E. coli* cells, and from cells 5 and 15 min after infection by T4 phage. In an *E. coli* cell-free system all three messengers induced the synthesis of 15–20 new proteins, as shown by peptide mapping of protein labelled by ^{35}S-fMet-tRNA. *B. stearothermophilus* extracts synthesized only about one-fourth of the *E. coli* mRNA directed proteins and two-thirds of the T4-specific proteins. Mixing experiments analogous to those reported here on f2 RNA showed that the nature of the proteins produced depended on the origin of the ribosome subunits, and not on the species from which initiation factors were isolated.

Table 2. SYNTHESIS OF FIRST PEPTIDE BOND OF COAT AND MATURATION PROTEIN

Ribosomes	Factors	f2 RNA	Peak I fMet-Ala (coat)	Peak II fMet-Arg (maturation)
E. coli	0	0	(116)	(114)
		f2	−21	−24
	E. coli	0	(206)	(160)
		f2	1,902	636
	B. stearothermophilus	0	(149)	(120)
		f2	1,310	440
B. stearothermophilus	0	0	(89)	(101)
		f2	−2	2
	E. coli	0	(116)	(118)
		f2	−33	717
	B. stearothermophilus	0	(139)	(149)
		f2	−41	641
E. coli plus *B. stearothermophilus*	*B. stearothermophilus*	0	(113)	(116)
		f2	914	540

Reactions (0·3 ml.) were as described in the legend to Fig. 2, except that ribosomes, washed in 2 M NH_4Cl solution, and initiation factors were used at the concentrations described in the legend to Table 1. Analysis of the reaction products is described in the legend to Fig. 2. Backgrounds from reactions without f2 RNA (in parentheses) have been subtracted from the values from the f2 reactions.

Table 3. EFFECT OF ADDITION OF *E. coli* SUBUNITS

Additions	c.p.m./reaction Coat	Polymerase	Maturation
(No RNA)	(160)	(123)	(229)
f2 RNA	116	195	4,618
f2 RNA plus 11 *A* units *E. coli* 30S + 50S	27,728	6,492	2,791
f2 RNA plus 5·1 *A* units *E. coli* 30S	18,857	4,080	2,060
f2 RNA plus 7·4 *A* units *E. coli* 50S	2,767	718	2,066

Reactions (0·5 ml.) were as described in the legend to Table 1, except 0·30 ml. of preincubated *B. stearothermophilus* S-30[16] was used in place of S100 and *B. stearothermophilus* ribosomes. *E. coli* ribosomes, washed twice in buffer A, were separated into subunits by dialysis overnight in 0·03 M Tris (pH 7·8), 0·1 M NH_4Cl, 0·0005 M magnesium acetate, 0·003 M 2-mercaptoethanol (buffer C) and centrifugation in a 15–30 per cent sucrose gradient in buffer C ('SW 27' rotor in Beckman 'L2–65B' ultracentrifuge). To the 30S and 50S peak tubes was added magnesium acetate to 0·01 M, and then three volumes of buffer A; the subunits were pelleted by ultracentrifugation, resuspended in buffer A, run through a second sucrose gradient (5–20 per cent in buffer A), then pelleted as above, and resuspended in buffer A. On analysis in small sucrose gradients (12 ml. 5 to 20 per cent gradients in buffer A, 'SW 36' rotor), the 30S subunits contained no detectable 50S, while in the 50S preparation 5 to 8 per cent of the $A_{260\ nm}$ was in 30S subunits. An aliquot of the ribosomes just before layering on the first sucrose gradient was taken, made 10^{-2} M in Mg^{2+}, and used at the "30S + 50S" preparation (line 3).

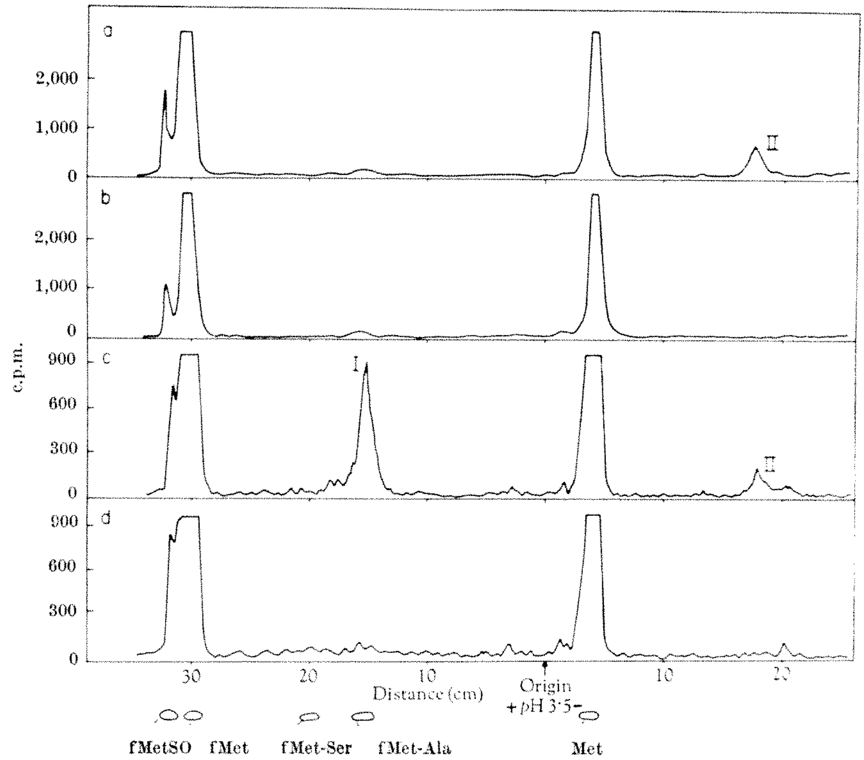

Fig. 2. Synthesis of first peptide bond of f2 proteins by *E. coli* and *B. stearothermophilus* ribosomes. *a*, *B. stearothermophilus* ribosomes plus f2 RNA; *b*, *B. stearothermophilus* ribosomes; *c*, *E. coli* ribosomes plus f2 RNA; *d*, *E. coli* ribosomes. Reactions[17] (0·1 ml.) contained, per ml., 100 µmoles HEPES (pH 7·0), 50 µmoles KCl, 8 µmoles magnesium acetate, 0·3 µmoles GTP, 500 µg *E. coli* tRNA charged with ^{35}S-methionine (5,600 mCi/mmole, about 70 per cent of methionine tRNA formylated) and nineteen non-radioactive amino-acids, 38 $A_{260\ \text{nm}}$ units of *E. coli* ribosomes or 50 $A_{260\ \text{nm}}$ units *B. stearothermophilus* ribosomes. Both ribosome preparations were washed three times in buffer A only, and retained all of the initiation factors. Incubation was for 10 min at 47° C; 0·5 ml. 0·4 M triethylamine was added and the reaction incubated at 37° C for 1 h. After lyophilization, the samples—together with marker peptides—were analysed by paper ionophoresis at pH 3·5. Radioactivity was measured in a Packard '7201' strip scanner at 0·2 cm/min, with a 1,000 c.p.m. scale[17].

B. stearothermophilus and *E. coli* factors stimulated *E. coli* ribosomes to make all of the *E. coli* and T4-specific proteins, while *E. coli* factors could not induce *B. stearothermophilus* ribosomes to synthesize the proteins not usually made. We shall report these experiments elsewhere.

The first step in the initiation of protein synthesis is the interaction of the 30S ribosome subunit, messenger RNA, and two initiation factors, B (f3) and C (f2). The initiator, fMet-tRNA, and the third factor, A (f1), are added, and finally the 50S subunit and the second aminoacyl-tRNA[1-5,19,20]. The work of Steitz[13] and Hindley[21] suggests that the site on the messenger to which the 30S subunit attaches is identical to the site at which protein synthesis is initiated. At least two considerations seem to determine which of many AUG or GUG sequences on a messenger serve as initiation signals.

First, the secondary structure of the messenger may restrict certain AUG or GUG codons from acting as initiator sequences. As shown by sequence analysis of parts of the phage RNA, many non-initiating AUG sequences seem to be in small double-stranded regions[13,21-23]. Moreover, mild disruption of f2 RNA by reaction with formaldehyde allows the RNA to initiate at least three new polypeptides which do not correspond to any known f2 protein[9,18]. This implies that in f2 RNA there are AUG sequences which can initiate protein synthesis, but are prevented by the RNA structure from doing so.

Second, our experiments show that the 30S subunit recognizes only some of the "exposed" AUG sequences as actual initiation signals. We suggest that the initiation factors, particularly factor B (f3)[3,14,24], do not play any part in messenger recognition. If factor B were to play such a part, it should comprise two or more components to enable it to recognize different initiation signals on different messengers; no such separation has been reported.

This research was supported by grants from the US National Institutes of Health and the American Cancer Society. I thank Mrs Marion Jacobsen for technical assistance.

Excision-repair Properties of an *Escherichia coli* Mutant deficient in DNA Polymerase

An *Escherichia coli* mutant, extracts of which show no DNA polymerase activity, can excise pyrimidine dimers induced by ultraviolet irradiation. The increased radiation sensitivity of this strain is related to the extensive degradation of irradiated DNA.

An excision-repair mechanism for correcting structural distortions of the Watson–Crick helical structure of DNA was proposed in 1964[1,2]. An extensively used system for investigating the proposed mechanism has been DNA that contains cyclobutane-type pyrimidine dimers produced by irradiation with ultraviolet light (UV). Recent studies with purified DNA polymerase from *Escherichia coli* have suggested that this enzyme may play an important part in excision. The homogeneous protein preparation used in these studies, besides possessing DNA polymerase activity, had other catalytic properties, all contained in a single polypeptide chain of 109,000 molecular weight[3]. Kelly *et al.*[4] have shown that *in vitro* the purified preparation exhibits both polymerase and exonuclease activity on UV-irradiated DNA in which nicks were introduced with pancreatic deoxyribonuclease. The result of these activities is that the nicks are translated in the 5′→3′ direction and oligonucleotides that contain dimers are excised. Thus the exonuclease has the special function of producing the nick which is required for removal of the oligonucleotide containing the dimer.

As suggested by Kelly *et al.*[4], the "role of DNA polymerase (*in vivo*) would best be demonstrated if a mutant in repair or recombination had a defect in its DNA polymerase". De Lucia and Cairns[5] have isolated a mutant (designated P3478) and identified it not by a defect repair but by the inability of mutant cell extracts to incorporate labelled deoxyribonucleoside triphosphates into DNA. This mutant, which grows normally and has nearly normal recombination ability, is sensitive to inactivation by UV and methyl methane sulphonate[5,6]. We wish to describe the results of a series of experiments designed to determine the cause of the increased UV sensitivity of the mutant.

Cells were grown with aeration to 2×10^8/ml. in tryptone broth (NaCl, 5·0 g; Bacto tryptone, 5·0 g; nutrient broth, 3·0 g; maltose, 2·0 g; H_2O, 1 l.) supplemented with 2 μg/ml. thymidine. Radioactive labelling, when required, was achieved by adding 10 μCi/ml. ^{3}H-thymidine (6·7 Ci per mmole) or 0·5 μCi/ml. ^{14}C-thymidine (59 mCi per mmole). (Both radiochemicals were obtained from New England Nuclear Corp.) Biological assays were made on tryptone agar (NaCl, 5·0 g; Bacto tryptone, 5·0 g; Bacto peptone, 5·0 g; Bacto agar, 12·0 g; H_2O, 1 l.) supplemented with 2 μg/ml. thymine and 1 μg/ml. thiamine. Cultures to be irradiated with UV were centrifuged, washed and resuspended in buffer (Na_2HPO_4, 0·12 g; KH_2PO_4, 0·6 g; NaCl, 0·01 g; NH_4Cl, 0·2 g; $MgSO_4$, 4·54 g; gelatin, 0·1 g; H_2O, 1 l., *p*H 7·0). For irradiation of large numbers of cells, stirred suspensions at 1×10^9 cells per ml. in buffer were irradiated in a thin-layer under a germicidal lamp. The effective UV dose was calibrated retrospectively from the survival of the cells compared with a survival curve obtained in identical conditions with a transparent cell suspension.

DNA synthesis and degradation were measured in terms of changes in acid-insoluble radioactivity. 100 μl. volumes of ^{3}H or ^{14}C-thymidine labelled cell cultures were pipetted on to Whatman No. 3 filter paper disks, which were then washed in ice-cold 5 per cent trichloroacetic acid (TCA), rinsed with ethanol, and dried at 80° C. Radioactivity was counted with a toluene–BBOT counting solution and a Packard 'Tri-Carb' scintillation counter.

Methods for measuring dimer excision and the production of single-strand breaks in irradiated DNA have been described previously[1,7,8]. To limit extensive degradation of the DNA of UV-irradiated P3478 cells before they were ready to be handled, we irradiated the cells in chilled buffer containing 10^{-2} M KCN. The cyanide was removed by centrifugation and dilution of the cells into warm broth at zero time.

The Fate of DNA in Irradiated Cells

The mutant strain is about five times as sensitive as its parent to UV inactivation (Fig. 1). In our conditions the 1/*e* doses taken from the final slopes of the survival curves were 20 and 100 ergs/mm² for P3478 and W3110, respectively.

When cells prelabelled with ^{14}C-thymidine are washed, irradiated with UV, and incubated in growth medium

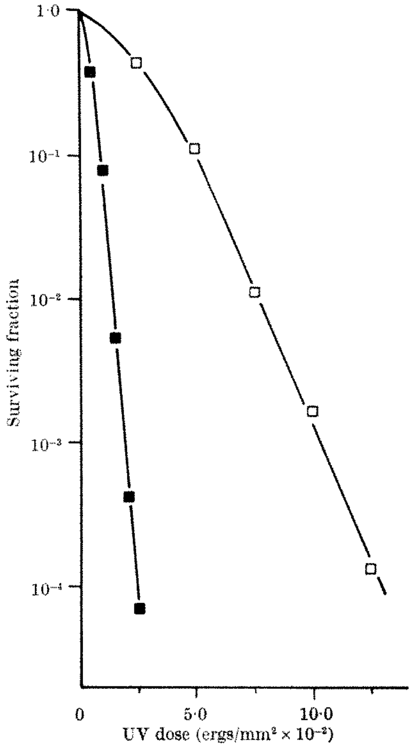

Fig. 1. UV survival curves. Stirred suspensions of cells at 2×10^7 per ml. in buffer were irradiated with germicidal light at 254 nm. □, W3110; ■, P3478.

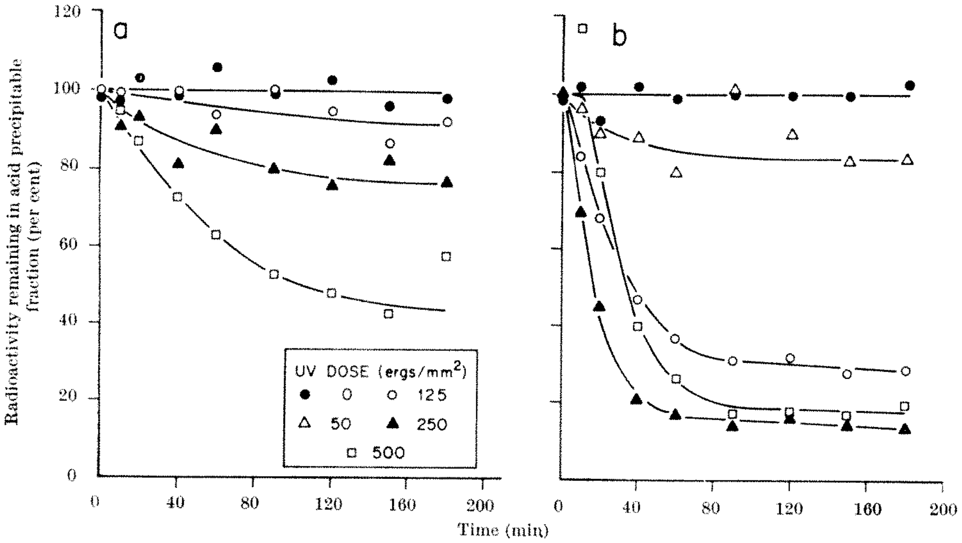

Fig. 2. Degradation of UV-irradiated DNA. Cells which had grown for several generations in tryptone broth + 2 μg per unlabelled thymidine + 0·5 μCi/ml. ^{14}C-thymidine were centrifuged, washed and resuspended in buffer at 2×10^7 per ml. Cells were irradiated with the indicated doses at 265 nm and then diluted into tryptone broth + 2 μg per ml. unlabelled thymidine at 37° C. At intervals, samples were taken and the TCA-precipitable radioactivity was counted. *a*, W3110; *b*, P3478.

containing 2 μg/ml. unlabelled thymidine, it is possible to detect degradation of the DNA (Fig. 2). The high sensitivity of the mutant cells (Fig. 1) is clearly related to the extensive degradation of DNA into TCA-soluble components at low doses (Fig. 2*b*). The DNA of P3478 is degraded faster and more extensively than W3110 DNA after irradiation with the same UV dose. Consequently, incorporation of exogenous label into DNA should be inhibited to a greater extent in P3478 than in W3110, because in the mutant cell population there would be not only fewer intact templates to replicate but endogenous label from breakdown would tend to be incorporated first. The data in Fig. 3 confirm this. Comparison of Figs. 1, 2 and 3 shows that UV doses which produce similar survivals generally cause similar extents of degradation and inhibition of post-UV DNA synthesis. This correlation does not seem to hold for the smallest UV doses; for example, 50 ergs/mm² has a similar effect on DNA synthesis for both strains.

The Excision of Dimers

We determined whether UV-induced pyrimidine dimers remained acid-insoluble following exposure of cells to small UV doses. In the experiments shown in Fig. 4, UV doses from 70–180 ergs/mm² converted 0·03–0·08 per cent of the radioactivity in thymine to thymine-containing dimers, which corresponds to between 300 and 770 dimers per DNA molecule[7]. The initial rate of dimer excision by P3478 is about half that of W3110 but continues longer in P3478, so that by 40 min only slightly fewer dimers have been excised. It is difficult to judge whether these differences in excision kinetics are significant or whether they result from the more extensive degradation of DNA by P3478 seen in Fig. 2. Table 1 is a balance sheet of the radioactivity for experiment 2 of Fig. 4. About 70 per cent of the radioactivity is accounted for, and as dimers are removed from the TCA-insoluble fraction they increase in the TCA-soluble fraction.

Two aspects of these experiments are unusual for the excision of dimers in *E. coli*. A delay of some 5 min is observed before excision commences (Fig. 4) and about 20 per cent of the total radioactivity appears in the growth medium of both cultures after 40 min of incubation (Table 1). Approximately one-half of the radioactivity from W3110 medium and one-third of that from P3478 medium was probably in the form of polynucleotides, because this material was insoluble in 5 per cent TCA and remained near the origin when chromatographed with a butanol–acetic acid–water (80 : 12 : 30) solvent. The remaining activity moved to the position of thymine or thymidine. We conclude that a sizable fraction of the radioactivity in the medium is DNA, probably from cells which have lysed, and presume that both the delay in excision and the lysis of cells occurred as a result of irradiating the cells in the presence of 10^{-2} M KCN.

Clearly the five-fold increase in UV sensitivity of the mutant cells is not the result of a failure to excise dimers, because this defect at most would account for only a two-fold increase in sensitivity. Rather, the increased sensitivity seems to be better explained by the correlated increase in nuclease activity. Alkaline sucrose gradient analyses showed that the average molecular weight of the DNA of UV-irradiated mutant cells was always larger than that expected if one single strand break per dimer was produced. This indicates that DNA degradation in these cells occurred as a result of exonuclease activity, rather than that of a rampant endonuclease. The same data (to be published elsewhere) suggested that although the more extensive degradation of the DNA

of P3478 has the effect of keeping the gaps open for longer times than in W3110, there was probably some repair of breaks even in the mutant strain.

We conclude that an exonuclease activity possessed by P3478, which leads to the degradation of UV-irradiated DNA, masks the excision of dimers, and interferes with the final step in excision-repair, that of restoring the integrity of the phosphodiester backbone of the DNA duplex. The identity of the exonuclease remains obscure. The possibility that there is a mutation in a nuclease other than the exonuclease activity of DNA polymerase seems unlikely at first sight, for extracts of P3478 cells do not inhibit DNA synthesis mediated by extracts of W3110 (ref. 5). The important activity in the excision model based on DNA polymerase is that of the 5′→3′ directed exonuclease[4], which can occur, *in vitro*, in the absence of polymerization[9]. Our results do not contradict this model.

We thank Dr J. Cairns for making available to us the bacterial strains used in this study; and Drs J. K. Setlow, P. A. Swenson and M. L. Randolph for reviewing the manuscript. This research was jointly sponsored by the Science Research Council of Britain (through an SRC–NATO postdoctoral fellowship to J. M. B.) and the US Atomic Energy Commission under contract with the Union Carbide Corporation.

DNA Synthesis *in vitro*

by
DOUGLAS W. SMITH*
HEINZ E. SCHALLER
FRIEDRICH J. BONHOEFFER

Max-Planck-Institut für Virusforschung and
Friedrich-Miescher-Laboratorium der Max-Planck-Gesellschaft, Tübingen

In a new *in vitro* system, DNA is synthesized semiconservatively at rates of chain growth comparable with replication *in vivo*. This DNA synthesis is also observed with a strain of *E. coli*, which lacks DNA polymerase activity *in vitro*.

DNA synthesis *in vitro*, using the classic purified DNA polymerase system of Kornberg[1], differs from replication *in vivo* in several respects. The two most important are that the *in vivo* rate is two orders of magnitude higher than the *in vitro* rate and that no net semiconservative synthesis is achieved *in vitro* with double stranded DNA as template[2]. Furthermore, it now seems likely that DNA replication is mediated by a number of different proteins which may be assembled in a replication complex at the cell membrane. The search for such a complex in its functional state *in vitro*[3-6] is, however, usually complicated by the presence of DNA polymerase, which effectively uses damaged DNA as a substrate for repair synthesis. In this and in the following article[7] we describe two new systems for DNA synthesis *in vitro* which reduce the activity of this unwanted background reaction.

Table 1. CHARACTERISTICS OF THE INCORPORATION SYSTEM

System	dCMP incorporated into acid-insoluble nucleotides during 1 min at 37° C (pmoles/10^8 cells)
Complete	14·5
Minus dTTP	0·4
Minus dATP	0·5
Minus dTTP, dATP	0·3
Minus dTTP, plus dBUTP	14·1
Minus rATP	6·2
Preincubation without 3 dNTPs for 3 min, at 37° C	11·0
Plus pancreatic deoxyribonuclease (50 μg), venom phosphodiesterase (50 units)	
3 min before and during incorporation	0·7
After incorporation	1·2
Minus 0·06 M KCl, plus 0·032 M KPO_4 (*p*H 7·5)	10·1
Minus 0·06 M KCl, plus 0·016 M KP_2O_7 (*p*H 7·5)	1·2

E. coli W 3110 *thy⁻ pol A_1* cells, prelabelled with ^{14}C-thymine (about 300 c.p.m./10^8 cells) were embedded in 2 per cent agar (2–6 × 10^9 cells/ml.). The agar was fragmented; fragments were washed and incubated with aeration at 37° C in a spheroplast forming medium (66 ml./g agar) which consists of 'Penassay' broth containing penicillin (500 units/ml.), 0·5 M sucrose, and 0·01 M $MgCl_2$. After 2 h the agar was collected by filtration and washed five times with 10 ml. of ice cold lysis buffer (0·05 M Tris-HCl, *p*H 7·5, 0·005 M $MgCl_2$, 10^{-6} M tRNA, 5 per cent 'Brij 58'). Agar samples of about 0·05 g were assayed for nucleotide incorporation in 0·2 ml. of a reaction mixture containing 0·05 M Tris, *p*H 7·5, 0·005 M $MgCl_2$, 0·08 M KCl, 10^{-4} M dithiothreitol, 10^{-3} M ATP, 2×10^{-5} M dTTP, dATP, dGTP, 2×10^{-5} M ^{3}H- or α-^{32}P-labelled dCTP (10^3 c.p.m./pmole), and 10^{-4} M deoxycytidine. After 1 min at 37° C the reaction was terminated by addition of 0·1 M EDTA (0·2 ml.). 1 M NaOH (0·5 ml.) was added and the agar was dissolved by heating to 100° C for 5 min. The acid-precipitable radioactivity was determined. The results were corrected for blank values (EDTA added at 0 min) which ranged from 0·5 to 1 per cent of the incorporation of the complete system. ^{14}C-thymine prelabel was used to normalize the incorporation values with respect to the number of cells (except for the nuclease treated samples).

We have tried to develop an *in vitro* system from *Escherichia coli* which maintains the structural integrity of DNA and membrane as far as possible, and which allows removal of the bulk of soluble components, including DNA polymerase. *E. coli* cells are embedded in a matrix of agar, the agar is fragmented, the cells are transformed into spheroplasts within the agar fragments and lysed carefully by osmotic shock. After extensive washing the agar still contains DNA and membranes. On incubation with deoxyribonucleoside triphosphates, DNA is synthesized within the agar fragments in a semiconservative manner. This enzymatic activity differs distinctly from that of DNA polymerase in several respects, and particularly in its rate of chain elongation. The *E. coli* mutant described by de Lucia and Cairns, W3110 *thy⁻ pol A_1*, which lacks DNA polymerase activity *in vitro*[8], was extremely useful in further studies of this system. Only the repair replication was reduced, whereas the other activity remained unaltered. This supports the conclusion that our system characterizes a new DNA-synthesizing activity.

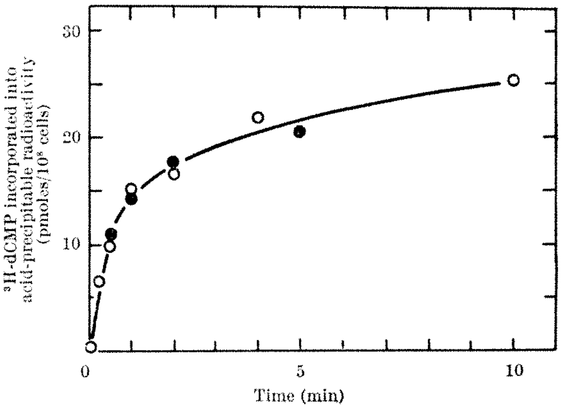

Fig. 1. Kinetics of DNA synthesis. ●, DNA synthesis in the complete system; ○, in the complete system with dBUTP instead of dTTP.

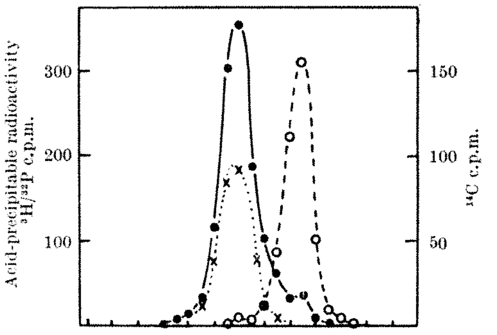

Fig. 2. Density analysis of bromouracil-labelled DNA. DNA was synthesized in 0·5 g agar incubated in 0·75 ml. of the complete reaction mixture with dBUTP replacing dTTP. After 60 s at 37° C, 0·5 ml. of a frozen solution of 0·06 M EDTA and 6 per cent 'Sarkosyl' was added and the agar was dissolved by addition of KI (1·2 g) and heating to 42° C for 15 min. The solution was diluted to 4 ml. and briefly sonicated. KI was removed by dialysis against 0·05 M Tris (*p*H 7·5)–10^{-4} M EDTA. The precipitated agar was removed by centrifugation. 2·8 g of CsCl was added to 2 ml. of the supernatant. The solution was centrifuged for 48 h at 37,000 r.p.m. in the Spinco 'SW 50' rotor. Acid-precipitable radioactivity was determined in fractions after a 4 min incubation at 100° C with 1 M NaOH (0·5 ml.). ○ - - - ○, ^{14}C prelabelled DNA; ●—●, ^{3}H DNA synthesized *in vitro*; × · · · ×, ^{32}P hybrid (bromouracil/thymine) DNA reference.

---

* **Present address:** Department of Biology, University of California, San Diego.

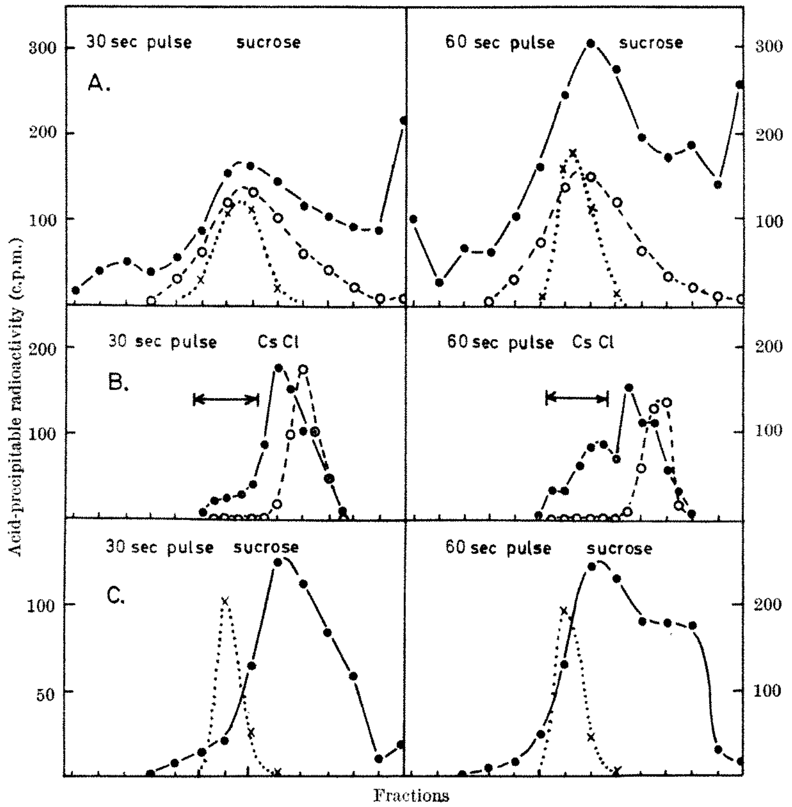

Fig. 3. Size determination. DNA was synthesized in the presence of dBUTP for 30 and 60 s. Except that sonication was replaced by mild shear the procedure was essentially as described in the legend of Fig. 2. *A*, Sedimentation analysis of a fraction of the sheared DNA. A sucrose gradient of 20 to 5 per cent sucrose in 0·01 M Tris and 2 M KI was layered on top of 2 ml. saturated CsCl. All solutions contained low molecular weight DNA (100 μg/ml.) and 'Sarkosyl' (0·1 per cent). Sedimentation was carried out in the Spinco 'SW 41' rotor for 13 h at 20° C and 30,000 r.p.m. The direction of sedimentation is from right to left. *B*, CsCl density gradient. The sheared DNA was separated from the agar by centrifugation into a cushion of CsCl. The CsCl concentration of the DNA containing fraction was adjusted to 57 per cent. After centrifugation in the 'SW 39' rotor at 30,000 r.p.m., 20° C for 48 h, fractions were collected and acid-insoluble radioactivity was determined in a sample of each fraction. The fractions containing hybrid DNA were pooled as indicated by the arrows. *C*, Sedimentation analysis of hybrid DNA. The hybrid DNA obtained from the above density gradient was dialysed against 10^{-2} M Tris (*p*H 7·5) 10^{-4} M EDTA. Sucrose gradients were prepared as described for *A* except that 0·5 M NaCl was used instead of 2 M KI. Centrifugation was carried out in the 'SW 41' rotor for 5 h at 20° and 36,000 r.p.m. ○ - - - ○, ^{14}C-prelabelled DNA; ●—●, ^{3}H-DNA synthesized *in vitro*; × ··· ×, ^{32}P-labelled fd DNA reference. Its sedimentation coefficient is $s_{20,\,w} = 31$S, determined in our conditions in an analytical ultracentrifuge.

Synthesis of DNA

Experimental details of the system are described in the legend to Table 1. The system shows properties expected for template dependent DNA synthesis *in vitro* (Table 1). Synthesis requires all four deoxyribonucleoside triphosphates and the product is sensitive to degradation by deoxyribonuclease. α-^{32}P-dCTP is incorporated just as well as ^{3}H-dCTP. Pyrophosphate ions inhibit the incorporation while phosphate ions have little influence. This suggests that deoxyribonucleoside triphosphates are the precursors for the DNA synthesized. The system is accessible to deoxyribonuclease during incubation. This finding, and the incorporation of α-^{32}P-labelled nucleotides, indicate that the incorporation takes place *in vitro* rather than in any non-disrupted cells.

Mg^{2+} is essential for the activity of the system. Excess EDTA inhibits the system reversibly, whereas the same amount of ethylene glycol-*bis*-(2-aminoethyl ether)N,N'-tetraacetic acid (EGTA) has no influence. The dependence of the described enzymatic activity on *p*H, ionic strength, Mg^{2+} concentration, temperature and especially on ATP is quite different from that of the activity of purified DNA polymerase. These differences do not prove, however, that the synthesizing enzyme is different from DNA polymerase. They might rather reflect properties of other enzymes present in the crude system and which are indirectly involved. The optimal conditions for the system are given in the legend to Table 1 and closely resemble intracellular conditions.

When repair replication by DNA polymerase is avoided by using the polymerase-negative mutant, the agar procedure is unnecessary, for DNA synthesis is observed even in ordinary lysates of spheroplasts. Shear by vortex-mixing has only little influence, whereas extensive breakage by sonication reduced this synthesis by at least a factor of ten.

DNA synthesis levels off after 1 to 2 min at 37° C (Fig. 1). The reason for this is not yet known. It seems unlikely that the short lifetime of the system is the result of exhaustion of precursors or heat inactivation. Repeated addition of 5'-deoxyribonucleoside triphosphates during incubation and preincubation of the system at 37° C without deoxyribonucleoside triphosphates has little influence on the final amount of DNA synthesized. The initial rate of synthesis calculated from incorporation after 30 s corresponds to the incorporation of 5×10^5 nucleotides per min per spheroplast.

Characteristics of DNA Synthesis

To demonstrate semi-conservative synthesis, bromodeoxyuridine triphosphate (dBUTP) was used as a density label: dTTP can be replaced by dBUTP without a reduction in DNA synthesis (Table 1 and Fig. 1). This is to be expected, for *in vivo* dBUTP and dTTP seem to be equally suitable for DNA polymerization (unpublished results of H. E. S. and Voss). The DNA synthesized *in vitro* in the presence of dBUTP instead of dTTP was broken by sonication and analysed in CsCl density gradients. The newly synthesized material had the hybrid density expected of semiconservatively synthesized DNA, which consists of one old light strand and one heavy strand containing the ^{3}H label (Fig. 2). On denaturation, these strands separate in a CsCl gradient and band at positions of heavy and light single strands. As Dr Herrmann has shown, the amount of the parental DNA which is transferred to hybrid density is about 0·5 per cent.

The rate of chain elongation can be calculated from the size of the pieces of newly synthesized DNA and the time required for their synthesis. To determine the size, DNA was synthesized in the presence of dBUTP for 30 or 60 s. The agar was dissolved in KI and the solution sheared. Sedimentation analysis of the sheared DNA showed a broad distribution of molecular weights (Fig. 3*A*). The average molecular weight is about 3×10^7 daltons as calculated from the sedimentation coefficient of 30S (ref. 9). To determine the size of the newly synthesized hybrid molecules the DNA was first removed from the agarose by a preparative sucrose gradient centrifugation and collected on a CsCl cushion. It was then subjected to CsCl density gradient centrifugation. The density distribution is shown in Fig. 3*B*. That fraction of the newly synthesized DNA which banded at the position of hybrid DNA was analysed for size distribution in a sucrose gradient (Fig. 3*C*). The largest molecules which had banded at hybrid density sedimented at about 30S, which corresponds to a molecular weight of 3×10^7 daltons. When the sheared DNA was denatured and the heavy single strands were isolated from a CsCl density gradient, the largest molecules found had the same sedimentation rate as denatured λ DNA (which has a molecular weight of 15×10^6 daltons). From these data the rate of chain elongation is calculated to be $1{\cdot}5 \times 10^3$ nucleotides per second—very close to the rate of DNA replication *in vivo*[10].

The size distribution of the hybrid DNA (Fig. 3*C*) does not permit an exact calculation of the average size of the newly synthesized piece of DNA, mainly because the selection of hybrid DNA is a preferential selection of small molecules. As expected, the average sedimentation velocity of ^{3}H-labelled DNA which bands at light density was greater than that of hybrid DNA.

The rate of total incorporation (5×10^5 nucleotides/min/spheroplast) is about five times higher than the estimated rate of chain elongation (10^5 nucleotides/min). If all the DNA were synthesized at a rate of 10^5 nucleotides/min, the rate of total synthesis could be explained by synthesis at two to three growth points. This number is not unreasonable. There may well be more growth points per spheroplast, but, on the other hand, not all of them might be active in the *in vitro* system.

Relationship with Replication *in vivo*

Our *in vitro* system can synthesize DNA at rates comparable with replication *in vivo*. The total amount synthesized *in vitro* within 1 min is of the same order of magnitude as the amount of DNA synthesized *in vivo* by replication within the same time. Although DNA synthesis continues for only about 1 min, the short lifetime of the system seems less disturbing because the size of the DNA which is copied within this time is very large and corresponds to 10^5 base pairs. It has not yet been shown that both DNA strands are synthesized in this system or that DNA synthesis really occurs on double stranded DNA. We believe, however, that we are observing a limited continuation of real replication at the original growth point.

This system is still very crude. Preliminary experiments indicate that it may be difficult to purify the synthesizing apparatus, free it from its original DNA and use it for synthesis on external template DNA. As demonstrated by Knippers and Strätling[7], a possible first step in purification is the isolation of membrane fractions which display a similar DNA synthesizing activity.

Because DNA synthesis is also observed in sheared bacterial lysates neither integrity of the bacterial chromosome nor an active swivel mechanism of the kind postulated for replication[11] can be necessary for this kind of DNA synthesis. That DNA synthesis is observed *in vitro* when a DNA polymerase-negative mutant is used does not exclude the possibility that the synthesizing enzyme is DNA polymerase associated with other components in a special complex. The more likely interpretation, however, is that our system makes use of another distinct replicating activity, responsible for replication *in vivo*.

We benefited much from discussions with Dr Alfred Gierer. We thank Dr John Cairns for providing us with his mutant and acknowledge the technical assistance of Miss Hannelore Voss and Miss Irmtraud Nietzschmann. The work was supported by the Deutsche Forschungsgemeinschaft and the US National Institutes of Health.

The DNA Replicating Capacity of Isolated *E. coli* Cell Wall–Membrane Complexes

by
ROLF KNIPPERS
WOLF STRÄTLING
Friedrich-Miescher-Laboratorium der Max-Planck-Gesellschaft,
Tübingen

The only DNA synthesizing activity left in a bacterial mutant lacking DNA polymerase is associated with the cell membrane.

THE DNA polymerase described by Kornberg[1,2] has afforded many clues as to the nature of DNA polymerization, but it is not certain whether it constitutes part of the cellular machinery for the replication of genetic material *in vivo*. Moreover, many of its properties[3] can be explained in terms of a DNA repair enzyme. Attempts to characterize the process of DNA replication in a cell free system by measuring the incorporation of radioactive deoxyribonucleoside triphosphates into acid-precipitable DNA[4,5] have been obscured by the high activity of the DNA polymerase. Some clarification of these difficulties has been obtained, however, by the use of the mutant of *Escherichia coli* described by de Lucia and Cairns, which possesses almost no DNA polymerase activity but nevertheless grows like wild type strains in the usual conditions[6].

We have used the DNA of bacteriophage φX 174 to determine the DNA replicating potential of cell extracts and of cell-wall membrane complexes prepared from a derivative of the DNA polymerase mutant. The various intracellular forms of φX DNA are small enough (mol. wt. $3{\cdot}4 \times 10^6$) to be handled without much danger of breakage. *E. coli* DNA (mol. wt. about 3×10^9), on the other hand, is broken into many pieces during conventional extraction procedures.

Early in the reproduction cycle of phage φX 174, the parental circular double stranded DNA molecule (replica-

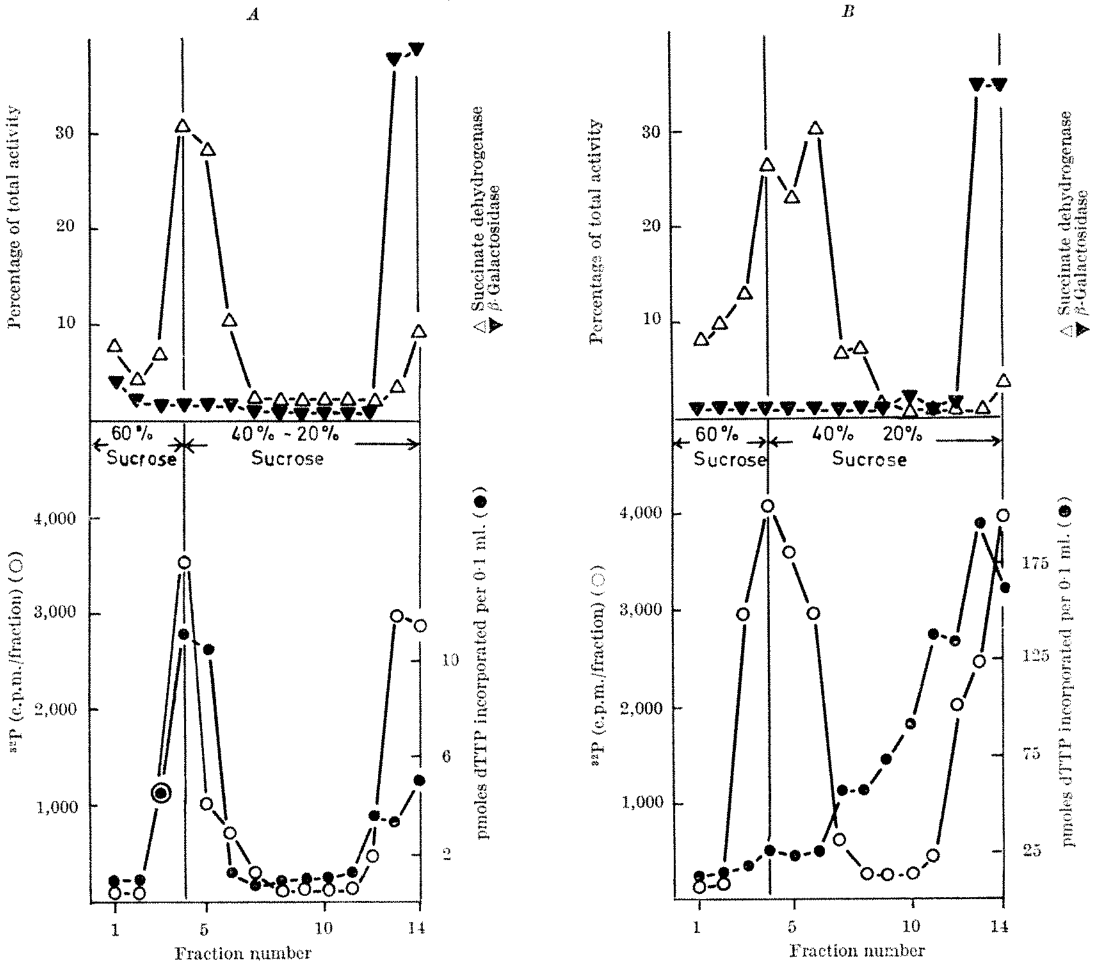

Fig. 1. Sucrose gradient analysis of cell extracts. ^{32}P-labelled φX-infected cells (multiplicity about 6) were lysed as described in the text. A 3 ml. sample of the lysate was then placed on a sucrose gradient. A linear 40 to 20 per cent sucrose gradient was formed above an underlayer of 7 ml. of 60 per cent sucrose. The sucrose solutions were buffered by 0·01 M MOPS (*p*H 7·2)–0·1 M KCl–0·005 M $MgSO_4$–0·0025 M mercaptoethanol. Centrifugation time was 45 min at 25,000 r.p.m. and 2° C in the 'SW 27' rotor of the Spinco centrifuge. Sedimentation is from the right to the left. In aliquots of each fraction the activities of the enzymes succinate dehydrogenase[14] and β-galactosidase (with *p*-nitrophenol-β-galactoside) were tested. The protein concentration was determined by the Lowry reaction[15] (not shown). About 25 per cent of the total cellular protein sedimented with the membrane-wall complex; the remainder was found in the two or three top fractions of the sucrose gradient. A 0·1 ml. sample of each fraction was then mixed with 0·1 ml. MOPS buffer: 0·05 M, *p*H 7·2 containing 5 nmole each of dATP, dGTP. dCTP and TTP plus 0·5 μCi ^{3}H-TTP (9·8 Ci/mmole), 50 nmole ATP and 5 μg "activated" calf thymus DNA. Incubation was for 20 min at 30° C. *A*, Analysis of an extract of about 2×10^{10} ^{32}P-φX-infected *E. coli* H 560 cells; *B*, extract of about $4 \cdot 5 \times 10^{10}$ ^{32}P-φX-infected *E. coli* C cells.

tive form, RF-DNA) replicates semiconservatively to produce circular double stranded daughter DNA molecules (reviewed in ref. 7). We believe that this production of double stranded DNA rings is an example of the ring-to-ring replication, which frequently occurs in microorganisms. We bore in mind, of course, that φX 174 RF-DNA replicates semiconservatively only (1) when one of its composing DNA strands is nicked[8] and an active product of the cistron VI of the phage genome is present[9]; (2) when the replicating DNA is associated with the cell membrane[10]; and (3) when the cellular "replicating apparatus" operates normally[7]. All these conditions are observed by extracting φX 174 infected bacteria gently enough to leave the cellular membrane functionally intact.

Preparation of DNA-membrane Complexes

Exponentially growing *E. coli* H 560 cells (a φX-sensitive derivative of the DNA polymerase mutant of de Lucia and Cairns, kindly supplied by Dr Hoffmann-Berling) were infected with ^{32}P-labelled φX phages in the presence of 30 μg/ml. chloramphenicol. About 20 min later the infected cells were quickly cooled in a methanol solid CO_2 bath, pelleted and washed with a 20 per cent sucrose solution buffered by 0·05 M morpholinopropane sulphonic acid (MOPS)[11] and 0·005 M ethylene glycol-*bis*(2-aminoethyl ether)-N,N′-tetraacetic acid (EGTA)[12] at *p*H 7·0. Between 1×10^{10} and 3×10^{10} cells were then resuspended in 1 ml. of the MOPS–EGTA buffer and treated for 30 min with 50 μg lysozyme/ml. in an ice bath, 0·5 per cent 'Brij 58' (ref. 13) and 0·005 M $MgSO_4$ were then added. After 2–5 min at room temperature the lysate was centrifuged for 45 min through a sucrose gradient (Fig. 1*a*). More than 85 per cent of the *E. coli* DNA and about 50 per cent of the parental ^{32}P-φX-DNA were recovered together with the cell-wall membrane complex as a viscous turbid band floating on top of the 60 per cent sucrose at the bottom of the centrifuge tube. Non-lysed cells sedimented through the shelf. The cell-wall membrane complex was identified by the activity of the enzyme succinate dehydrogenase[14] bound to this structure and by testing for protein[15]. The sucrose gradient fractions containing most of the cytoplasmic material were identified by the presence of the enzyme β-galactosidase (after induction with 5×10^{-4} M IPTG before infection with φX).

Without added primer DNA, radioactive deoxynucleoside triphosphates were incorporated into acid precipitable

DNA preferentially in the "membrane" fractions; after addition of "activated" calf thymus DNA[1] as primer, the polymerizing activity in the membrane fractions did not increase, while a small peak of polymerizing activity appeared in the cytoplasmic fraction of the gradient—probably corresponding to the basic level of DNA polymerase-like activity observed by de Lucia and Cairns[6] in their mutant. Fig. 1*b* illustrates a similar experiment with the common φX host strain, *E. coli* C. After addition of activated calf thymus DNA to the fractions, a much larger DNA polymerizing activity can be detected throughout the sucrose gradient. Its biochemical properties (*p*H optimum, magnesium dependence, insensitivity towards *p*-chloromercuribenzoate and so on) support the conclusion that the incorporating activity in extracts of *E. coli* C which is not associated with the membrane corresponds largely to Kornberg's DNA polymerase. Results similar to those of Fig. 1*b* have been obtained with extracts of a H 560 revertant possessing normal DNA polymerase levels.

Membrane-associated DNA Synthesis

In the experiment of Fig. 2, the DNA polymerizing activity of the wall-membrane complex was followed for a 30 min incubation period at 30° C. Incorporation of ^{3}H-TTP into acid precipitable material started soon after placing the sample at 30° C and continued for 5–10 min. During this time, between 1×10^4 and 3×10^4 thymidine phosphate molecules per cell were polymerized. We do not know why incorporation stops after a few minutes at 30° C. When partially purified DNA polymerase was added to the membrane preparation it was active for at least 30 min, demonstrating that the limited lifetime of the membrane associated polymerizing activity is probably not because the deoxynucleoside triphosphates are exhausted. No conditions have been found to prolong the polymerization time of the membrane system (at a given temperature), and no stimulatory effect by a cytoplasmic component could be observed. A short ultrasonic treatment of the membrane destroyed its synthesizing activity, even if the system was subsequently supplemented with intact φX RF-DNA or highly polymerized *E. coli* DNA. Table 1 summarizes other properties of the membrane system.

Table 1. PROPERTIES OF THE MEMBRANE SYSTEM

	dTTP, incorporated into acid precipitable material (pmoles/10^9 cells)
Complete system*	63
– dATP, – dGTP, – dCTP	< 6
– ATP	40
– Mg^{2+}	< 6
– KCl	23
– Mercaptoethanol	58
+ Pancreatic deoxyribonuclease (15 μg/ml.)	< 6
+ Pancreatic ribonuclease (25 μg/ml.)	62
+ Pronase (10 μg/ml.)	< 6
+ 'Sarkosyl' (0·05 per cent)	< 6
+ 'Brij 58' (0·5 per cent)	63
+ *p*-Chloromercuribenzoate (3×10^{-4} M) mercaptoethanol	8

*0·3 ml. membrane-DNA complexes (corresponding to $2–3 \times 10^9$ cells, see Fig. 1) in 0·01 M MOPS (*p*H 7·2), 0·08 M KCl, 0·005 M $MgSO_4$, 0·0025 M mercaptoethanol were incubated for 30 min at 30° C with 16 nmole each of dGTP, dATP, dCTP and TTP, 0·5 μmole ATP and 1·2 μCi ^{3}H-TTP (9·3 mCi/mole).

At the end of the incubation period (usually after 20 min at 30° C) EDTA was added (final concentration, 0·01 M), and the DNA was extracted with 'Sarkosyl' (Geigy, 'NL-90'; final concentration, 0·5 per cent) and pronase (100 μg/ml.) for 2–4 h at room temperature. After dialysis the DNA was purified by sucrose gradient centrifugation. Between 80 and 90 per cent of the incorporated radioactivity appeared in *E. coli* DNA, and only 10–20 per cent in phage φX-DNA, according to DNA–DNA annealing techniques[16,17]. (A ratio of incorporated c.p.m. (^{3}H) in *E. coli* DNA to those in φX-DNA of about four has been determined, which applies too for chloramphenicol treated φX infected H 560 cells after a 1 min pulse at 25° C with ^{3}H-thymidine *in vivo*: unpublished results of R. K.) Fig. 3 demonstrates that the parental ^{32}P-labelled φX DNA largely remains intact during the preparation and during the incubation period. More than 80 per cent of the parental φX DNA sedimented in two peaks corresponding to the supercoiled form of double stranded φX DNA (RF-I) and to the extended ring form (RF-II), respectively. The remaining ^{32}P label was found as a component of unknown structure floating on top of the CsCl shelf at the bottom of the centrifuge tube, which prevents large DNA pieces from pelleting. When the host cell DNA was prelabelled with ^{14}C-thymine most of *E. coli* DNA was also detected above the CsCl shelf. The ^{3}H-labelled incorporation products appeared predominantly at three places on the sucrose gradient (Fig. 3): (i) on top of the CsCl shelf; this fast sedimenting DNA does not hybridize with denatured φX RF (refs. 16 and 17) and consists most probably of host cell DNA; (ii) a broad peak of DNA pieces sedimenting with rates of about 10S; we find these DNA pieces in experiments with membranes of infected as well as of uninfected cells; (iii) a peak of ^{3}H-labelled DNA detectable only in φX infected cells sedimenting at 16S, frequently with leading shoulders up to 20S. This peak of ^{3}H-labelled DNA hybridizes with φX viral DNA and with an equal amount of denatured φX RF (1·5 to 1·7 times more efficient), indicating that these products consist of both complementary polynucleotide strands of the φX RF.

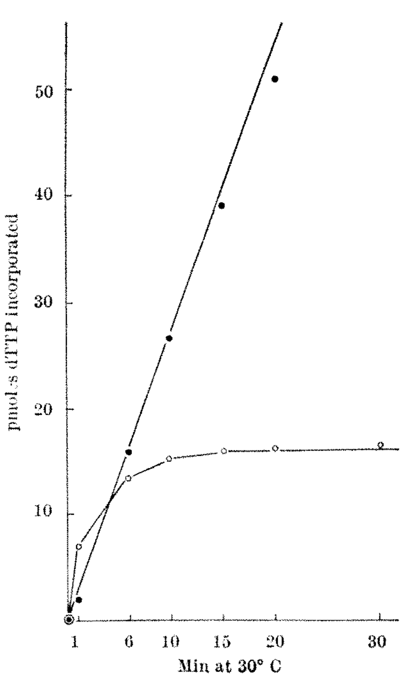

Fig. 2. Kinetics of incorporation of radioactive deoxynucleoside triphosphates into DNA. Preparation of the membrane fractions of ^{32}P-φX-infected *E. coli* H 560 cells is described in the text and in the legend to Fig. 1. To a 2 ml. sample of the membrane preparation in cold 0·1 M KCl–0·005 M $MgSO_4$–0·0025 M mercaptoethanol–0·05 M MOPS buffer deoxynucleoside triphosphates and ATP were added in the same final concentrations and specific radioactivity as in the legend to Fig. 1. Samples of 0·15 ml. were removed at the indicated times after placing the reaction mixture into a 30° C water bath. The ^{32}P radioactivity of a given number of cells was determined before lysis and served as reference. To another 2 ml. sample of the same membrane preparation 0·2 ml. of 5×10^{-3} M *p*-chloromercuribenzoate was added (see Table 1). After 10 min at 0° C, deoxynucleotide triphosphates and ATP were added (see Fig. 1) together with 20 μg/ml. "activated calf thymus" DNA and about 1 unit of DNA polymerase[3]. Incorporation of ^{3}H-TTP into acid precipitable material was linear for 30 min. The *p*H of the reaction mixture was in both experiments adjusted to *p*H 7·2, the optimum for the membrane bound activity. The *p*H optimum for partially purified DNA polymerase in the same experimental conditions is around *p*H 8·1. ○—○, "Membrane system"; ●—●, DNA polymerase.

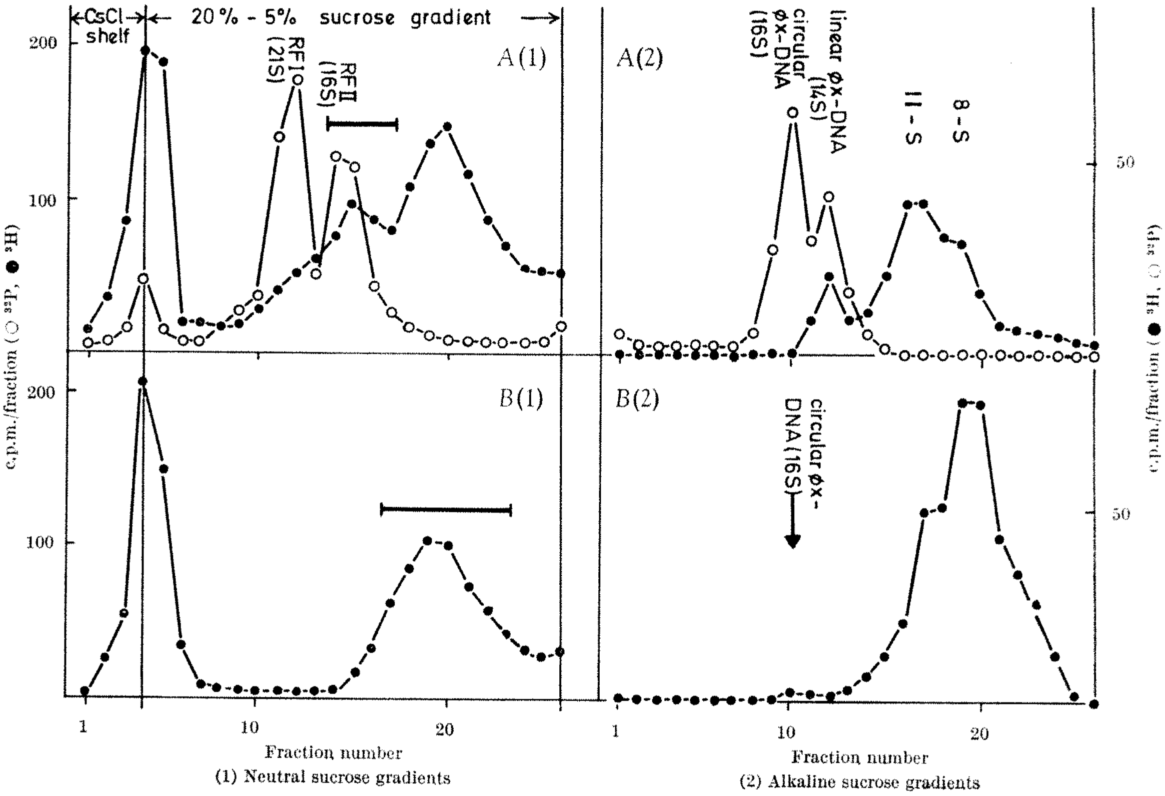

Fig. 3. Sucrose gradient analysis of *in vitro* synthesized DNA. *A*, DNA produced in cell free extracts of ^{32}P-φX-infected cells. (1) The 'Sarkosyl'-pronase extracted DNA was sedimented for 13 h at 4° C at 24,000 r.p.m. in the Spinco 'SW 27' rotor through a 20 to 5 per cent sucrose gradient formed on a 5 ml. CsCl shelf (1·2 g CsCl/ml, 20 per cent sucrose). The sucrose was dissolved in 0·3 M NaCl–0·05 M Tris-HCl–0·005 M EDTA (*p*H 8). (2) Part of fractions 14–17 of the neutral sucrose gradients was recovered, dialysed and denatured with alkali. The denatured DNA was sedimented for 22 h at 27,000 r.p.m. through a 20 to 5 per cent sucrose gradient in 0·01 M EDTA–0·3 M NaOH, *p*H 12·5. *B*, DNA produced in cell free extracts from uninfected cells. (1) Centrifugation conditions: as given. (2) Part of fractions 17–23 of the neutral gradient was recovered and after dialysis denatured with alkali. Alkaline sucrose gradient centrifugation: as above. ^{32}P-labelled φX DNA, extracted from phage particles, served as sedimentation marker. The peak of the 16 S circular φX DNA is marked by the arrow. Sedimentation is from the right to the left.

Phage DNA

A series of experiments in which thymidine triphosphate was replaced by 5-bromodeoxyuridine triphosphate (BUTP, a gift of Dr H. Schaller) and ^{3}H-TTP by ^{3}H-dCTP, respectively, showed that the ^{3}H-labelled φX DNA is the product of an ordered replication process. The φX-specific DNA corresponding to the fractions 14–17 of Fig. 3*A* was recovered from the sucrose gradient and centrifuged to equilibrium in a CsCl gradient (Fig. 4). Three buoyant density classes of DNA can be seen at the end of the equilibrium run: (i) most (80–90 per cent) of the parental ^{32}P-DNA and a small fraction of the ^{3}H-labelled material had the density of a double stranded phage DNA (1·72 g/ml.) of which both strands contain thymine (light–light); (ii) less than 10 per cent of the parental ^{32}P-DNA and 60–70 per cent of the ^{3}H-labelled DNA banded at the buoyant density of a hybrid DNA, composed of one heavy bromouracil and one light thymine containing strand; (iii) roughly 20 per cent of the ^{3}H-labelled incorporation products exhibited the high buoyant density, expected for a double stranded DNA piece of which both strands contain bromouracil instead of thymine (heavy–heavy DNA).

Thus less than one parental RF molecule per cell participates in the semiconservative replication of the membrane system, and replication of φX DNA most often stops after one round of replication. Additional rounds of φX RF replication are initiated only infrequently. In the experiment of Fig. 4, the infectivity of the φX DNA molecules was tested with cells converted to spheroplasts according to Guthrie and Sinsheimer[18]. Most of the infective DNA molecules appear at the fully light position (these molecules were formed in the cell before the lysis); a shoulder of this main peak of infectivity extends into the band of hybrid DNA; and a small but clearly visible infectivity peak corresponds to the fully heavy ^{3}H-labelled DNA. It therefore seems that a small number of intact φX DNA molecules with the complete genetic information of the phage is formed in the membrane system. This result suggests that many of the components necessary for double stranded phage DNA replication are associated with the cell membrane. A possible exception might be a ring closing activity, such as that of polynucleotide ligase, because the largest visible φX specific DNA strand labelled in the membrane system sediments at 14S like a linear φX DNA of one genome length (see Fig. 3*A* (2)). Addition of NAD (10^{-3} M), the cofactor of the polynucleotide ligase[20], with or without cytoplasmic proteins did not change this result. The bromouracil-labelled φX RF-DNAs which are infective are presumably composed of linear polynucleotide strands forming a double stranded DNA circle by means of overlapping complementary single stranded ends.

E. coli DNA

Part of the ^{3}H-labelled *E. coli* DNA (varying in different experiments from 40 to 80 per cent of the total radioactive bacterial DNA) sedimented with most of the parental bacterial DNA and was found at the end of the centrifuge run on top of the CsCl shelf. The remaining ^{3}H-labelled *E. coli* DNA had a sedimentation rate of about 10S

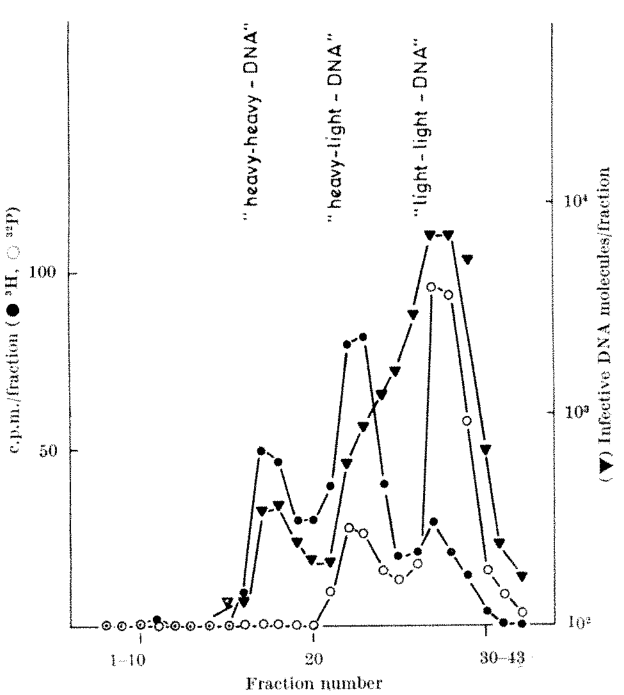

Fig. 4. CsCl equilibrium density centrifugation. A cell free extract of ^{32}P-φX-infected cells was incubated in the conditions described in Table 1, except that TTP was replaced by BUTP and ^{3}H-TTP by ^{3}H-dCTP. The part of the sucrose gradient corresponding to the fractions 14–17 of Fig. 3*A* was recovered, brought to a density of 1·73 g/ml. with CsCl and centrifuged for 55 h at 34,000 r.p.m. in the Spinco 'SW 65' rotor (volume 3·6 ml.). Forty-three fractions were collected, each into 1 ml. sterile Tris-EDTA buffer; 0·05 ml. samples were removed, diluted 1 : 40 into Tris-EDTA buffer and investigated in the spheroplast assay of Guthrie and Sinsheimer[18]. Results are given in relative units: infective DNA molecules/ml. The remainders of the samples were precipitated with 10 per cent trichloroacetic acid on 'Millipore' filters and counted.

(Fig. 3*B* (1)). On alkaline denaturation the 10*S* DNA decomposed into DNA fragments sedimenting at 4·5S, 8S and 11S, respectively. The various fragments were usually identified only as shoulders of the 8S component (Fig. 3*B* (2)). Similar distributions of DNA fragments have been observed in the presence and absence of NAD (10^{-3} M), with or without cytoplasmic proteins. The 10S *E. coli* DNA is double stranded as judged from its buoyant density in CsCl gradients and bands at a density of "hybrid" (bromouracil-thymine) DNA when synthesized with BUTP instead of TTP. It is not yet known whether the 10S pieces in our system are precursors of that fraction of the ^{3}H-labelled *E. coli* DNA which sediments with the macromolecular DNA.

Preliminary estimates for the initial rate of chain elongation in the membrane system are similar to the synthesis rates observed in the agar embedded cells of Smith, Schaller and Bonhoeffer[20]; that is, polymerization of nucleotides proceeds close to the chain growth rates in living cells, although for a very short time period.

Our results demonstrate that much of the DNA replicating machinery is indeed associated with the cell membrane; and that there are at least two functionally different DNA polymerizing activities in the bacterial cell: the "classical" DNA polymerase and a membrane bound "DNA replicase", which may or may not contain the DNA polymerase as an active component. The two DNA synthesizing activities can be distinguished by several criteria. The most striking properties of the membrane system are the very short active period of DNA synthesis, its sensitivity towards *p*-chloromercuribenzoate, and its association with a large cellular structure.

We thank Friedrich Bonhoeffer, Jeffrey Flatgaard and Albrecht Klein for reading the manuscript.

Mammalian Cell Fusion: Induction of Premature Chromosome Condensation in Interphase Nuclei

by

Further evidence is put forward for the inducibility of chromosome condensation, particularly its consequences in interphase cells that are not ready for mitosis.

WE have shown for multinucleate HeLa cells formed by the fusion of cells from different phases of the cell cycle that DNA synthesis and mitosis are inducible[1]. Here we present further evidence for the inducibility of chromosome condensation and the consequences of such an induction in interphase (*G*1, *S*, and *G*2) cells which are not ready to enter mitosis. In heterophasic multinucleate cells formed by the fusion of *S* and *G*2 cells, the initiation of mitosis in one or more of the advanced nuclei resulted in the premature chromosome condensation (PCC) of the lagging nucleus or nuclei. Premature chromosome condensation, which is a kind of atypical mitosis without the mitotic

Table 1. SYNCHRONY IN THE FIRST MITOSIS AFTER CELL FUSION

Type of cell fusion		Binucleate		Trinucleate		Tetranucleate	
		Homophasic	Heterophasic	Homophasic	Heterophasic	Homophasic	Heterophasic
$G1/S^*$	Number of asynchronous mitoses	2^a	1^b	0	0	0	0
	Number of synchronous mitoses	332	83	112	56	25	24
	Per cent of asynchronous mitoses	0·6	1·2	0	0	0	0
$G1/G2^*$	Number of asynchronous mitoses	1^c	0	0	1^d	0	0
	Number of synchronous mitoses	402	70	119	60	25	25
	Per cent of asynchronous mitoses	0·25	0	0	1·6	0	0
$S^*/G2$	Number of asynchronous mitoses	6^e	6^f	0	10^g	0	6^h
	Number of synchronous mitoses	313	49	127	81	51	70
	Per cent of asynchronous mitoses	1·9	10·9	0	11·0	0	7·9

Details of the various types of cells grouped under each superscript are listed below. I denotes interphase; P, prophase; M, metaphase. The digits to the left of the parentheses indicate the number of such cells.

$G1/S^*$ fusion: a: $2(M^*/I^*)$
b: $1(I^*/M)$
$G1/G2^*$ fusion: c: $1(P/I)$
d: $1(2M^*/P)$
$S^*/G2$ fusion: e: $1(P^*/I^*)$; $2(I/M)$; $3(I/P)$
f: $3(I^*/M)$; $3(I^*/P)$
g: $3(2I^*/M)$; $1(I^*/P^*/P)$; $1(I^*/M^*/M)$; $2(P^*/2M)$; $1(I^*/2P)$; $2(I^*/2M)$
h: $1(2I^*/P^*/P)$; $2(2I^*/2P)$; $1(2I^*/2M)$; $1(I^*/M^*/2M)$; $1(I^*/I/2P)$

* Indicates prelabelled nucleus.

spindle, could be readily induced in interphase cells by fusing them with mitotic cells. Induction of chromosome condensation in $G1$ and $G2$ nuclei resulted in the appearance of chromosomes with single and double chromatids respectively, whereas the S nuclei yielded unevenly condensed chromatin.

We used HeLa cells grown as suspension cultures in Eagle's minimal essential medium supplemented with sodium pyruvate, glutamine and 5 per cent foetal calf serum. The culture flasks were gassed with a mixture of carbon dioxide (5 per cent) in air. We have already described[1] the procedures for obtaining synchronous populations of $G1$, S and $G2$ and the technique of cell fusion by UV-inactivated Sendai virus. Mitotic cells prelabelled with ^{3}H-thymidine (0·05 μCi/ml.; 6·7 Ci/mmole) were obtained by treating the cells with colcemide ($6{\cdot}8 \times 10^{-7}$ M) for 19 to 24 h. The method of preparation of the multinucleate cells for autoradiography and the terminology used to describe various types of multinucleate cells are also given in ref. 1. Chromosome preparations were made by giving a hypotonic treatment before the cells were centrifuged on to the slides by cytocentrifuge (Shandon-Elliott). After fixation in 3 : 1 absolute ethanol and glacial acetic acid for 5 min and hydrolysis in 1 N HCl at 60° C for 2·5 min the cells were stained with crystal violet.

Mitotic Synchrony

The incidence of asynchronous mitoses in the first division following cell fusion in multinucleate homo- and heterophasic cells resulting from $G1/S$, $G1/G2$ and $S/G2$ fusions is shown in Table 1. It is clear that in both $G1/S$ and $G1/G2$ fusions the incidence of mitotic asynchrony in the heterophasic as well as in homophasic cells was very small. In the $S/G2$ fusion, however, the incidence of mitotic asynchrony in heterophasic cells was about 10 per cent, significantly greater than that in homophasic cells. Further, the nuclei which first entered mitosis were without exception the $G2$ and not the S phase. The small incidence of mitotic asynchrony in $G1/S$ and $G1/G2$ fusions suggests that these heterophasic components can equilibrate their resources and reach mitosis together[1]. On the other hand, for at least a portion of the population of the $G2/S$ cells, the $G2$ nucleus entered mitosis while the S nucleus remained in interphase. The asynchronous entry of the $G2$ nucleus into mitosis sometimes induced similar changes in the S nucleus producing the phenomenon of premature chromosome condensation (PCC), as shown in Fig. 1. The PCC in multinucleate cells was characterized by the presence of one or more normal sets of chromosomes derived from the $G2$ nuclei along with one or more S nuclei which had undergone irregular condensation of chromatin.

The incidence of PCC was greatest in multinucleate cells containing a large proportion of $G2$ to S nuclei. The greater the ratio of $G2$ to S nuclei (3 : 1 and 2 : 1), the greater was the incidence of PCC of the S nuclei, both initially and throughout the period of investigation (Fig. 2). The greatest incidence of PCC in these cells

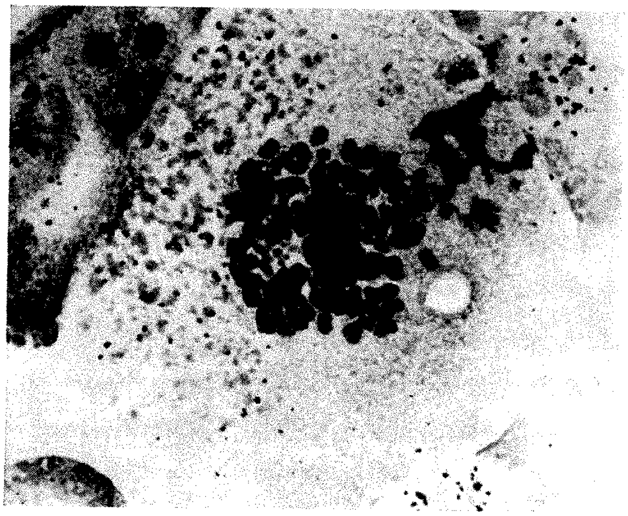

Fig. 1. Premature chromosome condensation in a heterophasic binucleate cell formed by the fusion of S and $G2$ cells. The S cells were labelled with ^{3}H-thymidine before cell fusion while the $G2$ cells were not. The initiation of mitosis in the $G2$ nucleus resulted in the premature condensation of the S-chromatin which could be identified by the silver grains in the autoradiograph.

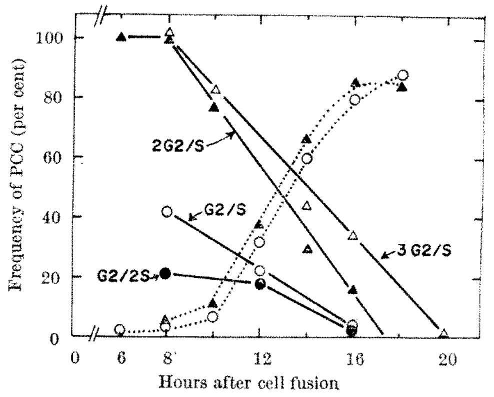

Fig. 2. The frequency of premature chromosome condensation (PCC) in various classes of heterophasic $S/G2$ cells as a function of time after the completion of cell fusion. The S nuclei were prelabelled with ^{3}H-thymidine. The mitotic accumulation functions (represented by the dotted lines) were collected from a different experiment in which colcemide was added immediately after cell fusion between S and $G2$ populations. The data on the frequency of PCC in various classes were collected from a similar experiment to which no colcemide was added following cell fusion. △—△, $3G2/1S$; ▲—▲, $2G2/1S$; ○—○, $G2/S$; ●—●, $G2/2S$. The mitotic accumulation functions for the classes are $2G2/S$ (▲ - - - ▲) and $G2/S$ (○ - - - ○).

occurred when the wave of mitoses was just beginning (see the dotted lines in Fig. 2). This suggests that the most likely multinucleate cells to contain prematurely condensed chromosomes are those that entered division as the earliest of their class. These cells presumably contained an advanced *G*2 nucleus which entered mitosis asynchronously, thus inducing PCC in the lagging "*S*" nucleus. The decrease in the frequency of PCC as a function of time (Fig. 2) indicates that those nuclei of the heterophasic cells which remain in interphase for a longer time after cell fusion have a better chance of achieving mitotic synchrony and consequently a smaller incidence of PCC.

Fusion with Synchronized Cells

The premature condensation of chromatin of the *S* nuclei after the fusion between *G*2 and *S* phase cells strongly suggested that a mitotic inducer was present in either late *G*2 or mitotic cells and that it was capable of pulling a lagging nucleus into mitosis in a dose-dependent manner. In the following experiments synchronized mitotic cells (blocked by either colcemide or N_2O) were fused with synchronous populations of *G*1, *S* and *G*2 cells to see whether mitosis could be induced in these interphase nuclei. When mitotic cells were fused with *G*1 and *G*2 cells, there was a rapid condensation of the

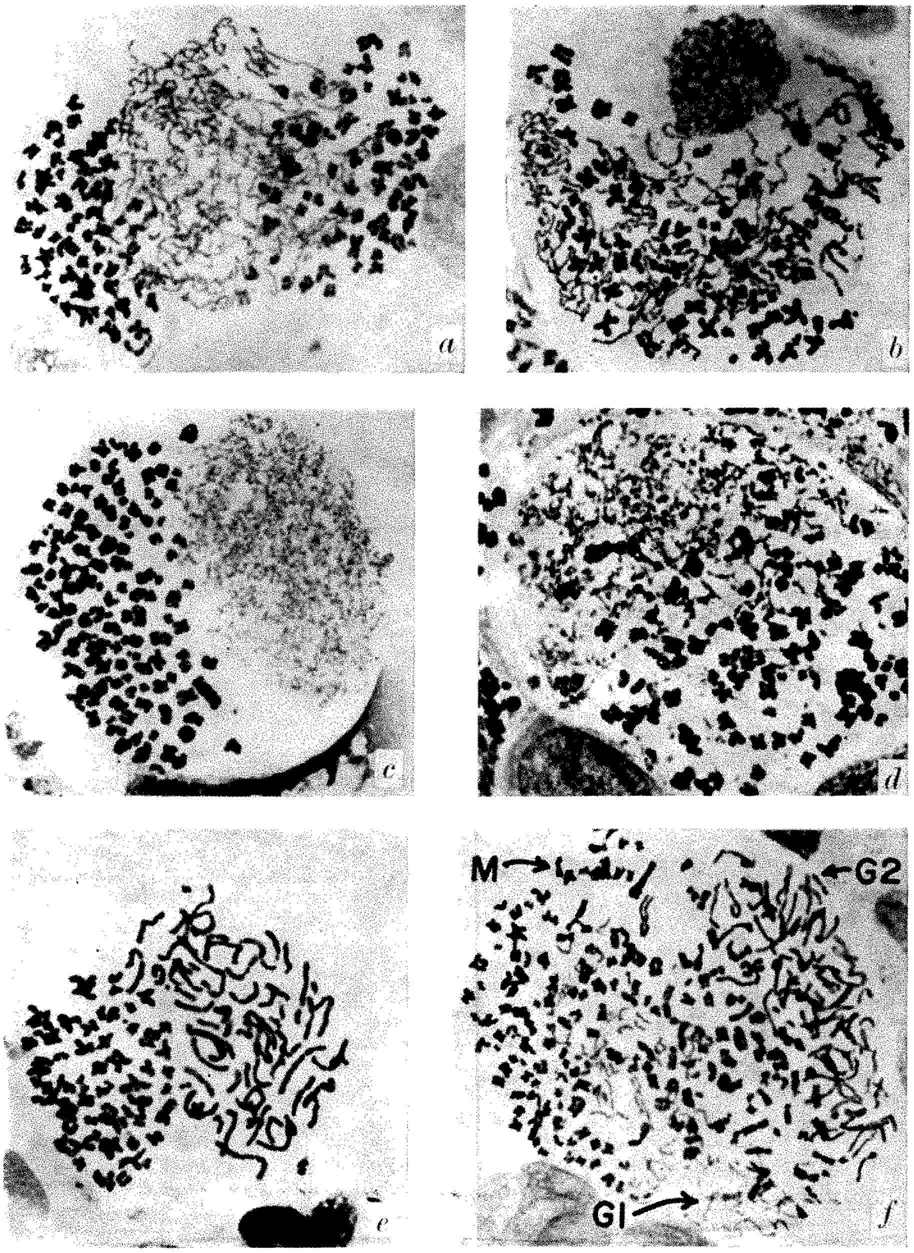

Fig. 3. Premature chromosome condensation in interphase nuclei. *a*, PCC of the *G*1 nucleus in a heterophasic *M*/*G*1 cell at 30 min after the addition of virus. Note the long and slender *G*1 chromosomes with single chromatids. The more condensed chromosomes are from the mitotic cell blocked by colcemide. *b*, Heterophasic cell formed by the fusion of 2*G*1 cells with one mitotic cell. PCC can be observed in the *G*1 nuclei, one of which still shows its nuclear outline. *c*, Premature condensation of the *S* chromatin at 45 min after the fusion between mitotic and *S* phase cells. The chromatin of the *S* nucleus presents a fragmented appearance. *d*, Premature chromosome condensation of a nucleus blocked at the *G*1–*S* boundary by double thymidine treatment. Note that the pattern of condensation is intermediate between that of *G*1 and *S* nuclei. *e*, PCC of the *G*2 nucleus in an *M*/*G*2 heterophasic cell. The more condensed chromosomes are from the mitotic cell treated with colcemide for 19 h. *f*, A heterophasic cell formed by the fusion between *G*1, *G*2 and mitotic cells. Note the differences between *G*1, *G*2 and metaphase (*M*) chromosomes.

The frequency of PCC in various classes of heterophasic cells obtained by fusing mitotic cells with (*a*) $G1$; (*b*) S; and (*c*) $G2$ cells as a function of time. △, $3M/(1G1$ or $1S$ or $1G2)$; ▲, $2M/(1G1$ or $1S$ or $1G2)$; ○ $1M/(1G1$ or $1S$ or $1G2)$; ●, $2M/(2G1$ or $2S$ or $2G2)$; □, $1M/(2G1$ or $2S$ or $2G2)$; ■, $1M/(3G1$ or $3S$ or $3G2)$.

interphase chromatin into chromosomal patterns. The $G1$ chromatin condensed into chromosomes with single chromatids, as might be expected from the unreplicated amount of DNA present (Fig. 3*a*, *b*) and the $G2$ chromatin condensed into chromosomes with double chromatids (Fig. 3*e*, *f*). The S chromatin, on the other hand, usually condensed less completely to form a patchwork of large and small fragments interspersed with material that is hardly condensed at all (Fig. 3*c*). In one of the experiments HeLa cells, blocked at the $G1$–S boundary by excess thymidine (2·5 mM) treatment for 18 h, were fused with mitotic cells. The pattern of chromosome condensation in these interphase nuclei was intermediate between the patterns of $G1$ and S phase condensation (Fig. 3*d*). In these nuclei the degree of chromosome condensation is much greater than in S phase nuclei, but these chromosomes have a more fragmented appearance than those from $G1$ nuclei.

DNA synthesis in the prematurely condensed S nuclei was studied at regular intervals by giving a 15 min pulse treatment with ^{3}H-thymidine (1·0 μCi/ml.; 6·7 Ci/mmole) starting 75 min after the addition of virus. This interval was necessary to achieve the induction of PCC in almost all the heterophasic cells. At 75 min the average number of grains per nucleus was 9·0 for the control (mononucleate S phase cells) and 4·3 for the prematurely condensed S nuclei, indicating that the rate of DNA synthesis in the PCC decreased to 48 per cent of that in the control. At 3·25 h the rate of DNA synthesis in the PCC was only 18 per cent of that in the control. The extent of DNA synthesis in the PCC, as measured by grain counts, was related to the proportion of mitotic to S phase nuclei in the heterophasic cells. The greater the ratio of mitotic to S phase nuclei, the greater was the inhibition of DNA synthesis (Table 2). These data demonstrate that the presence of metaphase chromosomes in the same cytoplasm does not immediately stop DNA synthesis in S phase nuclei, even though marked structural changes have been induced in the replicating chromosomes.

The morphological changes observed in the induction of PCC in interphase nuclei parallel exactly those seen in a normal mitosis. A prophase-like pattern was the first indication of division, and this was rapidly followed by dissolution of the nuclear membrane and the greater degree of condensation of the chromatin into whole or "fragmented" chromosomes according to the position occupied by the affected cell in the life cycle at the time of fusion. There was no sign that the induction of chromosome condensation in these cells was accompanied by the appearance of a mitotic spindle.

Induction of PCC as a Function of Dose

The ability of a mitotic cell to induce PCC in an interphase nucleus depends largely on the ratio of mitotic to interphase nuclei in the cell at the time of fusion. The details of this dose response for three different fusions, $M/G1$, M/S and $M/G2$, are shown in Fig. 4. In each case it is clear that the greater the ratio of mitotic to interphase nuclei, the more rapid is the induction of mitosis and the greater is the proportion of cells in the class that shows induction. Compare, for example, the differences in the speed and extent of mitotic induction between the classes $3M/1G1$ and $1M/3G1$, $3M/1S$ and $1M/3S$, and $3M/1G2$ and $1M/3G2$. From this figure it is also evident that PCC could be induced far more readily in $G1$ nuclei than in either S or $G2$ nuclei. After 45 min almost all of the cells containing $1M/3G1$ nuclei were induced (Fig. 4*a*). In comparison, none of the $1M/3S$ or $1M/3G2$ cells were induced even after 75 min (Fig. 4*b*, *c*). In general, the initial frequency of PCC in M/S cells was lower than that in $M/G2$ in almost all the combinations.

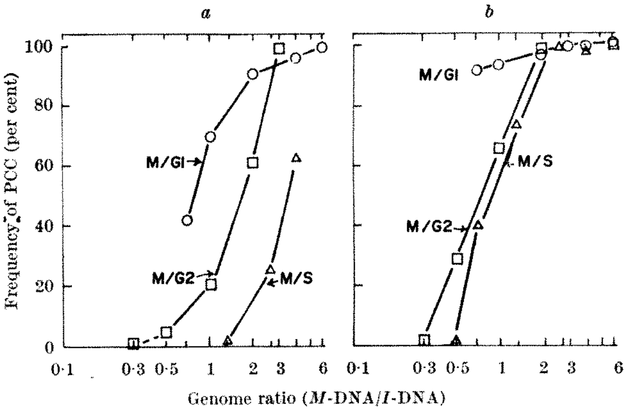

Fig. 5. The frequency of premature chromosome condensation in various heterophasic $M/G1$, M/S and $M/G2$ cells at (*a*) 15 and (*b*) 45 min after addition of virus plotted as a function of the ratio of mitotic DNA to interphase DNA in the cells (genome ratio). The genome ratio is plotted on a log scale. □, $M/G2$ cells; ○, $M/G1$ cells; △, M/S cells.

The data presented so far in Figs. 3 and 4 clearly indicate that the speed and degree of premature condensation of chromatin vary with the position of the interphase cell in the division cycle. The data presented in Fig. 4 were replotted on the basis of the ratios of mitotic to interphase DNA (genome ratios) as shown in Fig. 5. The genome ratios of mitotic DNA to interphase (inducible) DNA were obtained by assuming that a mitotic cell contained two genome units of DNA, while a cell in $G1$ contained one genome unit of DNA. A cell in S phase was assumed to have 1·5 units of DNA, intermediate between $G1$ and $G2$ states.

The derivation of the genome ratios for the various classes of multinucleate cells in each of the three fusions is shown in Table 3. When the frequencies of PCC are plotted against the genome ratios it becomes clear that the susceptibilities for the induction of premature condensation in the $G1$, S and $G2$ nuclei are different (Fig. 5*a*). The induction of PCC in $G1$ nuclei occurs at a smaller genome ratio than in either S or $G2$. At 45 min after the addition of virus the frequencies of PCC in M/S and $M/G2$

Table 2. DNA SYNTHESIS IN PREMATURELY CONDENSED S NUCLEI

	Time (min after addition of virus)	PCC scored $3M/1S$	$2M/1S$	$1M/1S$	$1M/2S$	Total
Per cent incidence of DNA synthesis in PCC (number of cells scored for each class is given in parentheses)	75	20·0 (5)	45·0 (20)	70·6 (48)	100·0 (21)	69·0 (94)

	195	0 (0)	1·0 (2)	3·2 (24)	3·5 (14)	3·2 (40)

Table 3. RATIO OF MITOTIC DNA/INTERPHASE DNA EXPRESSED AS GENOME UNITS*

Ratio of mitotic: interphase cells at the time of fusion	$M/G1$ (genome units)	Genome ratio	M/S (genome units)	Genome ratio	$M/G2$ (genome units)	Genome ratio
3 : 1	$3 \times 2/1$	6·0	$3 \times 2/1{\cdot}5$	4·0	$3 \times 2/2$	3·0
2 : 1	$2 \times 2/1$	4·0	$2 \times 2/1{\cdot}5$	2·7	$2 \times 2/2$	2·0
1 : 1	$2/1$	2·0	$2/1{\cdot}5$	1·3	$2/2$	1·0
1 : 2	$2/2 \times 1$	1·0	$2/2 \times 1{\cdot}5$	0·66	$2/2 \times 2$	0·5
1 : 3	$2/3 \times 1$	0·66	$2/3 \times 1{\cdot}5$	0·44	$2/3 \times 2$	0·33

* One genome unit is defined as the average amount of DNA in a $G1$ cell.

cells were similar but still much smaller than in $M/G1$ cells (Fig. 5*b*). Are there any differences in the susceptibility to induction of PCC of $G1$, S, and $G2$ chromatin when the genome ratios

$$\left(\frac{M\text{–DNA}}{I\text{–DNA}}\right)$$

are identical? For example, the genome ratio of the $1M/2G1$ cells is the same

$$\left(\frac{M\text{–DNA}}{I\text{–DNA}}\right) = 1$$

as that of $1M/1G2$ cells, but their degree of susceptibility was significantly different. Differences in the susceptibilities were also observed between $2M/1G1$ and $3M/1S$ cells, both of which have a genome ratio of 4 (Table 3 and Fig. 5*a*). This suggests that the induction of premature chromosome condensation in interphase nuclei does not depend solely on the amount of interphase chromatin to be condensed.

Support for Hypothesis

The results reported here are consistent with the hypothesis that chromosomal condensation can be induced in mammalian cells. The fusion of interphase cells with those in metaphase usually leads to the condensation of the interphase chromatin within a period of 30 to 60 min. The condensation pattern of the interphase chromatin does not occur randomly but follows the sequence of events of a normal mitosis. The final pattern of condensation of the chromatin depends on exactly which stage of interphase the cell occupied at the time of fusion. The chromatin of $G1$ and $G2$ phase nuclei condensed to form chromosomes with single and double chromatids respectively, but the chromatin of S phase nuclei always condensed into a less clearly defined pattern of light and dark staining fragments. In comparison to the S phase nuclei (Fig. 3*c*), the greater degree of chromosome condensation seen in the cells blocked at the $G1$–S boundary by excess thymidine double block (Fig. 3*d*) suggests that the chromatin in these nuclei is probably primed for DNA replication but is not in an active state of DNA synthesis. Removal of the thymidine block leads to the rapid onset of DNA synthesis and incidentally to the characteristic pattern of S phase chromatin condensation of Fig. 3*c*. This difference in the patterns of condensation between S phase chromatin and either $G1$ or $G2$ chromatin suggests that the state of chromatin during the period of DNA replication is different. The physical state of replicating DNA is different from the non-replicating interphase DNA[2,3]. We show here that condensed S phase DNA is still capable of replication, although at a reduced rate. The inhibition of DNA synthesis in the PCC increased with time and with the proportion of mitotic nuclei in the cells. Presumably these two factors influence the rate and degree of condensation of the S chromatin, reducing the number of replicating sites on the DNA double helix.

The dosage effects observed in the induction of PCC may be provisionally interpreted as a titration of the inducer molecules responsible for the condensation of interphase chromatin. G1 phase nuclei are most readily induced into PCC. Even when there were three G1 nuclei and a single mitotic nucleus, at 30 min after completion of fusion 90 per cent of the cells showed complete induction in all the $G1$ nuclei. S and $G2$ phase nuclei were, however, less easily induced and, in a similar 3 to 1 ratio, there was no induction. These differences in the speed and completeness of induction of PCC in $G1$ nuclei on the one hand and the $G2$ or S nuclei on the other suggest that as the amount of DNA per interphase nucleus increases the amount of mitotic inducer must be increased to produce an effect. Even when the mitotic inducer is present in large quantities the induction of S or $G2$ nuclei requires longer periods of time to be accomplished. In multinucleate cells containing a large proportion of interphase to mitotic nuclei there was no mitotic induction. In an attempt to study the effect of PCC on the division of the mitotic cells, interphase cells were fused with mitotic cells obtained by a reversible nitrous oxide block. When the proportion of interphase to mitotic nuclei was 3 : 1 or greater in the heterophasic cells, the mitotic nucleus became pycnotic. This suggests that the presence of a large number of interphase nuclei can inhibit the completion of nuclear division of a metaphase nucleus, and that this interaction is again dose-dependent.

Mitotic : Interphase DNA Ratio

The induction of premature chromosome condensation in interphase nuclei is related, at least in part, to the proportion of the mitotic to interphase nuclei, and therefore to the relative amounts of mitotic and interphase DNA in the cell. It is probable from Fig. 5, however, that the ratio of mitotic DNA to interphase (inducible) DNA is not the only factor to determine whether the interphase chromatin condenses. It is, for example, much easier to induce a given amount of $G1$ chromatin than it is for an equivalent amount of S or $G2$ chromatin when the genome ratio of DNA is the same in either case. This implies that the mitotic inducer has a much more rapid effect on the chromatin of $G1$ than it has on either S or $G2$ chromatin, and this may be related to the physical state of DNA during the $G1$ period.

When $G2$ and S phase cells were fused together the subsequent mitosis of the heterophasic population was asynchronous in 10 per cent of the cases. In these cells the $G2$ nuclei entered mitosis while the "S" nuclei remained in interphase. In some $G2/S$ cells the entry of the $G2$ nucleus into mitosis had induced the premature condensation of the "S" phase chromatin, indicating the presence of a mitotic inducer(s). It is not clear why there was no induction of premature condensation in all the $G2/S$ multinucleate cells where asynchrony in mitosis was observed.

The premature chromosome condensation reported in the present study is similar to the phenomenon first observed by Stubblefield[5] in multinucleate Chinese hamster cells and later termed "chromosome pulverization" by other investigators[6-11]. We consider that "premature chromosome condensation" describes the phenomenon more accurately. Although PCC is most often associated with multinucleate cells it has also been reported in mononucleate permanent cell lines in culture[12,13]. The incidence of premature condensation has been found to increase with an increase in the ploidy of the cell line[13]. Premature entry of nuclei into mitosis, resulting in aberrant nuclear morphology, has also been observed in *Physarum polycephalum*[14,15]. Guttes and Guttes[14] also found that a proportion of these abnormal mitotic nuclei synthesized DNA. These findings are consistent with the observations of Takagi *et al.*[11] and with the results reported here that prematurely condensed S phase nuclei continue to synthesize DNA, although at a reduced rate.

The prematurely condensed chromatin of $G1$ and $G2$ nuclei is not fragmented or pulverized in the sense that myxoviruses normally damage chromosomes[16,17]. The morphology of the condensed *S* phase nuclei does at first seem to resemble virus-inflicted damage in its pulverized appearance. It is possible, however, that the replicative process of the *S* phase chromatin is entirely responsible for the pattern of its condensation. The inactivated virus used for the fusion seems to have no effect on the induction of premature condensation in interphase nuclei[1]. The induction of premature condensation is not accompanied by the appearance of a mitotic spindle, and it therefore remains to be seen how the prematurely condensed chromosomes are distributed during the subsequent division.

We thank Dr Theodore T. Puck for constructive criticism of our manuscript, and George Barela and David Peakman for technical assistance. R. T. J. holds a Damon Runyon postdoctoral fellowship. The investigation was aided by a US Public Health Service grant from the National Institute of Child Health and Human Development.

Aurignacian Structural Features and Burials at Cueva Morín (Santander, Spain)

by

L. G. FREEMAN

Department of Anthropology,
University of Chicago

J. GONZALEZ ECHEGARAY

Museo Provincial de Prehistoria,
Santander

The discovery of what seems to be the foundation of a hut, an alignment of six post holes, and two graves, one of which contains human remains in a remarkable state of preservation, provides important new information about the earliest Aurignacian occupation of northern Spain.

THE site of Cueva Morín has been known since 1910. Accounts of excavations by the Reverend J. Carballo from 1917 to 1919 and by the Conde de la Vega del Sella between 1918 and 1920 have been published[1,2]. After surveys of prehistoric sites by the Provincial Museum of Santander in 1955 and a sampling programme carried out in Santander and Oviedo in 1962 by one of us (L. G. F., unpublished research), in collaboration with the Seminario Sautuola de Prehistoria y Arqueologia, it was determined that the site would justify renewed excavations. Investigations were begun in 1966 by the Provincial Prehistoric Museum under the direction of J. Gonzalez Echegaray, with the immediate goal of confirming the reported stratigraphy by excavation of the section left along the West cave wall by earlier excavators, and of extending present knowledge of the characteristics of Cantabrian Upper Palaeolithic occupations. Because earlier excavations had stripped the bulk of Upper Palaeolithic occupations from the central and eastern sector of the front of the cave, and Mousterian levels were known to lie near the surface in that area, Cueva Morín seemed an ideal spot to attempt the recovery of large horizontal exposures of Mousterian occupations. In 1968 and 1969 field and laboratory work was carried out under our joint direction. Full accounts of the work will appear elsewhere[3], but we have thought it desirable, in light of the importance of our discoveries, to present a brief résumé of some of the details of our work.

Morín is a critical site for Palaeolithic studies in western Europe and is second to none in Spain in its importance. Among other finds made at the site during 1968 and 1969 are the wall of a Mousterian structure, an extensive Mousterian bone industry (including types strictly analogous with lithic artefacts from Middle Palaeolithic contexts), the first recognized *in situ* Chatelperronian level in the Iberian peninsula, and the subject-matter of this article—an early Aurignacian structural group consisting of an apparent hut foundation, a posthole alignment, and a mortuary complex including two tombs and their appurtenances. Other papers are now in preparation covering the former discoveries, as well as one treating the geological column, by K. W. Butzer.

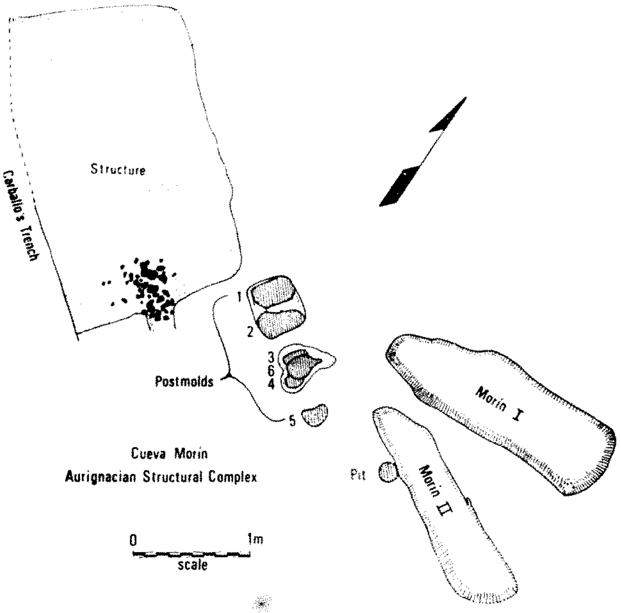

Fig. 1. Aurignacian structural complex, Cueva Morín (drawing).

The Aurignacian stratigraphic sequence at Morin is the only known evidence for the early phases of development of this industrial complex in the Iberian peninsula. It includes six occupation horizons; one assignable to the Aurignacian II stage, two to Aurignacian I and apparently three to Aurignacian "O" (the Perigordian II of Peyrony). The last three levels are designated 8α, 8β and 9, from uppermost to earliest. The characteristic indices[4] for these levels are shown in Table 1. Because the structural complex to be discussed seems to be attributable to level 8α in the general stratigraphy of this site, it is convenient to mention some of the general characteristics of the artefacts from this occupation. The level presents a more typically Aurignacian aspect than do earlier stages in the Aurignacian "O" sequence. Perigordian elements, present in levels 8β and 9, are almost non-existent. There are as many if not more steep (keeled and shouldered) end-scrapers than flat (on flake or blade) endscrapers. Burins are rare and most of them are dihedral, with especially frequent dihedral burins on break. The abundance of *lamelles Dufour* is significant. Judging from the high density of artefacts in this level and the structural complex, occupation during the accumulation of level 8α must have been more intensive than that during the deposition of any other Upper Palaeolithic level at the site.

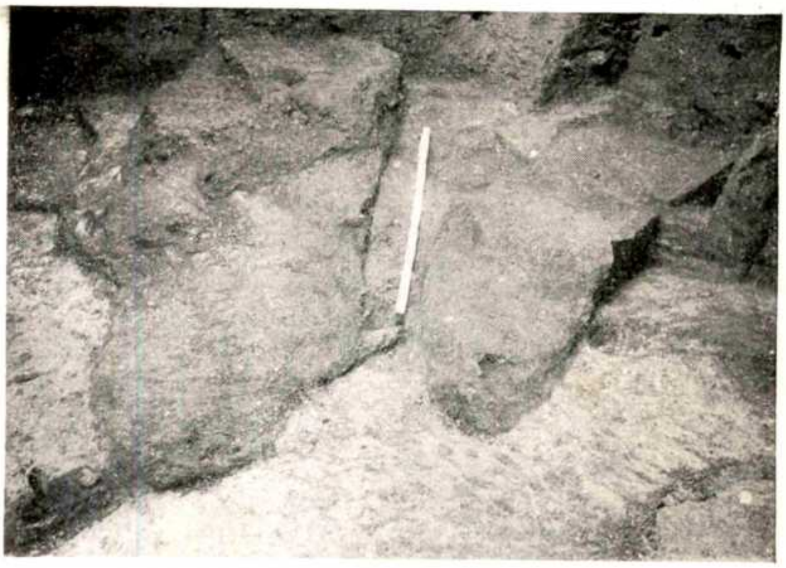

Fig. 3. Mounds atop Morín I and Morín II (seen from west).

The Structural Complex

The stratigraphy of the central and eastern cave sector reveals that the Aurignacian occupants, before the deposition of level 8α or the construction of any of the features, apparently cleared and levelled the cave floor by scraping all accumulated deposits above level 16 (Mousterian of Acheulian tradition) from it. Because level 16 is light in colour, whereas the structural features intrusive into this level are often filled with darker material, those features were first identifiable by the regular dark stains they produced where they contacted the underlying level.

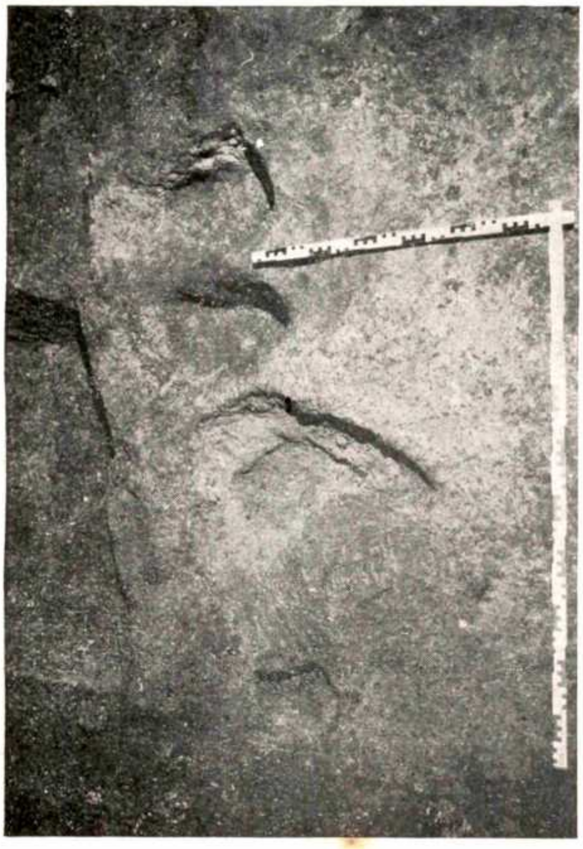

Fig. 2. Posthole alignment and digging stick marks (rule graduated in m).

Table 1. CRITICAL INDICES FOR FIVE AURIGNACIAN OCCUPATIONS AND FEATURES AT CUEVA MORIN

	Levels				Red bed
Index	9	8β	8α	Structure	atop burials
IG	25·3	11·7	24·1	17·2	24·4
IB	9·3	5·8	9·2	8·4	6·6
IBd	5·8	5·8	6·9	4·4	6·1
IBt	0·5	0·0	1·2	1·6	0·0
IGA	9·3	8·8	16·0	4·6	12·3
GA	11·8	11·7	20·6	7·0	14·1
GP	3·4	4·9	0·0	4·7	1·7

The largest feature recovered is the easternmost part of an apparently roughly rectangular excavated depression, measuring approximately 2·6 m on its north-west–south-east axis, and with some 1·7 m of its north-east–south-west axis preserved before a deep trench dug by J. Carballo and extended by the Conde de la Vega del Sella truncates it (Fig. 1). The depth of the standing edges of this pit varies from 27 cm at its northern corner to 3–5 cm along parts of the south-eastern wall. No evidence of postholes or other structural supports was found within or beside the pit, but a distribution of burnt rocks, bone and carbon-rich soil, apparently restricted to a shallow, ovate basin-shaped depression some 35 × 40 cm in diameter, was found inside the south-eastern wall of the structure and is interpreted as a hearth. The basin is joined to a 35 cm long, about 20 cm wide, 6 cm deep trench which slopes upward as it passes to the south-east out of the structure. This part of the feature is interpreted as a draft trench similar to those found attached to some hearths at Corbiac[5]. The large structure did not yield any deliberately constructed superimposed floors and it seems to have been built and used in a single period of activity. This interpretation is partly supported by the fact that stones in the hearth form a continuous distribution from the bottom to the top of the structure fill.

Occasionally, thin laminae of sediment could be traced horizontally over 0·25 m² to 0·50 m² within the fill. These are apparently analogous to laminae produced in fresh deposits added to unexcavated access-ways by the excavators during 1968, when sediment was brought into the cave on workers' feet during the frequent rains. was deposited and

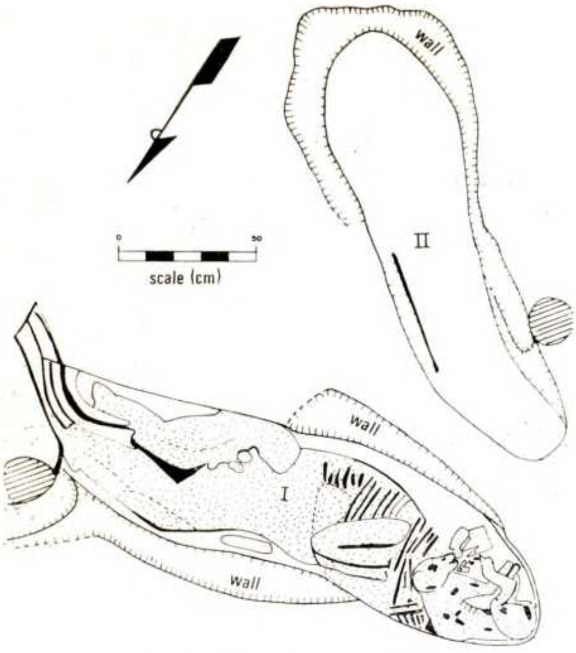

Fig. 4. Morín burials (drawing).

became compacted by trampling as weather dried. Such modern deposition attained a depth of 5 cm during the 1½ month field season in some heavily travelled parts of the site, and if the mechanisms of deposition were similar, it can be suggested that the total depth of laminated Aurignacian structure fill was probably produced during a relatively short period of occupation (perhaps not more than 10 years). The presence of these trampled surfaces and the existence of the hearth suggest that the dugout structure is a hut foundation. It is certainly as large as other features which have been identified as huts or tents by prehistorians, even in its incomplete state of preservation, and similar small structures are known ethnographically as dwellings for nuclear family groups.

Postholes

Starting about 20 cm from the eastern corner of the structure and extending south-east in a rough prolongation of the north-eastern wall of the dugout, an alignment of six pits was discovered in 1968 (Figs. 1 and 2). No wood was recovered from these hollows, but the dark organic stains within them were clearest in a cylinder of earth of less diameter than the pits themselves, while lithic and well preserved bone fragments were abundant surrounding, but not inside, the dark cylindrical stains; this, coupled with the flat-bottomed vertical section of the pits, supports an interpretation of the features as postholes. The character of the stratigraphy of posthole fill and overlying sediments indicates that the (probably wooden) posts were allowed to rot in place, their former cavities being gradually infiltrated with fine sediment. Judging from the size of the cylindrical stains or the diameter of the bases of the postholes, it seems that the maximum possible diameter of emplaced posts could have ranged from 12 to 19 cm.

Details of the structure of the postholes show that posts 1 and 2 (Fig. 1) were set in a single hole and separated by a wall of packed earth fill. Postholes 3 and 4 were also set in a single hole. Only one pile was emplaced in posthole 5. After this post was set, the builders removed posts 3 and 4, replacing them with a single post (No. 6), perhaps to straighten a complex curve in the line formed by the original five posts. No further postholes were recovered during 1969 and it is therefore assumed that the series is complete.

In the process of replacing posts 3 and 4 by post 6, earth removed from postholes 3 and 4 was scooped out of the hole and partially covered posthole 5 (leaving a 12 cm circular area thought to have been caused by the presence at the time of emplaced post 5). The sloping side of postholes 3, 4, 6 produced during this constructional stage bears a series of six well developed shallow arcuate subparallel grooves (Fig. 2). The spacing between adjacent grooves is variable (ranging from about 1·5 cm to about 3·5 cm), as is their depth, which fluctuates between 0·1 and 1·0 cm, and there is no apparent relationship between fluctuations in any set of grooves. These factors suggest that the grooves may have been produced by an excavating instrument with a single, pointed working end. The simplest such implement in modern use is the digging stick. The grooves are not vertical angular striations, but have one wall (the south-western) almost vertical, and the other wall (actually the bottom) inclined at from 70° to 90° to the first. They are all wider towards posthole 5, at the upper end of their trajectory. These observations indicate that the implement was held with point inclined downward, towards the south-west during use, and that the point travelled upward along its trajectory, as would be the case had the tool been used to scoop earth upward out of posthole 4. From the shape of the arcuate grooves and their inclination, one may suppose that the operator was positioned to the north-east of his work, with the implement inclined close to the ground as it would have been had he knelt or squatted by the edge of the pit during work. If the hand that provided driving force was placed high on the shaft of a digging stick used in this fashion, the operator would necessarily have had to be right-handed. The discovery of marks of a Palaeolithic digging implement at Cueva Morín has no parallel of which we are aware in Palaeolithic studies. More such evidence was recovered in 1969.

The Mortuary Complex

South-east of the posthole alignment recovered in 1968, excavations during 1969 revealed the presence of two long tumuli which were recognized as possible human interments. Excavation in the area during the early part of the century was extensive and cut away large sections of both mounds, fortunately without penetrating deeply

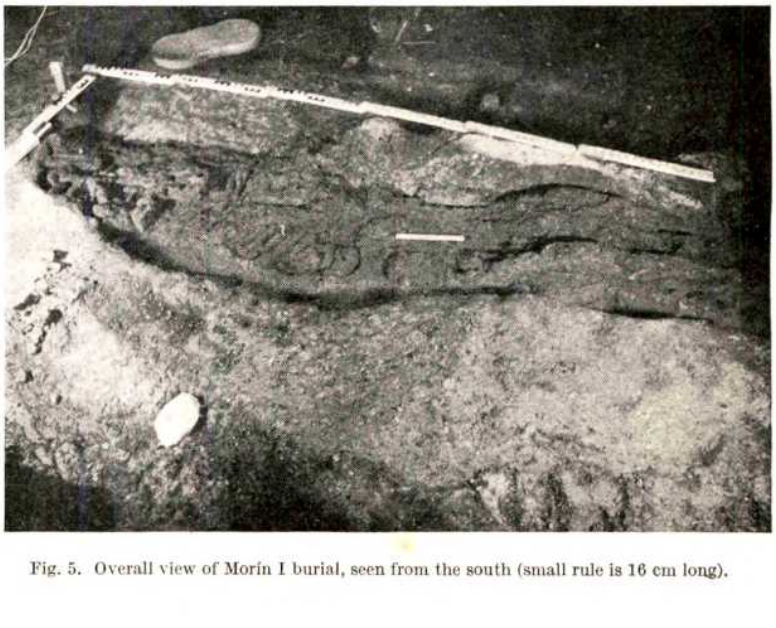

Fig. 5. Overall view of Morín I burial, seen from the south (small rule is 16 cm long).

enough into the strata to disturb the remains of the interments (Fig. 3). The remaining portion of the mound atop Morín I, which was sprinkled with red ochre, measured approximately 115 cm along the axis of the burial, had a maximum width of 75 cm and a greatest height of 44 cm (measured from the surface of the trench containing the burial). The overall length of the mound cannot, of course, be given, but from the length of the preserved mound, coupled with the extent of the burial trench, it is likely to have measured at least 225 cm. Only 57 cm of the mound atop Morín II remained along the burial's long axis; the intact portion was 55 cm wide at its widest point and 40 cm high. The composite length for the standing mound segment and trench was probably about 187 cm. Fig. 1 shows the composite outlines of the intact parts of the tombs and their relation to other structural features.

The tumuli capped two trenches (Fig. 4) which are interpreted as the graves of two individuals. The larger trench, Morín I, has a maximum length of 210 cm and a maximum width of 52 cm, and from foot to head bears S 84° W (mag.). The smaller pit, Morín II, was 168 cm long and 47 cm wide, and bears S 57° E if the heads of the two burials were at the same ends of their respective trenches, or N 57° W if the burials were oriented head to foot. The angle between these bearings is thus either 141° or 39°.

The smaller trench contained no recognizable organic remains other than a dark stain of irregular form in the trench fill. Once the fill had been removed from Morín II, the bottom and sides of the trench proved to be scored with subparallel digging-stick marks like those between postholes 4 and 5.

The larger trench contained human and other remains in a unique state of preservation. As the organic materials in the trench decomposed, their place was taken by fine sediments filtered into the cavities between the remaining organic matter and surrounding deposits, eventually forming a three dimensional mould of the somewhat deformed fleshy parts of the burial and grave goods (Fig. 5). Some (perhaps carbonized) vestiges of organic material are still recognizable in parts of the mould, but on the whole it seems to consist predominantly of fine sediments which are more compact and usually different in colour from the surrounding matrix. The mould is mostly that of a human being of adult stature, lying partly inclined on its left side, in a semi-erect position, with arms positioned before the body and sharply bent upwards at the elbow to bring the hands towards the face. Both the head and the feet are covered by moulds of mortuary offerings. The flesh of the body is represented, and the cadaver has an emaciated appearance which may be the result of deformation by pressures from overlying sediments and decay processes, but may be the result of death by starvation or the wasting effects of disease. The thoracic region is less well preserved than the hips and legs, probably because of relatively rapid decomposition of organs within the body cavity coupled with flattening of the chest and stomach by pressure.

Covering the head of the burial is the exceptionally complete mould of a curled-up small ungulate, lying on its left side, head towards the feet of the burial and front legs tucked between hind legs in the manner in which sheep are still trussed for market (Fig. 6). If this is an adult animal, it must be a roe deer; it could also be a juvenile red deer, caprid or chamois. All these animals are present in the early Aurignacian faunas from Cueva Morín. A number of uninterpretable small moulds were found near the head of this offering and presumably represent other organic grave goods.

The area between the head of the small game animal and the right shoulder of the burial produced several parallel striations which are not a part of the body. They may be remnants of clothing or adornments, but in our opinion their position suggests that they may be the moulds of some binding material such as reeds, hide, or rope used to tie the arms in place in their flexed position during burial. Immediately dorsal to the right upper arm, the ribs of the cadaver form ridges in the sunken flesh. The striations posterior to the ribs are as yet uninterpretable. Part of the body just dorsal to the right elbow was accidentally damaged

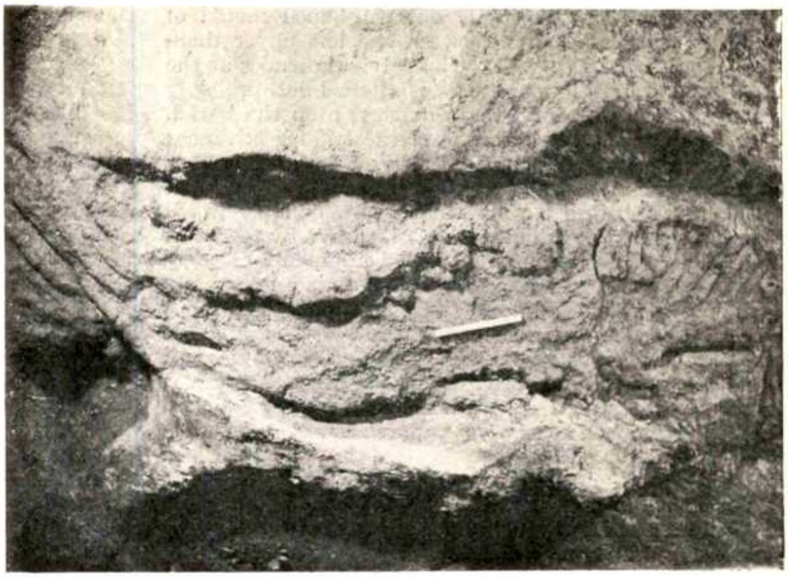

Fig. 7. Detail of pelvic region and legs of Morín I, showing small offering pit at feet and mould of supposed deposit of animal ribs atop foot of trench.

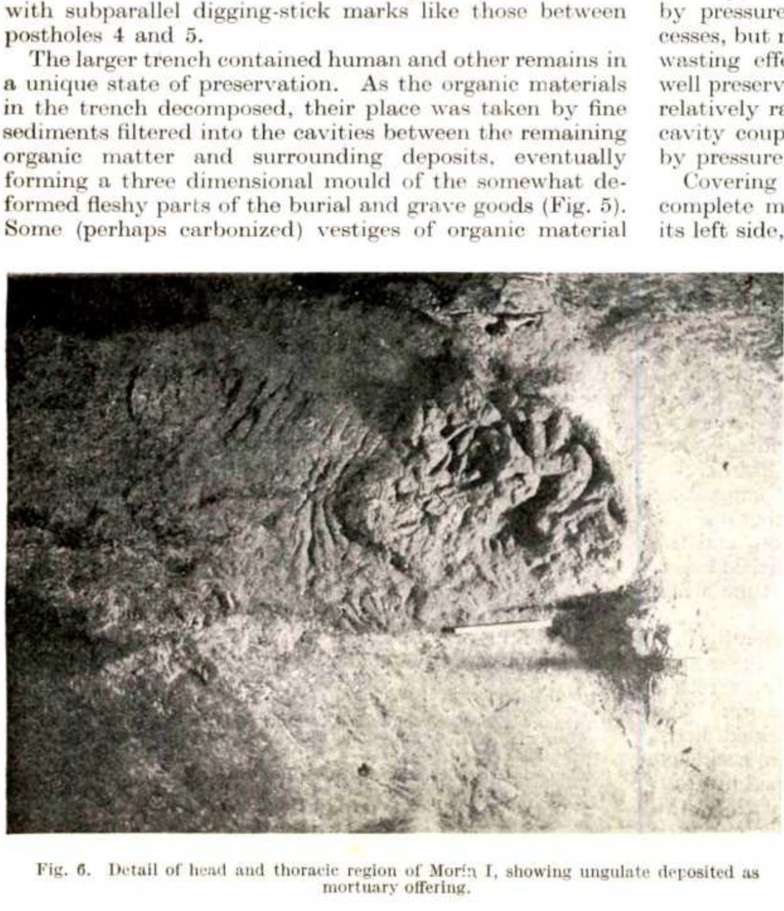

Fig. 6. Detail of head and thoracic region of Morín I, showing ungulate deposited as mortuary offering.

during excavation. A short, sausage-shaped mould of unknown significance lies between the left upper thigh and the grave wall (Fig. 7). The pelvis protrudes at the right hip and both legs are rather flattened out, probably because of the weight of the sediments atop the burial. Both legs are slightly flexed, and the left leg advances before and below the right. The right buttock is very flattened and deformed.

Lying just before the left foot is a small pit which communicates with the interior of the grave by means of a channel. The pit contents yielded fragments of ochre and burnt bone. A similar pit was found in exactly analogous position adjacent to the supposed foot of Morín II; it also communicated with its associated grave and produced similar contents. Beside the offering pit next to Morín II, the negative mould of a Y-shaped wooden or bone object was discovered. A plaster cast removed from the hollow came away containing a well made stone endscraper in a position suggesting that the mould is that of a hafted stone tool. This object may also be related to the mortuary complex. The feet of the Morín I burial are covered by a series of roughly parallel linear moulds, some of which contain bone fragments. These are not restricted to the burial trench but apparently were laid atop the foot of the trench after it had been filled level. They are interpreted as the ribs of a large game animal, but this interpretation is subject to alteration as analysis proceeds. A small fire was lit in a shallow hearth atop the mound covering Morín I and presumably is related to mortuary ceremonial.

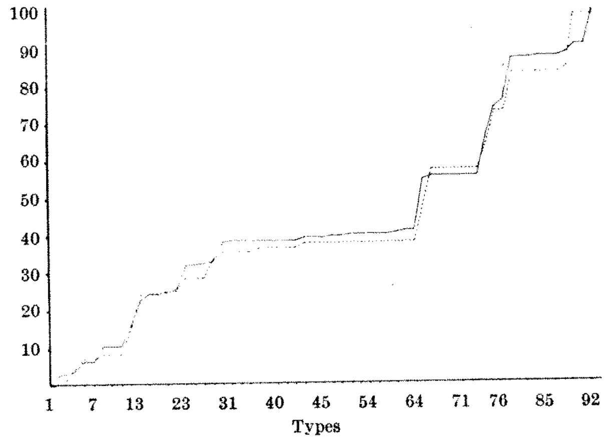

Fig. 8. Cumulative percentage diagram for artefact collections from red bed atop burials (386 pieces) compared with that for level 8α (87 pieces). ———, Red bed; – – – – –, level 8α.

Apparently, while or after the mound was built atop Morín I, the area to its south was deliberately filled with a 20–25 cm deep layer of dark earth. The trench of Morín II was dug through this fill layer, evidence that Morín II is a somewhat later interment than Morín I.

There is, however, stratigraphic evidence suggesting that both trenches and mounds were built during a single construction period of relatively short duration, and the accumulation of the red bed overlying both burials began and continued for an appreciable length of time while both tumuli were completely visible.

Items found in grave fill may be divided generally into two classes—grave furniture and accidental inclusions. No lithic or bone implements recovered from either sepulture can be considered as grave furniture. The trench fills and earth from the mounds yielded lithic artefacts in abundance, but these artefacts were accidentally included in the earth fills which were scraped up from zones of previous occupation. Clods of earth with all the distinctive characteristics of the earlier Mousterian or Acheulian tradition occupation levels at the site were present in both trench fills and mounds. An analysis of the eighty-one retouched pieces from the trench fill of Morín II produces a graph with characteristics to be expected from a mixture of materials from Aurignacian and (mostly Denticulate) Mousterian occupations. Materials from the trench fills and mounds are practically useless in attempts to draw inferences about the material equipment of the tomb builders.

There is no direct connexion between the stratigraphic section in the burial zone and that in the western witness section where the stratigraphic column for Morín is known in most detail. Determination of the approximate stratigraphic position of the burials in our long column must be based on indirect evidence. Because the most recent materials in a fill provide an estimate of the earliest possible date of deposition, the burials are known to be Upper Palaeolithic. Both yielded some pieces out of place in the Morín Mousterian, and the fill of Morín I produced a small, roughly rectangular bone pendant or spatula fragment with tallymarks along both lateral margins. Because the deliberate fill between the trenches and in the mounds contains sediment identical in texture and colour to that in the overlying red bed, it seems that the burials were made after the deposition of a "red bed" was begun somewhere in the cave. No occupation earlier than level 8 is found in sediments with these characteristics. The lithic materials from the red bed overlying the burials produce a cumulative percentage graph (Fig. 8) which is similar to that from level 8α in the stratigraphic column in the western witness section and is quite distinct from the graph for the higher early Aurignacian red level (occupation 6). Thus the burials should be contemporaneous with either level 8β or the earliest phases of deposition of level 8α. Because there seems to be some organic unity in the Aurignacian structural complex as a whole, because the remainder of that complex is quite firmly believed to be contemporaneous with earliest level 8α, and because the burials occupy a stratigraphic position in all ways analogous to the other structural features, we suggest that it is most reasonable to assume that the burials also pertain to level 8α. In any case, no assignment of the burials to any stratum more recent or more ancient than the Aurignacian O levels at Morín can be defended. Carbon-14 dates for the burials may never be determinable, because the mixed nature of burial and mound fills precludes the use of charcoal found within the features for dating purposes. The entire content of the hearth atop Morín I was taken as a carbon-14 sample for assay, but the total amount of charcoal in the sample is small and may be burnt bone rather than burnt wood.

Morín I, jacketed in a fibre glass and plastic box solidly attached to a base of steel, has been removed *en bloc* from the site to the Smithsonian Institition, Washington, DC, for further excavation and the treatment necessary for its permanent conservation. Eventually it will be installed in the Museo Provincial de Prehistoria y Arqueología, Santander.

The burials are the first recognized intentional Palaeolithic interments recovered in the Iberian peninsula, and the structural group is an equally novel find. The discovery of this complex adds an unexpected wealth of detail to knowledge about living conditions and cultural behaviour during the earliest Aurignacian occupation of northern Spain.

A study of the implications of the hypothesis that high energy processes involving cosmic rays acting on the interstellar medium are the sources of the elements Li, Be and B present in stellar atmospheres and in the solar system.

RECENT developments in the observation of L elements (Li, Be, B) in stars and meteorites[1,2] together with progress in studies of the nuclear physics processes involved in the formation of these elements[3,4] make it increasingly hard to hold the view that each star makes its own share of these elements (autogenetic origin). Earlier observational evidence in favour of the autogenetic view has recently either been rejected or made dubious. For instance, the highest abundance values for stellar Li and Be have been shown (Danziger and Vaughan, unpublished, and refs. 5 and 6) to be not larger than the interstellar upper limits ($\mathrm{Li/H} < 10^{-9}$; $\mathrm{Be/H} < 6 \times 10^{-11}$). The missing lithium in the expanding shell of the star T Tauri is still a mystery but probably has nothing to do with the chemical composition of the interstellar medium[7]. Moreover, the variation of lithium and beryllium with spectral class is best explained in terms of destruction mechanisms in the stellar surface (for a review of these questions see ref. 8).

The main difficulty comes from energy considerations. The formation of each L atom requires the acceleration of about 1 erg of fast protons. To account autogenetically for the lithium abundance in T Tauri stars ($\mathrm{Li/H} \simeq 10^{-9}$) the time-integrated amount of energy pumped into particle acceleration must be comparable with the gravitational energy release, implying an unlikely high efficiency for the acceleration mechanism (ref. 9 and unpublished work of Ryter *et al.*).

It therefore seems advisable to consider other sources of the L elements. From the ratios of these elements, one to another, in stars and meteorites, it seems highly probable that the nuclear mechanisms responsible for their generation involve high energy processes (spallation reactions) rather than low energy processes (thermonuclear reactions). Such high energy processes could be due to the action of galactic cosmic rays in their passage through space or at their origin (supernovae explosions, pulsars and so on). In this article we study quantitatively the implications of this hypothesis in particular on the problem of the average intensity of cosmic rays and the solar modulation of the low energy component. We divide the energy range of the galactic cosmic rays into three parts: (1) $E < 5$ MeV nucleon^{-1}, (2) $5 < E < 30$ MeV nucleon^{-1} and (3) $E > 30$ MeV nucleon^{-1}. We find that the lithium abundance is related to the integral flux in region (3) (Φ^{III}) while the boron abundance yields an upper limit on the integral flux in region (2) (Φ^{II}).

Lithium Abundances

The main channels for Li production are: (*a*) p + C,N,O; with a threshold at $E_{\mathrm{p}} \sim 30$ MeV and a mean cross-section of ~ 30 mb, up to the highest energies[3]. (*b*) α + C,N,O; here the centre-of-mass energy is about three times the incident energy per nucleon. The threshold is at ~ 10 MeV nucleon^{-1}. The cross-section is somewhat larger (~ 80 mb) (ref. 10 and Radin, unpublished). (*c*) p,α + Mg, Si; p,α + Fe; the excitation functions rise slowly up to one GeV—above this energy they flatten out reaching values comparable with the corresponding values for C,N,O targets. (*d*) $\alpha + \alpha$; the importance of this reaction was pointed out independently by Hayakawa (unpublished) and Yokoyama (private communication). The threshold is at $E_{\alpha} \sim 12$ MeV nucleon^{-1}. The cross-section rises to ~ 100 mb in the compound-nucleus region (up to a few tens of MeV) and, later on, decreases rather rapidly. A mean value of $\sigma^{\mathrm{II}} \approx 50$ mb is assigned for the region (2), and $\sigma^{\mathrm{III}} \approx 20$ mb at higher energies (region (3)).

Kinetically the L atoms can be formed in two different ways, by the collision of incident light particles on the heavier atoms of the interstellar gas (for instance, fast protons on stationary C, N and O) or the reverse (for instance, fast C, N and O on hydrogen at rest). In the first case the products are essentially at rest, while in the second case they are moving at a velocity comparable with that of the cosmic rays. There are three possibilities for these fast L atoms: (i) deceleration by electron collision, (ii) nuclear destruction by interaction with the interstellar gas, (iii) escape from the galactic disk.

The total inelastic cross-section of L nuclei is approximately 150 mb, corresponding to a mean-free-path of ~ 10 g cm^{-2} against nuclear transformation. This value is comparable with the escape length of galactic cosmic rays out of the galactic disk, as evaluated from various models of cosmic ray diffusion[11].

The deceleration length of fast particles is best studied through the range–energy relationships[12]. For energies below 500 MeV nucleon^{-1} the stopping cross-section of a nucleus of mass A, charge Z and energy per nucleon E (GeV) is conveniently approximated by the expression $\varepsilon = (Z^2/A)[2{\cdot}4 \times 10^{-27} E^{-1}(\text{GeV})]$ cm² GeV, and the range $R = (A/Z^2)[2{\cdot}2 \times 10^{26} E^2(\text{GeV})]$ cm⁻². From this discussion we reach the conclusion that while the L atoms generated by fast protons on stationary atoms are all rapidly thermalized, and become part of the interstellar medium, the L atoms generated by the reverse process have a fate which depends on their initial energy (and hence on the energy of the parent nucleus at the moment of the spallation). L atoms with $E < 0{\cdot}2$ GeV nucleon⁻¹ will effectively be stopped in the galactic gas (and join the initially slow L atoms), while L atoms with $E > 0{\cdot}3$ GeV nucleon⁻¹ will suffer nuclear transformation or escape from the galaxy.

For these initially fast products we define a quantity $f(i+j)$ describing the fraction of L nuclei generated in the process $(i+j)$ which eventually manage to reach thermal velocities in the galaxy. This quantity is, of course, given by the fractional amount of galactic cosmic rays with more than a certain energy, and hence depends on the assumed shape of the cosmic ray energy spectrum. In the spectrum observed at solar minimum the fraction of M ($\varepsilon\Sigma$C to Fe-group) particles with $E < 0{\cdot}25$ GeV nucleon⁻¹ is about 0·2; in a demodulated spectrum the fraction should be larger because the demodulated spectrum is richer in low energy particles than the observed spectrum.

The rate of formation per second of lithium atoms per unit H atom of the galactic gas is given by

$$\begin{aligned} \mathrm{d(Li/H)/d}t = \Phi_{\mathrm{p}}^{\mathrm{III}} & \Bigg\{ \Sigma\sigma(\mathrm{p}+\mathrm{M}\rightarrow\mathrm{Li}) \left[\frac{\Phi_{\mathrm{M}}^{\mathrm{III}}}{\Phi_{\mathrm{p}}^{\mathrm{III}}} f(\mathrm{M}+\mathrm{p}) + \frac{\mathrm{M}}{\mathrm{H}} \right] \\ & + \Sigma\sigma(\alpha+\mathrm{M}\rightarrow\mathrm{Li}) \left[\frac{\Phi_{\mathrm{M}}^{\mathrm{III}}\,\mathrm{He}}{\Phi_{\mathrm{p}}^{\mathrm{III}}\,\mathrm{H}} f(\mathrm{M}+\alpha) + \frac{\Phi_{\alpha}^{\mathrm{III}}\mathrm{M}}{\Phi_{\mathrm{p}}^{\mathrm{III}}\mathrm{H}} \right] \\ & + \sigma^{\mathrm{III}}\,(2\alpha\rightarrow\mathrm{Li}) \frac{\Phi_{\alpha}^{\mathrm{III}}\,\mathrm{He}}{\Phi_{\mathrm{p}}^{\mathrm{III}}\,\mathrm{H}} f(\alpha+\alpha) \Bigg\} \\ & + \Phi_{\alpha}^{\mathrm{II}} \Bigg\{ \Sigma\sigma(\alpha+\mathrm{M}\rightarrow\mathrm{Li}) \left[\frac{\Phi_{\mathrm{M}}^{\mathrm{II}}\,\mathrm{He}}{\Phi_{\alpha}^{\mathrm{II}}\,\mathrm{H}} + \frac{\mathrm{M}}{\mathrm{H}} \right] \\ & + \sigma^{\mathrm{II}}\,(2\alpha\rightarrow\mathrm{Li}) \frac{\mathrm{He}}{\mathrm{H}} \Bigg\} \end{aligned} \qquad (1)$$

where Φ_{p}, Φ_{α}, Φ_{M} are the energy integrated fluxes of particles in space (in the appropriate energy region) and H, He, M are the number densities in the interstellar gas (the most important targets M are C, N, O, Ne, Mg, Si, and iron group nuclei). The factor f (defined previously) is equal to one in the region (2). Let us first compute the value of equation (1) using the flux values observed at solar minimum. Recent measurements are summarized in Table 1.

Table 1. SUMMARY OF RECENT MEASUREMENTS OF GALACTIC COSMIC RAY FLUXES AT SOLAR MINIMUM

	H	He	C,N,O	N	Ne–Si	Fe
Φ^{III} cm⁻² s⁻¹ (E > 30 MeV nucleon⁻¹)	3·6	0·4	25 ($\times 10^{-3}$)	4 ($\times 10^{-3}$)	8 ($\times 10^{-3}$)	2 ($\times 10^{-3}$)
Φ^{II} cm⁻² s⁻¹ (5 < E < 30 MeV nucleon⁻¹)	$\sim 10^{-2}$	$\sim 10^{-3}$				
Abundances relative to H (solar)	1	0·1	15 ($\times 10^{-4}$)	1 ($\times 10^{-4}$)	1·5 ($\times 10^{-4}$)	0·3 ($\times 10^{-4}$)

The proton and helium fluxes at solar minimum are obtained from Freier and Waddington[13] and Comstock, Fan and Simpson[14]. The flux ratio of helium to heavier atoms (known to be almost energy independent down to very low energies) and the recent compilation of Meyer[11] are used to complete the table. Also listed are the solar system abundances (assumed to hold for the interstellar medium).

From the observed galactic cosmic ray spectrum we estimate that $f(\mathrm{M}+\mathrm{p}) \approx f(\mathrm{M}+\alpha) \sim 0{\cdot}2$ while $f(\alpha+\alpha) \sim 0{\cdot}4$ (the lithium energy per nucleon here is only one fourth that of the generating M atom energy).

From Table 1 the fractional contribution of the energy region (2) is negligible and we have

$$\mathrm{d(Li/H)}/\Phi_{\mathrm{p}}^{\mathrm{III}}\,\mathrm{d}t \approx 2 \times 10^{-28}\ \mathrm{cm}^2 \qquad (2)$$

or

$$\mathrm{d(Li/H)/d}t \approx 7 \times 10^{-28}\ \mathrm{s}^{-1} \qquad (3)$$

The L atoms thereby generated become constituents of the interstellar gas, and eventually of the stars formed from it. The photospheric spectral lines of these stars are expected to reflect the galactic gas abundances at the moment of their birth.

Stars are known slowly to destroy their photospheric Li by nuclear reactions in their surface convective zone. The evaluation of their initial Li abundances is best made in young stars (T Tauri type, or members of the Pleiades). To account for lithium abundance in young stars we require

$$\mathrm{Li/H} \sim 10^{-9} \qquad (4)$$

or a total time integrated flux

$$\psi_{\mathrm{p}}^{\mathrm{III}} = \int \Phi_{\mathrm{p}}^{\mathrm{III}}\,\mathrm{d}t = 5 \times 10^{18}\ \mathrm{cm}^{-2} \qquad (5)$$

The necessary average flux over the age of the galaxy ($T_{\mathrm{G}} = 12 \times 10^9$ yr) would be

$$\Phi_{\mathrm{p}}^{\mathrm{III}} = \psi_{\mathrm{p}}^{\mathrm{III}}/T_{\mathrm{G}} = 12\ \mathrm{cm}^{-2}\ \mathrm{s}^{-1} \qquad (6)$$

which is three or four times larger than the present local flux at solar minimum. An analysis of the beryllium abundance yields similar values.

Boron Abundances

The very low threshold for the $^{14}\mathrm{N}+\mathrm{p}\rightarrow{}^{11}\mathrm{C}\rightarrow{}^{11}\mathrm{B}$ reaction ($Q \sim 3$ MeV) can be used to obtain some information on Φ^{II} because no other L isotope can be generated by proton-induced reactions in this energy range. Hence we would expect the $(\Phi^{\mathrm{II}}/\Phi^{\mathrm{III}})$ ratio to have an effect on the $^{11}\mathrm{B}/^{10}\mathrm{B}$ ratio, for instance. We define $^{11}\mathrm{B}^{\mathrm{II}}$ as the abundances of $^{11}\mathrm{B}$ generated in the energy region (2)

$$\begin{aligned} \mathrm{d}\,(^{11}\mathrm{B}^{\mathrm{II}}/\mathrm{H})/\mathrm{d}t = \Phi_{\mathrm{p}}^{\mathrm{II}} & \Bigg\{ \sigma(\mathrm{p}+\mathrm{N}\rightarrow{}^{11}\mathrm{B}) \left[\frac{\mathrm{N}}{\mathrm{H}} + \frac{\Phi_{\mathrm{N}}^{\mathrm{II}}}{\Phi_{\mathrm{p}}^{\mathrm{II}}} \right] \\ & + \Sigma\sigma(\alpha+\mathrm{M}\rightarrow{}^{11}\mathrm{B}) \frac{\Phi_{\alpha}^{\mathrm{II}}}{\Phi_{\mathrm{p}}^{\mathrm{II}}} \left[\frac{\mathrm{M}}{\mathrm{H}} + \frac{\mathrm{He}}{\mathrm{H}} \frac{\Phi_{\mathrm{M}}^{\mathrm{II}}}{\Phi_{\alpha}^{\mathrm{II}}} \right] \Bigg\} \end{aligned} \qquad (7)$$

The average cross-section for $\mathrm{p}+\mathrm{N}\rightarrow{}^{11}\mathrm{B}$ in this region is 120 mb (Epherre, unpublished). For comparison the $(\alpha+\mathrm{M}\rightarrow{}^{11}\mathrm{B})$ in region (3) is ~ 40 mb.

Two observations are of importance here: (*a*) The $^{11}\mathrm{B}/^{10}\mathrm{B}$ ratio in the solar system is much as expected from incident particles in region (3) (refs. 3 and 15). (*b*) The upper limit to the B/Be ratio in the Sun[5] is also close to the spallation ratios in region (3). This leaves little room for

^{11}B formation in region (2). As a rather conservative estimate we take

$$^{11}\mathrm{B}^{\mathrm{II}} < 1/2\ ^{11}\mathrm{B}^{\mathrm{III}} \qquad (8)$$

From equation (7) we obtain

$$\Phi_p^{\mathrm{II}} \leqslant 5\ \mathrm{cm}^{-2}\ \mathrm{s}^{-1} \qquad 5 < E < 30\ \mathrm{MeV} \qquad (9)$$

Abundances of D and ^{3}He

The interaction of galactic cosmic rays with the interstellar gas will generate atoms of D and ^{3}He, chiefly through the p + ^{4}He reaction in region (3). (A smaller amount of D will come from $p + p \rightarrow D + \pi^+$.)

From a ^{4}He cross-section compilation by Meyer[16] we find that a flux capable of generating $\mathrm{Li/H} \simeq 10^{-9}$ will also produce

$$\mathrm{D/H} = 3 \times 10^{-7}$$

and (10)

$$^3\mathrm{He}/^4\mathrm{He} = 3 \times 10^{-6}$$

For comparison the solar system value ($\mathrm{D/H} = 1{\cdot}6 \times 10^{-4}$) is far too high to be explained solely by cosmic rays.

If the solar system value is universal, we could invoke big bang formation (where approximately this value is obtained if 10 per cent of the universal ^{4}He is primordial) or formation by neutron capture in the atmosphere of neutron stars. If the solar system value is local (an upper limit of $\mathrm{D/H} < 3 \times 10^{-5}$ in interstellar space would make us believe that it is), we may have to invoke non-nuclear processes such as the preferential escape of the lighter particles during the evaporation of the early solar nebula.

Because the helium generated by proton thermonuclear reactions has an isotopic ratio $\sim 10^{-3}$, from equation (10) one does not expect cosmic rays to make an important contribution to the ^{3}He production. The initial meteoritic value ($\sim 10^{-4}$) is indeed typical of hydrogen burning (perhaps even somewhat smaller).

Lithium Isotopic Ratio

The ^{7}Li/^{6}Li ratio has been measured in a number of stars[1] and the values range from 2 (the formation ratio) to larger than 10. Preferential destruction of ^{6}Li is easily explained by thermonuclear fusion in the stellar convective zone during the pre-main sequence or the main sequence stages (although some difficulties remain with the ^{9}Be/^{7}Li/^{6}Li ratios).

In the solar system (Earth and meteorites) the isotopic ratio is 12·5. For various reasons it seems difficult to explain the ^{6}Li destruction by thermonuclear reactions in the surface convective zone of the Sun[15,17]. A more promising attempt would involve preferential destruction of ^{6}Li by (p,α) reactions in the matter which was thrown off the Sun to form the solar system. At present, however, it is fair to say that we have no satisfactory explanation of the lithium isotopic ratio in meteorites.

Discussion

To obtain the value of Φ^{III} or the upper limit to Φ^{I} we have neglected lithium destruction by stars. Schmidt's model of galactic evolution[18] predicts an overall destruction rate which is too small to affect our conclusions: according to his calculations more than 50 per cent of the galactic gas has never been part of a star.

The difference between the observed flux above 30 MeV (Φ_p^{III}(obs)) and the time average flux deduced from L element abundances (Φ_p^{III}) can be ascribed to three possible effects.

(*a*) Solar modulation. The effect of the "residual" modulation at solar minimum has been calculated by a number of authors from their favourite version of the modulation theory. The ratio $\Phi_p^{\mathrm{III}}/\Phi_p^{\mathrm{III}}$(obs) is found to be $\sim 1{\cdot}2$ (ref. 19), $\sim 1{\cdot}5$ (ref. 20), ~ 7 (ref. 21) and ~ 20 (ref. 22). Clearly a satisfactory theory applicable down to 30 MeV is yet to come. The L element abundance can, in fact, be used to obtain a limit on the solar modulation. In doing so one must realize that by inserting in equation (1) the demodulated flux instead of the observed flux, one must also include the effect of the modulation on f (see the discussion following the definition of f). Indeed, the solar influence exerts itself mostly on the low energy nuclei. The fraction of decelerating L nuclei should accordingly be increased. As a result, a time integrated flux $\sim 3 \times 10^{18}$ particles cm^{-2} would probably be enough to generate the correct amount of L nuclei.

(*b*) Spatial clumpiness of the high flux regions. The fluxes in the vicinity of the sources (supernovae, pulsars, flare stars, and so on) are likely to be of much higher intensity than in an average galactic location. (The L atoms would later diffuse in space.) Such hot spots could in principle be detected from the accompanying X- and γ-ray emission.

(*c*) Time variation. The time constancy of galactic cosmic rays has been verified only for the last billion years or so (8 per cent of the galactic life). We have serious reasons to believe that star formation and nucleosynthetic processes were much stronger in the early days of the galaxy[23]. A similar evolution could well have taken place for the galactic cosmic rays. It may indeed turn out that most of the L elements were made during this initial epoch of strong stellar activity.

The analysis of the ^{11}B/^{10}B ratio shows that the flux of galactic cosmic rays is not heavily concentrated in the low energy region, at least for energies as low as 5 MeV. This statement has a bearing on the problem of the heating of HI regions and on the emission of galactic gamma rays. These questions will be treated later.

We thank A. G. W. Cameron for pointing out problems in the efficiency of autogenetic acceleration mechanisms, B. Peters (who first suggested to us the possible role of the low energy cosmic rays in generating the L atoms), Yash Pal for discussions of cosmic ray phenomena, and G. R. Burbidge, D. D. Clayton and J. P. Meyer for comments.

Planetary Companions of Pulsars

THE recent observation of a "quasi-sinusoidal" period variation in the pulsar NP 0532 has been attributed to perturbations produced by a planetary companion with an orbital period of about three months and a minimum mass of 1·0 $M_\oplus$ assuming the mass of the pulsar to be 1 $M_\odot$ (ref. 1). It is therefore desirable to investigate the orbit of a planet after a supernova explosion of the central star, and the effect of the new orbit on the observed period of the pulsar.

I will assume that before the explosion all planets were in circular, coplanar orbits. The evolution of the orbit is caused chiefly by the loss of mass by the central star and not from the impact of the expanding shell which for an inelastic collision gives the planet an outward velocity

$$\Delta V_p = V_s \frac{\Delta M}{m} \left(\frac{S}{2r_0}\right)^2 \tag{1}$$

A shell velocity $V_s = 10^4$ km s^{-1} and mass $\Delta M = 1$ $M_\odot$ with planet parameters $m = 1$ $M_\oplus$, $r_0 = 0{\cdot}4$ AU, and $S = R_\oplus$ gives $\Delta V_p = 1{\cdot}5$ km s^{-1}. Because the orbital velocity is about 50 km s^{-1} this only produces an eccentricity $e = 0{\cdot}03$. Colgate[2] has recently discussed the conditions necessary for a supernova blastwave to eject a planet.

Because $V_s \gg V_p$ we can assume, for dynamical purposes, that the loss, ΔM, in the original stellar mass, M_0, is instantaneous. This loss decreases the gravitational energy binding a planet to the central star without affecting its kinetic energy. From these considerations we can easily show that the fractional increase in the semi-major axis of all the planets is given by

$$(r/r_0) = 1/2 \left[\frac{M_0 - \Delta M}{1/2\, M_0 - \Delta M}\right] \tag{2}$$

We note that if $\Delta M \geq 1/2\, M_0$ these planets escape. Thus if $\Delta M = 1$ $M_\odot$ in NP 0532, M_0 was at least 2 $M_\odot$, which gives it a main-sequence spectral class of late B or earlier and makes it a population I supernova.

Blaauw[3] found that for a double-star system to dissociate due to a supernova explosion requires that ΔM be greater than half the combined mass of the two stars or $\Delta M \sim M_0$ if the stars have similar masses. In view of the observed high frequency of binary stars and their more stringent dissociation requirements compared with planetary systems, it is curious that no pulsar has been observed with a stellar companion.

While the angular momentum of the planet is unaffected by the explosion, the increase in the semi-major axis causes its eccentricity to assume a new value

$$e = \left[1 - 2\left(\frac{1/2\, M_0 - \Delta M}{M_0 - \Delta M}\right)\right]^{1/2} \tag{3}$$

or

$$\Delta M/M_0 = e^2/(1+e^2) \tag{4}$$

The eccentricity is high for any reasonably assumed $(\Delta M/M_0)$; for example, $e = 0{\cdot}58$ if $(\Delta M/M_0) = 1/4$ and $e = 0{\cdot}77$ if $(\Delta M/M_0) = 3/8$. As e can be determined by observation in a fashion analogous to the determination of the elements of a spectroscopic binary orbit it will be possible to calculate $(\Delta M/M_0)$ for NP 0532.

If there are several planets in the system the large eccentricities result in the overlapping of many orbits if the spacings of their semi-major axes are similar to those in the solar system. This unstable situation will start a new epoch of active dynamical evolution which may lead to the ejection of many of the less massive planets before the survivors settle into new orbits which minimize the effects of their mutual perturbations. The properties of these final orbits are probably similar to those found by myself[4-6] in computer-simulated planetary systems evolved from arbitrary initial conditions even though the initial eccentricities of the post supernova orbits are probably somewhat higher than those that I used. The computer experiments indicated that the four Jovian planets took about 10^5–10^6 yr to evolve into stable orbits under the influence of their mutual perturbations. For less massive planets of the terrestrial type with semi-major axes as small as 0·4 AU the strong gravitational coupling to the central star combined with weak mutual perturbations make it unlikely that their orbits can be radically altered in time scales of less than 10^9 yr. Thus the orbit of the observed planetary companion of NP 0532 may have remained nearly unchanged since the explosion.

It may be possible to attribute the apparently abrupt change of period observed in NP 0532 to the perturbations produced by its planetary companion*. The observed rotational period, P, of the pulsar due to its motion around the centre of mass of the star–planet system is given closely by

$$\frac{\mathrm{d}(P/P_0)}{\mathrm{d}t} = \frac{1}{c}\left(\frac{\mathrm{d}V}{\mathrm{d}t}\right) \tag{5}$$

where P_0 is the observed period in the absence of orbital motion and V is the radial velocity of the pulsar due to its orbital motion. It is evident that the (P/P_0) and V curves are identical except in scale. From the classical equation for the radial velocity of a spectroscopic binary[7] and equation (5) we easily find that

$$\frac{P - P_0}{P_0} = \frac{V}{c} = \left[\frac{(2\pi G)^{1/3}\, m \sin i}{c(1-e^2)^{1/2}\, \tau^{1/3}\, (M+m)^{2/3}}\right] (\cos(\nu + \omega) + e \cos \omega) \tag{6}$$

where τ is the orbital period, $M = M_0 - \Delta M$, i is the inclination of the orbit plane to the line of sight, ω is the longitude of periastron measured from the ascending node, and ν is the true anomaly which is related to the time, t, since periastron passage by the classical equations

$$\tan (1/2)\, \nu = \left(\frac{1+e}{1-e}\right)^{1/2} \tan (1/2)\, E \tag{7}$$

and

$$2\pi\left(\frac{t}{\tau}\right) = E - e \sin E \tag{8}$$

---

* After the draft of this paper had been completed, a preprint of a paper by F. C. Michel with the same suggestion was brought to my attention.

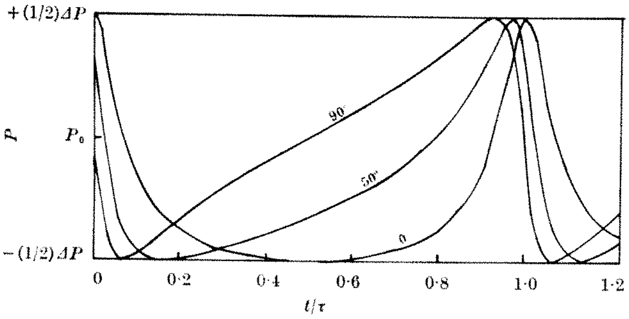

Fig. 1. Variation in the observed period of a pulsar due to its orbital motion relative to the centre of mass of the planet–pulsar system. The cases shown are for values of ω of 0°, 50°, and 90° and $e=0·6$.

For mass in $M_\odot$ and τ in years the maximum variation in the period of a pulsar due to orbital motion is

$$\frac{\Delta P_{\max}}{P_0} = \left[\frac{1·99\times 10^{-4}\, m \sin i}{(1-e^2)^{1/2}\tau^{1/3}\,(M+m)^{2/3}}\right] \qquad (9)$$

Fig. 1 shows, for illustration, the time dependence of P for $e=0·6$ and various values of ω. For large ω and e the minimum time, $\Delta t_{\min}$, required to go through the maximum period range, $\Delta P_{\max}$, is much less than 0·5 τ. In Table 1 I have tabulated $(\Delta t_{\min}/\tau)$ as a function of e and ω. If $(\Delta t_{\min}/\tau)$ is small the pulsar will be observed to undergo an apparently abrupt increase or decrease in period depending on the orientation of the planetary orbit if it is not observed with sufficiently high time resolution. Both radio[8] and optical[9] observations have recorded a decrease in the period of NP 0532 of $(\Delta P/P_0)=2·3\times 10^{-9}$ within the fifteen day interval between October 8 and October 23, 1969. Because this is about 0·16 of the orbital period of the planet, it could be explained by the planet being in an orbit having e as low as 0·55 if $\omega=90°$ or $e=0·7$ if $\omega=45°$, the average ω for randomly oriented orbits. From equation (9) we find that the minimum m required to explain the observed $(\Delta P/P_0)$ is 1·3 $M_\oplus$ if $e=0·8$ and $\tau=0·25$ yr, which is very close to the m required to explain the quasi-sinusoidal variation in the period of the pulsar. If the abrupt drop in period was caused by the planetary companion a similar drop can be expected towards the end of January due to the three month period of the planet.

It is desirable to look for longer-period semi-sinusoidal variations in NP 0532 produced by planets in more distant orbits. A planet with a mass equal to that of Jupiter in an orbit with $e=0·8$, $\omega=70°$ and located 5 AU from the pulsar could produce a period change $(\Delta P_{\max}/P_0)=1·5\times 10^{-7}$ within an eight month interval. In the theory of planet formation which I suggested[4] it is doubtful whether Jovian-type planets can form around main sequence stars that are very much more luminous than the Sun as presumably was the case for NP 0532; on the other hand, it would be surprising if no more terrestrial-type planets are found in the system.

Even with a planet of Jovian mass it is difficult to account for the period change $\Delta P/P_0=1·5\times 10^{-6}$ observed within a seven-day interval in PSR 0833–45 (refs. 10 and 11). A suggested[12] decrease in the moment of inertia following a stellar quake may be a reasonable explanation for a change of this magnitude. More observations with finer time resolutions are needed to help interpret these sudden changes in period.

Plasma Turbulence as a Mechanism of Pulsar Radiation

RADIO signals from pulsars are characterized by (1) high intensity, with brightness temperatures of the order of 10^{21} K (ref. 1); (2) pronounced (mostly linear) polarizations with, in the case of PSR 0833 (ref. 2), a monotonic sweep of the polarization angle during each pulse; (3) narrow pulse widths (Δt) compared with the repetition period (P); and (4) optical, X-ray and radio pulse widths which are virtually the same[3]. This report is about a pulsar model in which anisotropic plasma turbulence, produced by the onset of a two-stream instability near the light cylinder of a rotating magnetic star, is the chief radiation mechanism. The model offers a quantitative, self-consistent account of features (1)–(3) for quite different pulsars, and a qualitative explanation of feature (4).

We consider a plasma with electron density n near the light cylinder corotating with the magnetic star. The magnetic lines of force passing through the plasma penetrate the light cylinder and may reach the supernova shell or interstellar space[4]. We also assume a (relativistic) electron beam with density n_b and velocity $\mathbf{v}$ along the magnetic lines of force, so that this is a typical case of a two-stream instability in the plasma. The plasma will thus be strongly turbulent, with the static form factor $S(\mathbf{k})$ (ref. 5) of the density fluctuations in the wave-vector space enormously enhanced over thermal levels.

Because of the anisotropy caused by the magnetic field $\mathbf{B}$ and the streaming electrons $(\mathbf{v}\|\mathbf{B})$, we expect enhanced electromagnetic radiation associated with the plasma turbulence. The power $\mathrm{d}^2\mathcal{P}/\mathrm{d}o\,\mathrm{d}\omega$ of such radiation in the frequency interval $\mathrm{d}\omega$ emitted through a unit normal area into a solid angle do in the direction of **k** is (ref. 6 and my unpublished work with Starr)

$$\frac{d^2\mathcal{P}}{do d\omega} = \frac{ne^2}{2\pi^2 c^2}\,\omega^3 \int_0^\infty dk\; \frac{|\varepsilon_1|^2 + |\varepsilon_2|^2}{k^3}\, S(\mathbf{k})\delta(\omega - \mathbf{k}\cdot\mathbf{v}) \qquad (1)$$

where

$$\varepsilon_1 = \frac{\omega_p{}^2 \Omega^2}{\omega^2(\Omega^2 - \omega^2)} \sin\theta\cos\theta \qquad (2)$$

$$\varepsilon_2 = i\,\frac{\omega_p{}^2 \Omega}{\omega(\Omega^2 - \omega^2)} \sin\theta \qquad (3)$$

$\omega_p = (4\pi n e^2/m)^{1/2}$, $\Omega = eB/mc$, and θ is the angle between **k** and **B**. In equations (2) and (3) we have neglected the contribution of the streaming electrons by assuming $n \gg n_b$.

The detailed structure of the spectral function $S(\mathbf{k})$ should be determined from the solution of a non-linear self-consistent integral equation[7]. Here it suffices to note that the spectrum is broad enough to cover the observed range of radio frequencies and that it takes on a maximum value at about $k_m = \omega_p/v$ when **k** is parallel to **B**. The properties of pulsar radiation can now be correlated with equation (1).

(1) The beam-plasma system can inherently sustain unstable collective modes down to $k = 0$. The level of turbulence in such a system is limited only by particle collisions or by the effect of the finite system dimension. For plasmas surrounding rotating magnetic stars, we expect collisional effects to play the chief part. The average level of turbulence $\langle S \rangle$ may be estimated to be (ref. 7 and my unpublished work)

$$\langle S \rangle \simeq n l^2 k_m / 2\pi K^2 \qquad (4)$$

where l is the mean free path and K is a maximum perpendicular wave number for the collective modes to be relatively undamped excitations and n/K^2 measures a line density of the electrons involved in the two-stream instability. When $\Omega^2 \gg \omega_p{}^2$, $K^2 \simeq (m\Omega^2/\varkappa T)$; and when $\Omega^2 \ll \omega_p{}^2$, $K^2 \simeq (m\omega_p{}^2/\varkappa T)$, where $\varkappa$ is the Boltzmann constant and T is the electron temperature. According to equation (4) (and equation (6) later) there should be quite different turbulent behaviour for "fast" as against "slow" pulsars, because a fast pulsar has a large B at the light cylinder. B differs so much that it is reasonable to assume $\Omega^2 \gg \omega_p{}^2$ for fast pulsars such as NP 0532 and PSR 0833 and $\Omega^2 \ll \omega_p{}^2$ for slow pulsars such as CP 0328 and CP 1919, an assumption which will be shown to be self-consistent.

(2) From equations (2) and (3), we note that

$$|\varepsilon_1/\varepsilon_2| = |\Omega/\omega| \cos\theta \qquad (5)$$

Thus, when Ω is much greater than the relevant frequencies of the radio emission, we have $|\varepsilon_1/\varepsilon_2| \gg 1$ and the radiation is linearly polarized in the direction perpendicular to **k** on the plane made by **k** and **B**. When $\Omega \ll \omega$, $|\varepsilon_1/\varepsilon_2| \ll 1$ and the radiation is linearly polarized in the direction perpendicular to the plane of **k** and **B**. The **k** direction is fixed in the line of sight—the **B**–**k** plane (that is, the **v**–**k** plane) rotates around this line as the star rotates. Thus the sweep of the position-angle is explained. We also note in equation (5) that the degree of linear polarization depends on the frequency of observation. In the case of PSR 0833 (where $\Omega \gg \omega$), lower frequency radiation should be more linearly polarized[2].

(3) Radiation from the anisotropic plasma turbulence due to the two-stream instability has exactly the property of emission in a pencil or fan beam which seems necessary to explain the pulsations. Turbulence is strongest when **k** is parallel to **B**; it decreases sharply as **k** acquires a component perpendicular to **B**, either because of the finite Larmor-radius effects (when $\Omega^2 \gg \omega_p{}^2$) or because of Landau damping (when $\Omega^2 \ll \omega_p{}^2$). The angle θ_m of the "cone" within which the wave vectors of the turbulent fluctuations are confined may then be estimated from such consideration as

$$\theta_m \simeq \begin{cases} \tan^{-1}[\Omega(mc^2/E_p)(m/\varkappa T)^{\frac{1}{2}}(v/\omega_p)] & (\text{for } \Omega^2 \gg \omega_p{}^2) \\ \tan^{-1}[\omega_b(mc^2/E_p)^{\frac{1}{2}}(m/\varkappa T)^{\frac{1}{2}}(v/\omega_p)] & (\text{for } \Omega^2 \ll \omega_p{}^2) \end{cases} \qquad (6)$$

where $\omega_b = (4\pi n_b e^2/m)^{\frac{1}{2}}$, and $E_p = c(p^2 + m^2c^2)^{\frac{1}{2}}$ is the energy of a streaming electron with the momentum p. The ratio $\Delta t/P$ must then be equal to or somewhat smaller than θ_m/π.

Table 1. OBSERVED OR ESTIMATED QUANTITIES

	Period P(G)	Width Δt(ms)	Radio power $E[10^{-26}$ J m^{-2} Hz$^{-1}]$	Distance D[kpc]	Electron density n[cm^{-3}]	Electron temperature T[K]

CP 1919	2·7	$7{\cdot}1 \times 10^{11}$	3×10^{-1}	—	$1{\cdot}7 \times 10^{-7}$

Tables 1 and 2 summarize the comparison with observations. In Table 1, P, Δt and E are from raw data[1], and in column 4 we use the distance estimates from ref. 8. Each value of E may then be converted into the radiation intensity at the source by assuming that the emitting region has radius, $L = cP/2\pi$. The electron densities (column 5) are chosen so that the plasma frequencies fall within the ranges of the observed radio frequencies and the values reflect our effort to take account of the pulsar radio spectrum[1]. The electron temperatures (column 6) are the estimated surface temperatures ($\sim 10^6$ K) of neutron stars, and the smaller values for the slow pulsars are from the inequality $n\varkappa T/(B^2/8\pi) < 1$, a condition for a magnetically controlled plasma. These choices are physically consistent with the idea of plasma cooling as L increases for a slow pulsar. The Coulomb mean-free-paths are then computed.

The numerical values are substituted into the expressions for radiation intensity and pulse width, thus determining the strength of the magnetic field in the emitting region (column 1 of Table 2). Self-consistency of our model would then demand that those magnetic fields represent the fields appropriate to the vicinity of the light cylinder. To check this, we compute $B_0 = B(L/10^6)^3$ in column 2. This quantity should give an estimate of the strength of the surface magnetic field, assuming a dipole field and a stellar radius of about 10 km. The calculated surface fields B_0 agree almost within an order of magnitude and agree with the estimate[3] of 10^{12} G, despite the wide variation of B values. Consideration of other geometrical factors could increase the computed values of B_0 further and hence improve the comparison.

The ratio $\beta = n\varkappa T/(B^2/8\pi)$ is computed in column 3 and the plasmas are well under the control of the magnetic fields.

Our calculations also give the momentum of a beam electron in the cases of the fast pulsars (column 4) or the ratio $(n_b/n)(mc/p)$ for the slow pulsars (column 5). This indicates the existence of a beam of relativistic electrons with energy $\sim 10^{11}$ eV and $(n_b/n) \sim 10^{-2}$.

Relativistic electrons passing through a turbulent plasma are scattered by the turbulent fluctuations of the electric field and acquire velocities perpendicular to the magnetic field. The directions of the turbulent electric fields are confined within the cone of equation (6) so the pitch angles of the resulting spiral motion of the scattered electrons should also be limited within the same cone. Each relativistic electron, being accelerated by the magnetic field and the turbulent electric fields, then emits optical and X-ray radiation along its own direction of motion (the angular spread $\Delta\theta \sim 10^{-5}$ for 10^{11} eV). These must therefore have the same pulse width as the radio emission.

The characteristic difference between the fast and slow pulsars and the frequency dependence of the degrees of linear polarizations will provide tests of our model.

I thank Professor D. Pines for discussions and comments, and the Aspen Center for Physics for hospitality during the course of this work. The research was supported in part by the US Army Research Office (Durham).

Angular Size of the High Energy X-ray Source in the Crab Nebula

THIS article reports new data on the spatial structure of the source of 25 to 100 keV X-rays in the Crab nebula, obtained with a balloon-borne X-ray modulation collimator. The angular diameter of the Crab for energies of 1·2 to 12 keV has been measured previously in two rocket experiments by lunar occultation[1] and by modulation collimator[2]. Both measurements showed that the low energy X-rays come from an extended region one to two arc minutes in diameter centred on the visible nebula. Since then the radio[3] and optical[4] pulsar NP 0532 has been identified with a central star in the nebula[5].

NP 0532 emits radio and optical pulses with a distinctive double peak at a frequency of approximately 30 cycles s^{-1}. Similar pulsations in the X-ray flux[6] comprising 9 per cent of the 1·5 to 10 keV X-ray output of the Crab[7] have been detected which almost certainly come from the immediate vicinity of NP 0532. This suggests a two-component model for the Crab at low X-ray energies, consisting of a point source associated with the pulsar, surrounded by a nebula about two arc minutes across. The pulsar may also account for part of the non-pulsed flux. Present evidence cannot exclude a cluster of non-pulsed point sources for the nebular component of the source[8].

At higher photon energies[9] the pulsed X-ray component comprises 15 ± 5 per cent of the total 25 to 100 keV flux[10], but there have been no measurements of the angular diameter of the source at energies above 12 keV.

The experiment described here indicates that the source of 25 to 100 keV X-rays (including the pulsed component) in the Crab nebula has an effective angular diameter of at least 1·1 arc minutes and that the contribution of the point source to the total flux is no more than 40 per cent in that energy range. This contradicts the suggestion[11] that the Crab is actually a point source of X-rays and that its nebular appearance in the 1·2 to 12 keV range is caused by scattering of the X-rays from interstellar grains. If this were true, the apparent diameter of the source in the 25 to 100 keV range would be less than 0·25 arc minutes because of the rapid decrease with photon energy of the scattering cross-section of dust grains[12].

The X-ray telescope carried a pair of identical grid-modulation collimators with resolution angles of two arc minutes. The collimators, mounted together to a single frame, were supported by gimbals and stabilized in inertial space by rate integrating gyros programmed to rotate the collimators at a uniform angular rate of 16° h^{-1}, so that X-rays passing through the collimators were intensity modulated at a frequency of 8 cycles per minute. The depth of modulation depends on the angular divergence of the beam, being 100 per cent for a point source at infinity and decreasing to zero as the angular diameter of the source approaches the collimator resolution angle of two arc minutes. Behind each collimator the beam intensity was measured with a 280 cm^2, NaI(Tl) scintillation detector with active and passive shielding. The energy acceptance window, set by pulse height discriminators, was 25 to 100 keV.

The instrument was launched from the NCAR balloon base at Palestine, Texas, on May 10, 1969, and floated at 130,000 feet from 1126 to 1852 CDT within a few miles of latitude 31·1° N, longitude 93·0° W. The modulation collimators scanned the Crab ten times, averaging 10 min each. The average source intensity measured by detector A was 0·085 counts cm^{-2} s^{-1} which is consistent with results reported for a similar instrument[13]. Because of degraded sensitivity detector B recorded only half this intensity. Averages of the count rate over 1 s were telemetered to the ground and recorded on magnetic tape.

The total X-ray intensity measured by a detector was assumed to be the sum of (*a*) background radiation, (*b*) unmodulated source flux, and (*c*) modulated source flux. Components (*a*) and (*c*) were constant or slowly varying in time while (*c*) varied periodically at a frequency of about 8 cycles per minute with unknown amplitude and phase. The exact frequency depended on the pointing direction and was known from telemetered engineering data. Because of the high background intensity, component (*c*) was not directly observable in the data record. To infer the angular diameter of the source it is necessary to measure the magnitude of component (*c*) relative to (*b*). The discrete Fourier transform of the counting rate in each detector during each scan of the Crab was presented as a normalized power density spectrum. The normalized power density spectrum is the squared magnitude of the Fourier spectrum divided by the total X-ray count accumulated during the scan interval.

Each frequency component, Q_i, of the normalized power density spectrum is a random variable. At frequencies other than the modulation frequency, Q_i has an exponential probability distribution, $P(Q_i) = \exp(-Q_i)$. At the modulation frequency its probability function is

$$P(Q_j) = I_0(2\sqrt{Q_j V}) \exp(-Q_j - V) \qquad (1)$$

where I_0 is the zeroth order modified Bessels function of the first kind and V is a parameter describing the normalized amplitude of the modulated component of source flux. For a one-dimensional source model of uniform brightness and angular width, α, V is given by

$$V = \frac{(0{\cdot}81S)^2 T}{(B+S)} \left(\frac{\sin \pi\alpha/\alpha_0}{\pi\alpha/\alpha_0}\right)^2 \qquad (2)$$

where α_0 is the collimator resolution angle (2 arc minutes), T is the scan duration in seconds, B is the background intensity and S is the total source intensity averaged over T.

It can be shown that the expected value of Q_j is $(1+V)$ at the modulation frequency while at all other frequencies its expected value and standard deviation are both unity. The observed amplitude of Q_j is therefore expressed directly in standard deviations of the exponential distribution. A peak at the modulation frequency of amplitude $Q_j=1+(0{\cdot}81S)^2\ T/(B+S)$ represents a point source, while $Q_j \approx 1$ implies that the source diameter is equal to or greater than the collimator resolution angle. Because the scan rates and resolution angles of both collimators are identical, a modulated component of source flux would produce coincident peaks in the power density spectra of both detectors, while peaks due to random fluctuations would show no correlation between detectors. This increases the statistical significance of observed peaks.

Table 1. RESULTS OF DETECTOR A

(*a*) Scan duration (s)	(*b*) Source intensity (counts s^{-1})	(*c*) Expected peak for point source (standard deviation)	(*d*) Observed peak (s. d.)	(*e*) Lower limit on diameter (arc minutes)	(*f*) Upper limit on point source contribution (per cent)
540	3·3 ± 0·5	20 ± 7	5	0·4	90
720	3·2 ± 0·5	25 ± 8	1	1·1	41
540	4·7 ± 0·5	39 ± 8	3	1·1	60

Table 1 summarizes the three scans of detector A having the best source-to-background intensity ratios. The measured source intensity (column *b*) is the total intensity averaged over the scan interval less the background intensity, which was periodically monitored throughout the flight. The expected peak for a point source (column *c*) was calculated from equation (2) with $\alpha = 0$. The observed peak (column *d*) is the largest peak, within the uncertainty range of the modulation frequency, which coincides with a peak of any amplitude in the B detector spectrum (within the half-amplitude width of the peak). In every case the observed peaks are much smaller than expected for a point source, implying that the diameter of the X-ray source is about the same as (or larger than) the collimator resolution angle.

To interpret the results quantitatively, an upper limit was first placed on the strength of the modulated component by finding the smallest V which, with probability 0·99, would have produced a peak larger than that observed. This value of V was then interpreted in two ways. First it was used in equation (2), with the value of S in column *b* of Table 1, to find the width of an extended, uniformly bright, one dimensional source. The result is listed in column *e* of Table 1 as the lower limit on source diameter. The collimator transmission bands, which were horizontal, intersected the lines of declination at angles of +35 and −42 degrees for the second and third scans, so that the 1·1 arc minute limit is valid for two nearly orthogonal axes. For an alternate interpretation, the upper limit on V was used to place an upper limit on the possible point source contribution (including pulsed flux) to the total intensity of a two-component source model with the nebular component being two arc minutes in diameter. This is listed in column *f* as a percentage of the total 25 to 100 keV Crab flux. Point source contributions of more than about 40 per cent are therefore ruled out. This upper limit is consistent with previous observations[10] of the pulsed component of X-radiation.

No significant coincident peaks were found in any of the other scans, but in these other data the statistical significance is lower because of the lower counting rates.

All instrumental effects which could have smeared the modulated signal were systematically investigated before and after the flight and were found to be negligible. Tests during the flight indicated that all systems were operating properly, and I am confident that the instrument was not responsible for any significant attenuation of the modulated component and that the conclusions drawn from these data are valid. It is important, however, that these results be verified independently because they are relevant to our understanding of the mechanisms by which the pulsar could give rise to X-ray emission from the Crab.

Characteristic Variation of Sco X-1

Rao, Rao and Jayanthi[1] have published results of their autocorrelation analysis of the optical photometry of Sco *X*-1, which they claim show a clear periodicity of about 3·0 h. They treated individual nights separately, finding respective periods of 4·43, 3·07, 2·04, 3·25, 3·00 and 0·96 h on six of the longer runs available. It seems that one should be able to say little about periodicities of the order of three hours when continuous coverage of at most eight hours is at hand, when the correlation coefficients are not very significant, and when the periods for only three of the six nights are close to three hours. Regardless, however, of opinions as to whether any significance should be attached to their analysis, we wish to point out that a much more profitable approach to studying the photometry of Sco *X*-1 is afforded by a simple inspection of the time variation. Suppose, for the moment, that the brightness changes of Sco *X*-1 were nearly random but that at irregular intervals a characteristic variation were

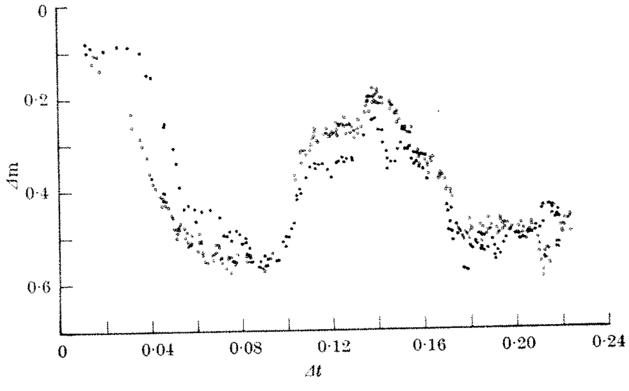

Fig. 1. Photometry of Sco *X*-1 on two nights (○, April 18, 1967; ●, May 9, 1968). The time scale is in days.

to appear for, say, a few hours. Such a variation would not be periodic and should not lead to significant periodic terms in a power spectral analysis of a long continuous sample, but it could be the signature of a physical process which, although happening at unpredictable times, behaves in a characteristic way each time that it does occur. Furthermore, in a restricted data sample, such as we have at our disposal from the published photometry, such a characteristic variation could mimic a weak periodicity without, of course, having any obligation to continue being periodic during the gaps in the observations.

To look for such a pattern, we have made graphs, on a common scale, of most of the available observations. Differences in scale factors used in graphs by different observers may be responsible for some of the obviously interesting features having gone unnoticed. In Fig. 1 we have plotted observations separated by more than a year[2,3] with the time and magnitude zero points adjusted so as to bring them into register. The adjustment in the magnitude scale is only about 0·1 magnitudes. During the first half of each run there is a feature which can be seen in whole or in part on a surprising number of nights. It looks like a distorted total eclipse, showing, in fact, all four contacts as points of sharply changing slope. We do not believe that this can actually be an eclipse because simple computations show that its duration, relative to the necessary hypothetical period, far exceeds the maximum possible duration for even a contact binary. In Fig. 2 we show photometry from a third night[2]. We have not overlaid this with the previous two graphs because visual disentangling of the three nights would begin to be difficult. The "eclipse" here is wider than those of Fig. 1, but its first stages can be overlaid very well with those of Fig. 1, as can its last stages. The general phenomenon seems to have been the same on this night, with a slight time lag between "second contact" and "third contact". Following the "eclipse" a short rise is followed by a small hill of about 0·1 magnitudes on each of the three nights. The behaviour subsequent to the hill is again similar on the three nights. Of course, as the graphs match so well, it is not only the amplitudes of these features which correspond, but also the time intervals between them. Parts of these features are seen on a number of other nights and, although one must be on guard against seeing regularities in random variations, we feel that we have been cautious and that the repetitions are unquestionably real.

We believe that we have compared all photometric observations which are useful for a study of this kind (about ten to fifteen nights, depending on the criterion for shortest useful run). We have not referenced those for which the length of the runs was too brief to show patterns on a time scale approaching six hours, but we have specifically looked at the paper by Sandage, Westphal and Kristian[4] in which some of the runs are long enough to be marginally useful. In their paper there is one interval of a few hours which follows the characteristic variation, but our main evidence is drawn from refs. 2 and 3.

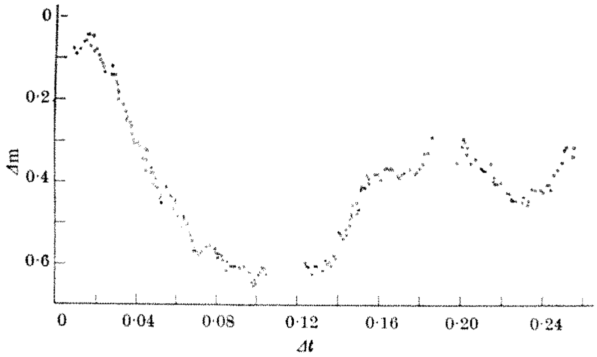

Fig. 2. Photometry of Sco X-1 on a third night (April 17, 1967). The time scale is in days.

We do not at present wish to attribute this behaviour to a particular physical process, but we find it interesting that it is not inconsistent with the mechanism recently suggested by Sofia[5] in which ionized interstellar matter is guided down magnetic field lines to be accreted onto a neutron star. That is, as the material is constrained by the field lines to follow a particular flow pattern, we may expect a consistent sequence of events whenever accretion of an interstellar cloudlet occurs.

Water Vapour in Sunspots

Features attributable to the water vapour molecule have been detected in the spectra of several late type stars during the previous decade, particularly by Woolf *et al.*[1], who observed in the 1·13 μm, 1·4 μm, 1·9 μm and 2·7 μm absorption bands using a balloon-borne spectrometer. Spinrad and Newburn[2], Wing *et al.*[3] and Spinrad *et al.*[4] have obtained coudé and Cassegrain spectra in the neighbourhood of 0·9 μm and demonstrated the great strengthening of the water vapour absorption in this region in the spectra of many stars, more especially Mira. Sinton[5] has worked in the region 1·9 μm to 2·5 μm using a ground-based interferometer and has shown that there is water vapour absorption in the stars R Leo and χ Cyg, and McCammon *et al.*[6] have also obtained spectra in this region at Mt Wilson and Palomar. Although at the low temperatures of these stars a detectable concentration of water vapour would be expected, such measurements are of interest because they provide evidence for particular atmospheric models. The purpose of this note is to present evidence for the existence of water vapour in sunspots.

In principle, any HOH absorption band may be used for detection. Because spectra of sunspots may be obtained most easily in the visible region, however, observations of HOH lines at these wavelengths have been attempted by Wöhl[7] and by E. A. M. and D. E. B.[8]. Unfortunately the complex nature of the sunspot spectrum inhibits reliable identification here, chiefly because it is almost impossible to distinguish between enhanced telluric HOH lines and weak sunspot lines of unknown origin. In Fig. 1 we show an improved spectrum of a sunspot in the region of 5880 Å obtained with the rapid scanning photoelectric spectrometer at the Gornergrat Observatory of Oxford University[9], in Switzerland, together with the corresponding spectrum of the adjacent photosphere observed immediately afterwards as a comparison. The water vapour lines in the photospheric spectrum are due wholly to absorption in the Earth's atmosphere; their positions are indicated by arrows, and their wavelengths and identifications are taken from the second Revised Rowland Table of Moore *et al.*[10]. The dryness of the atmosphere at the Gornergrat can be judged from the shallowness of these telluric lines. This sunspot spectrum was obtained on November 18, 1969, and is of the sunspot having Rome No. 5607 which had a diameter of about 20 arc sec. The width of the spectrometer slit corresponded to $\lambda/\Delta\lambda = 1{\cdot}96 \times 10^5$. Inspection of the spectrum shows that there is indeed a small but apparently significant increase in the equivalent width of the water vapour lines, but precise measurement is uncertain because of the complexity of the sunspot spectrum. A discussion of a slightly inferior spectrum of this region has been given by E. A. M. and D. E. B.[8].

In order to increase the reliability of interpretation we have also obtained a spectrum of a sunspot in the region of 9300 Å where both photospheric and sunspot spectra are comparatively simple. For this purpose we used the Gornergrat spectrometer with an RCA infrared photomultiplier having an S1 cathode cooled with dry ice. The quantum efficiency of this type of cathode is small so that the signal is relatively noisy, but the arrangement of the Gornergrat spectrometer allows integration of the signal to be effected for an almost unlimited time with a consequent improvement in the signal-to-noise ratio. The spectrometer incorporated a Bausch and Lomb echelle grating of 100 lines mm^{-1} used with a slit width $\Delta\lambda$ corresponding to $\lambda/\Delta\lambda = 2{\cdot}0 \times 10^5$ in the sixth order, and on this occasion an integration time of 2 s per point was used. The spectrum was obtained on January 29, 1970, and is of the sunspot having Rome No. 5674 with umbral size 20 s × 10 s, on the west side of the solar disk at cos $\theta = 0{\cdot}68$. The entrance aperture of the spectrometer was 7 s × 1 s.

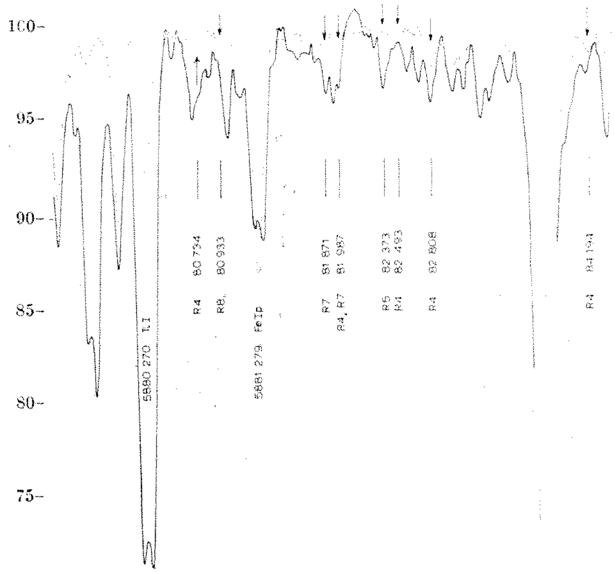

Fig. 1. Sunspot (———) and photospheric (. . .) spectra in the region of 5880 Å.

Any observed sunspot spectrum is contaminated with light scattered into the image of the spot from surrounding photospheric regions, either by the telescope or by the Earth's atmosphere. We have corrected our observed spectrum for the presence of 50 per cent photospheric light. This value was obtained by comparing the observed ratio of umbral and photospheric continuum intensities with model atmosphere calculations for a spot temperature distribution given by $\Delta\theta = 0{\cdot}3$ (where $\Delta\theta$ is the difference in θ between sunspot and photosphere, and $\theta = 5040/T$). The proportion of scattered light is high for this wavelength region, but the observations were obtained under very poor seeing conditions. The corrected spectrum, termed the "reduced" spectrum, is shown in Fig. 2, which also shows a photospheric spectrum obtained immediately afterwards using an adjacent region of the solar disk. The absorption features in this spectrum are labelled by arrows against wavelengths taken from the catalogue of Babcock and Moore[11]. These features are identified in this catalogue only as of "atmospheric origin", but a comparison with an HOH flame spectrum obtained by Spinrad and Newburn[2] at a resolving power of about 46,000 shows that the majority at least are rotational lines in the 201 vibrational band of HOH, which has a band head at 9278 Å and was first identified by Gaydon[12]. In the upper part of Fig. 3 we show smoothed versions of both the photospheric and the reduced sunspot spectra.

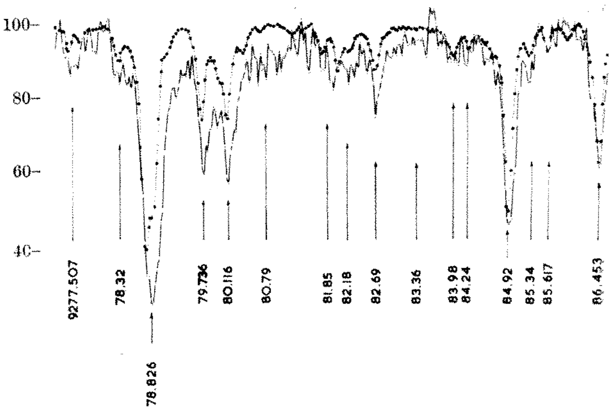

Fig. 2. Sunspot (— · —) and photospheric (● · · · ●) spectra in the region of 9300 Å.

In order to obtain the true sunspot spectrum that would be observed outside the Earth's atmosphere, termed here the "intrinsic" sunspot spectrum, we must also correct for absorption by water vapour in the Earth's atmosphere. In doing this we assume that the photospheric spectrum in this region simply delineates the telluric absorption spectrum. The result is given by the lower curve of Fig. 3. This spectrum gives the strength of the purely umbral HOH in as far as lines arising from other molecular or atomic species are absent. This analysis is complex and based on uncertain assumptions. For example, any scattering in the upper part of the Earth's atmosphere will tend to contaminate the spot spectrum with an intrinsic photospheric spectrum, and not an observed photospheric spectrum, which contains telluric lines. Further, we are obliged to assume, as is likely, that all of the photospheric absorption features are of telluric origin and treat them accordingly. These are comparatively minor matters which do not greatly affect our conclusion, however.

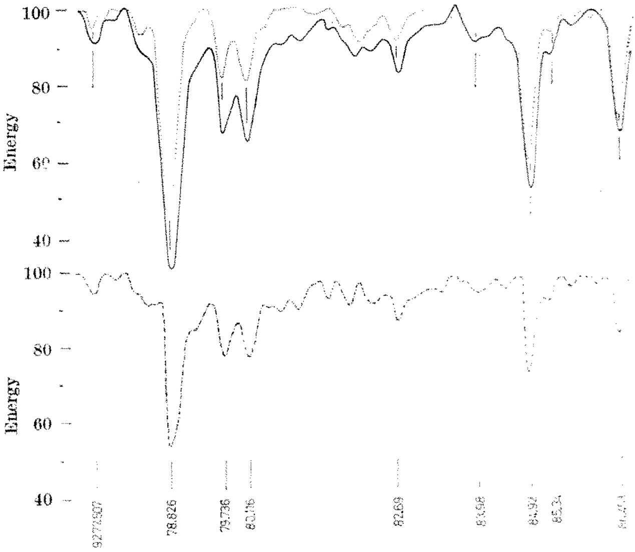

Fig. 3. Smoothed spectra of sunspot (———) and photosphere (. . .) in the region of 9300 Å, corresponding to Fig. 2. The lower spectrum (— · —) is of the spot alone as it would appear outside the Earth's atmosphere, allowance having been made for telluric water vapour lines.

Table 1. EQUIVALENT WIDTHS OF HOH LINES

Wavelength	Equivalent width (W) W_{telluric}	W_{spot}	$W_{\text{spot}}/W_{\text{telluric}}$
9278·826	189 mÅ	158 mÅ	0·84
9279·736	44	72	1·64
9280·116	59	76	1·29
9282·69	23	29	1·26
9283·98	15	12	0·83
9284·92	106	48	0·45
9286·453	68	25	0·37

It is evident from a comparison of the photospheric and reduced sunspot spectra, and from inspection of the intrinsic spot spectrum, that all of the principal HOH lines are enhanced in the spot spectrum. These lines are indicated in the upper spectra by short bars. Furthermore, the enhancement is not the same for all lines, those nearer the band head being the more enhanced. This is shown by the data of Table 1, which gives the equivalent widths of HOH lines in the photospheric (that is, telluric) and intrinsic sunspot spectra, together with the ratios of their equivalent widths in the two spectra. A detailed analysis of this water vapour band does not exist, so that an accurate assignment of J-values cannot be made. The rotational lines nearest the band head will be of high J-number, however, and we thus infer from the data of Table 1 that the J-value corresponding to maximum intensity is higher in the sunspot spectrum than in the telluric spectrum. This provides additional evidence that the extra absorption in the HOH lines originates in the spot, the shift in the position of maximum occurring because the spot has a higher temperature than the Earth's atmosphere. Although this effect is qualitatively apparent, a quantitative interpretation is not straightforward because certainly the telluric lines, and probably the stronger HOH lines in the umbral spectrum also, are saturated, or nearly so.

Some support for this interpretation of the sunspot spectrum is provided by the observed redshift of about 70 mÅ between telluric and intrinsic sunspot HOH lines. This shift is higher than that of 47 mÅ which would result from the Doppler effect arising from the rotation of the Sun, but we would ascribe such a difference to uncertainties in the reduction procedure. An increase in line width would also be expected in the intrinsic sunspot HOH lines compared with the telluric lines. The resolution of the smoothed spectrum is unfortunately insufficient to show this increase with certainty.

Another scan of the same spectral region was made on January 28, 1970, when the water vapour content of the Earth's atmosphere was considerably higher than on January 29. On this occasion the line at 9278·826 had a depth of 86 per cent in the photospheric spectrum. Even in these conditions the observed sunspot lines are clearly deeper than the photospheric lines. But although a similar analysis of this spectrum gave an intrinsic spectrum that showed HOH lines of depths similar to those in Fig. 3, the spectrum, as might have been expected, was much more noisy. This experience confirms that an extremely dry atmosphere is necessary for the detection of the amount of water vapour that we have observed in this sunspot.

The Gornergrat station of the University of Oxford is operated as part of the Hochalpine Forschungsstation Jungfraujoch. We thank the director of this organization, Dr H. Debrunner, for help with the administrative problems of the station, and the Science Research Council for a grant for erection and operation of the station.

Determination of the Radial Velocity of a Relativistic Star

WE shall calculate the value of the radial velocity of a relativistic atom from the shift of the spectral lines by taking the transverse velocity into account. The special theory of relativity will be used.

Let us consider a system of coordinates S with rectangular axes $Oxyz$ and an atom (for example, an atom of a moving star) moving in S with a uniform velocity $\mathbf{u}$. When this atom reaches the point with coordinates $(x,0,0)$ in S $(x>0)$ it emits a photon which moves in S along the Ox axis towards the origin O where an observer is at rest. Let ν and ν_0 be the frequencies of the photon in S and in a system of coordinates in which the atom is at rest. These frequencies are connected by the relativistic Doppler formula. Following Moller[1] we have

$$\nu_0 = \nu(1+u_x/c)(1-u^2/c^2)^{-1/2} \qquad (1)$$

where c is the velocity of light and u_x the component of $\mathbf{u}$ on the Ox axis. Let $\mathbf{e}$ be the unit vector of the Ox axis (the direction of the observation), $u_x\mathbf{e}$ is the radial velocity and $\mathbf{v}=\mathbf{u}-u_x\mathbf{e}$ is the transverse velocity. Equation (1) is equivalent to

$$(u_x/c)^2(1+a^2)+2(\mu_x/c)+1-a^2+a^2(v/c)^2=0 \qquad (2)$$

where $a=\nu_0/\nu$. The two roots u_{x_i} $(i=1,2)$ of equation (2) are

$$\frac{u_{x_i}}{c} = -\frac{1}{1+a^2} - (-1)^i\,\frac{a}{1+a^2}\,[a^2-(1+a^2)(v/c)^2]^{1/2}$$

In order to obtain real numbers, the magnitude v $(0\leq v<c)$ of the transverse velocity must satisfy the relation $v\leq v_{\text{M}}$, where $v_{\text{M}}=c(1+1/a^2)^{-1/2}$. Furthermore, these roots will be satisfactory if we have $-c<u_{x_i}<c$ $(i=1,2)$. Let us remark that for a determined value of a, these roots are functions of the magnitude of the transverse velocity.

A graphical construction of these roots is represented in Fig. 1. Equation (2) between the variables v/c and u_x/c is the equation of an ellipse. Let us consider the rectangular axes associated with these variables (Fig. 1). The centre of this ellipse is at the point D $(0,-1/1+a^2)$. The values of the semi-axes DA and DB are DA$=v_{\text{M}}/c$ and DB$=(v_{\text{M}}/c)^2$. The point with coordinates $(0,-1)$ is common to all the ellipses. The values u_{x1}/c and u_{x2}/c of the roots are then respectively the second coordinates (on the u_x/c axis) of the two points M_1 and M_2 of the corresponding ellipse, the first coordinate of which is v/c $(0\leq v\leq v_{\text{M}})$. The corresponding values u_1 and u_2 of the magnitude of the velocity $\mathbf{u}$ are represented by the lengths $\text{OM}_1=u_1/c$ and $\text{OM}_2=u_2/c$. When $v=0$, only the root $u_x/c=(a^2-1)/(a^2+1)$, represented by the point B, is satisfactory; this is the solution obtained when the transverse velocity is neglected.

Two cases must be distinguished according as $a\leq 1$ or $a>1$. When $a\leq 1$, for each value of the transverse velocity such as $0<v\leq v_{\text{M}}$ the two corresponding values u_{x1} and u_{x2} of the radial velocity are negative. Thus for

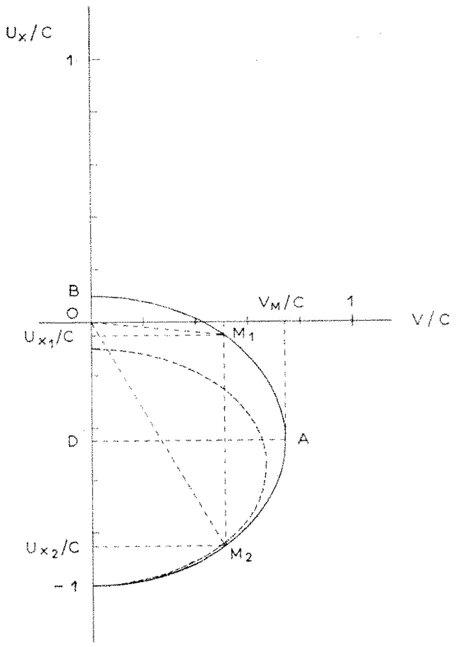

Fig. 1. Graphical determination of the radial velocity. The ellipse (———) is drawn for $a=1{\cdot}1$ (case $a>1$ in the text). For each value of v/c ($0<v\leqslant v_M$) the coordinates on the u_x/c axis of the two corresponding points M_1 and M_2 of the ellipse are the values u_{x_1}/c and u_{x_2}/c of the radial velocity. The ellipse (- - -) is drawn for $a=0{\cdot}9$ (case $a\leqslant 1$ in the text).

these values of a we may conclude that the atom moves nearer to the observer.

When $a>1$, if the value of the transverse velocity satisfies the conditions $0<v<v_0$ where $v_0=c(1-1/a^2)^{1/2}$, then the root u_{x1} is positive and the root u_{x2} is negative. Thus, if we know only the value of the ratio of the frequencies, it is impossible to state that the atom moves nearer to or away from the observer. If $v=v_0$, then $u_{x1}=0$ and u_{x2} is negative. If $v_0<v\leq v_M$, then the two roots are negative; therefore in this case we are allowed to state that the atom moves nearer to the observer.

The preceding conclusions can be applied to the case of the spectra emitted by the atoms of moving stars. So, if we know only the Doppler shift of a moving star we are not allowed to calculate the value of its radial velocity, except when the star is not a relativistic one ($u\ll c$) or when its transverse velocity is negligible compared with the radial velocity. Thus, if we consider the redshift of the spectral lines of extragalactic nebulae (corresponding to the case $a>1$), then this redshift alone cannot be a proof of the expansion of the universe.

I thank Professor Phan Van Loc for his advice and encouragement, and Dr J. Lebreton and Dr J. F. Roux for discussions.

Reaction of Carbon and Sulphur Isotopes in Apollo 11 Samples with Solar Hydrogen Atoms

Kaplan and Smith[1] have observed that the lunar fines are significantly enriched in the heavier isotopes of carbon (^{13}C) and sulphur (^{34}S) with respect to the same isotopes in fine-grained basaltic rocks of the Apollo 11 landing site in the Mare Tranquillitatis. As a consequence they suggested that this effect may be caused by the removal of lighter isotopes (^{12}C and ^{32}S) from the unshielded lunar surface by the action of the solar wind. The mechanism of removal is thought to involve the conversion of ^{12}C and ^{32}S into $^{12}CH_4$ and $H_2{}^{32}S$, which are subsequently lost from the Moon. On the other hand, it has been pointed out at the Lunar Science Conference for Apollo 11 (January 5–8, 1970, Houston, Texas) that the solar wind may actually deposit isotopically heavier carbon on the lunar surface which then might account for the observed enrichment in the lunar fines.

Libby[2] has proposed that the Moon appears grey and essentially colourless because the solar wind brings in hydrogen from the Sun. Accordingly, the solar wind bombards the lunar surface with a velocity of about 300 km/s or more and a density of some five hydrogen nuclei per cubic centimetre[3]. After neutralization with electrons, the equivalent of 10^8 hydrogen atoms/cm²/s with an energy of 450 eV are available for chemical reactions on the Moon's sunlit side. Such conditions amount to an extremely effective chemical reducing environment. This assessment is supported by chemical analyses[4,5] of iron oxides of Apollo 11 material which are almost completely composed of FeO and not Fe_2O_3.

The deposition of carbon on the Moon is likely to involve two independent processes. The first involves transport by the solar wind, which can be estimated by combining solar wind data with those for elemental abundances in the solar system or the universe. If the solar wind is essentially of the same composition as the outer solar atmosphere, then data derived from the Sun's gaseous envelope weigh more heavily than cosmic abundance values. Table 1 lists the abundances of carbon and hydrogen for comparison.

Table 1. ABUNDANCES OF CARBON AND HYDROGEN IN ATOMS/10^4 ATOMS SILICON

	Solar atmosphere[6]	Cosmic abundance[7]
Hydrogen	$3{\cdot}2 \times 10^8$	4×10^8
Carbon	$1{\cdot}66 \times 10^5$	$3{\cdot}5 \times 10^4$

The carbon addition to the Moon based on the hydrogen content of the solar wind and hydrogen–carbon abundances can thus be calculated to be 5×10^4 (solar abundance) or 10^4 (cosmic abundance) atoms/cm²/s. Over a period of $4{\cdot}5\times10^9$ yr such a carbon contribution amounts to 140 or 28 mg/cm². Several investigators[8-10] have conducted simulation experiments involving interaction of solar wind with solids, and they conclude that the retention of different implanted atomic species is very high. Consequently we may assume that most solar wind carbon will be retained by the lunar surface. Shoemaker *et al.*[11] have calculated the median thickness of the regolith at Tranquillity Base to be 4·1 m. Supposing complete mixing within this regolith of density 1·6, the mean concentration of solar wind carbon[12,13] would be 214 or 43 p.p.m. Further, the carbon isotopic composition of the solar wind is uncertain, so that no precise estimate of the $^{13}C/^{12}C$ ratio can yet be made.

A second process placing carbon on the lunar surface involves the addition of about 2 per cent of carbonaceous chondrite-like material to the lunar soil[14]. Such material may contain about 1 per cent of carbon, resulting in a further admixture of 200 p.p.m. The $^{13}C/^{12}C$ ratio has been measured for a number of carbonaceous chondrites and varies from −18·8 to +64·4 parts per thousand with respect to the PDB standard[15,16]. It is not certain, however, what the average $^{13}C/^{12}C$ ratio is for all carbonaceous chondrites and cometary debris in the solar system, because the number and types analysed may not be representative; yet the average meteoritic $^{13}C/^{12}C$ ratio based on available data is near +20 parts per thousand, not unlike the range of +17·2 to +20·2 parts per thousand for the lunar bulk fines measured by Kaplan and Smith.

The total carbon concentration in the fines must be the sum of both processes including the native carbon content. Lunar rocks, from which the fines must be derived, contain 11–77 p.p.m. of total carbon[1] with other investigators[17] favouring 64–70 p.p.m. This then is taken to be the indigenous carbon concentration at Mare Tranquillitatis. The total carbon concentration should therefore range from 239 to 417 p.p.m., but the measured value is in the 100–200 p.p.m. range[18-20].

The question thus arises: what has happened to the missing carbon? Apparently solar wind noble gases are not all quantitatively captured or retained, but a 50 per cent loss of carbon seems to be too great for a non-gaseous element.

Returning to the effect of solar hydrogen, as well as its reducing character the high impact velocity must be considered. This leads both to implantation and to radiation damage of minerals in exposed surfaces, foremost in the lunar fines, in which imbedded atoms penetrate to a depth[21] of some hundreds of Å. Because bonds involving ^{12}C or ^{32}S atoms are weaker than those involving ^{13}C or ^{34}S, decomposition is more likely to affect the light isotopes. As a result of lower zero point energy, more energy is required to break a heavier isotope bond than a similar bond extended from a lighter one. Consequently, isotope effects must be expected which are generally greatest for the lightest elements and which decrease with increasing temperature. The following reaction scheme is proposed with the understanding that some of the sulphur may sublime directly and account for its low presence:

Solar protons → Decomposition of minerals with attendant isotope effect and acquisition of loosened electrons by solar protons → Reaction of hydrogen with preferentially exposed ^{12}C and ^{32}S → Liberation of $^{12}CH_4$ and $H_2{}^{32}S$

The maximum ratios in specific rate constants at 300 K between different isotopes of the same chemical element have been calculated by Bigeleisen[22]. For the pair ^{12}C, ^{13}C the ratio is 1·25, and for ^{32}S, ^{34}S about 1·03 (Bigeleisen, personal communication). These values are strictly a guide of what to expect at most for the lunar chemistry of the Apollo 11 landing site. It is particularly important to emphasize that we do not know the precise chemical composition of all the carbon and sulphur compounds in this location. The lunar fines, however, provide a much larger surface area than the rock pieces examined. The fines should therefore be depleted more so in the lighter isotopes of carbon and sulphur. This difference between carbon and sulphur isotopes is indeed reflected in the analysis of the Apollo 11 samples reported by Kaplan and Smith[1]. The δ^{13}C values relative to the PDB standard of $-18·8$ to $-29·8$ parts per thousand for fine-grained rock compare with $+17·2$ to 20·2 parts per thousand for the bulk fines, a difference of some 40 parts per thousand. At the same time the δ^{34}S values relative to the Canyon Diablo standard range from $+1·2$ to 1·3 parts per thousand for solid rock pieces, and from $+4·4$ to 8·2 parts per thousand for fines corresponding to a difference of some 4 parts per thousand. The δ-values for carbon and sulphur thus show a net difference of one magnitude. This is in good agreement with theoretical expectations based on maximum differences in isotopic reaction rates. Moreover, similar data obtained by the same authors on breccias are intermediate in value between those for fines and rocks. Measurements by Epstein and Taylor[23] on lunar fines and breccia are also in agreement with this work. Furthermore, it is unlikely that the isotopic differences are caused by terrestrial contamination, because the fines most likely to be affected (as a result of their large surface area) contain the heavier carbon.

The ultimate fate of the newly formed gas molecules is their escape into the almost negligible lunar atmosphere. As shown previously, the chance of a gas molecule leaving the lunar surface with a speed v in excess of the escape velocity is $1 - V_E/V$ where V_E is the lunar escape velocity of 2·38 km/s. The effective time of escape of gases in an atmosphere as a function of atomic weight has been discussed by Jastrow and Rasool[24]. Consequently the lifetime of undissociated $^{12}CH_4$ near the lunar surface can be calculated to be approximately 100 yr, while that for undissociated $H_2{}^{32}S$ is of the order of the age of the solar system. But no H_2S atmosphere has been observed on the Moon, so the effective atmospheric residence time must be considerably less. This is, most likely, because of the destructive effects of photo dissociation and the sweeping action of the solar wind. In contrast, methane and hydrogen sulphide trapped inside rocks are likely to last much longer even though methane, being a smaller molecule, will be lost more quickly by diffusion processes. Indeed, Epstein and Taylor have reported the liberation of H_2S after heating lunar rocks and detected trace quantities of methane[23].

On balance there seem to occur on the Moon several processes capable of producing a heavier isotopic composition of carbon and sulphur in finely divided soil relative to solid rock. The total proton bombardment of the Moon since the formation of the solar system is equivalent to $10^8 \times 3·15 \times 10^7 \times 4·5 \times 10^9 = 1·4 \times 10^{25}$ atoms/cm^2 equivalent to about 23 moles of hydrogen/cm^2 averaged over the entire lunar surface. It is difficult to see how such an excess coupled with considerable kinetic energy would not react with carbon or sulphur. A test of this hypothesis would be to measure the carbon content and isotopic composition of fines in the polar regions of the Moon and to compare it with that from the sunlit areas. If carbon from the poles were isotopically lighter as opposed to the Sun-exposed region, then solar wind erosion would indeed be proven.

I thank I. R. Kaplan, W. F. Libby and J. W. Smith for comments and encouragement; this study was supported by NASA.

Daily Variation of the Geomagnetic Field at the Dip Equator

THE range ΔH_A of the daily variation of the horizontal component of the geomagnetic field at Alibag (A), a low latitude station outside the influence of the equatorial electrojet, is largely caused by weakening of the ambient field on the night side rather than an enhancement on the day side[1-3]. The effect may be caused by magnetospheric drift currents which, being more than 30,000 km above the surface of the Earth, would produce almost identical effects at Alibag and Trivandrum (T), situated on the dip equator 1,100 km south of Alibag, if differences in the induced field arising from local ground conditions are ignored. On the other hand, the well known enhancement of ΔH at the dip equator is caused by the influence of the equatorial electrojet. Consequently $\Delta H_T - H_A$ must be related to purely ionospheric currents.

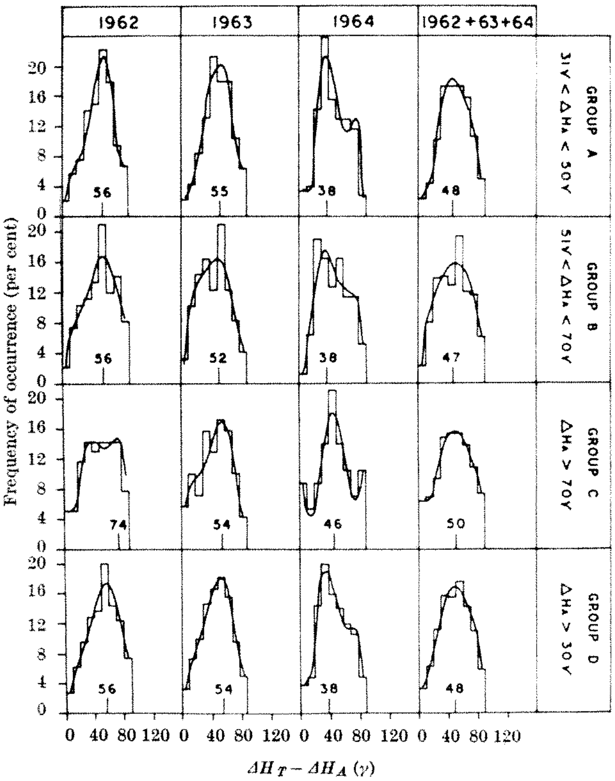

Fig. 1. The normalized histograms of (ΔH_T–ΔH_A) for different ranges of ΔH_A for the years 1962, 1963, 1964 and for all the three years combined.

We examine here the validity of these assumptions particularly because they contradict the dynamo theory, which suggests that the contribution of ionospheric currents should predominate at both stations on days which are not geomagnetically disturbed. We also estimate the relative contributions of the two processes at Trivandrum and at Alibag.

Fig. 1 shows the normalized histograms of $\Delta H_T - \Delta H_A$ for different ranges of ΔH_A for the years 1962, 1963, 1964 and for all the three years combined. On a day-to-day basis, ΔH_A is more or less independent of the purely ionospheric contribution $\Delta H_T - \Delta H_A$. Similarly, as shown in Table 1, ΔH_A is independent of the changes of F region ionospheric electron density related to the midday mean value of f_0F_2 over Kodaikanal, which is also close to the dip equator. Thus ΔH_A does not track the changes in the ionosphere.

Since January 1964, regular measurements of the electron drifts in the E and F regions of the ionosphere have been made at Thumba, near Trivandrum, by recording the fading of radio reflexions at three spaced aerials. The drift was always to the west during the day. The mean drift speed between 1100 and 1300 h correlates well with $\Delta H_T - \Delta H_A$ shown in Fig. 2. Rocketborne magnetometers have measured the magnetic field of the electrojet current in the E region[4]. R. Raghava Rao (private communication) has shown, using current density derived from similar measurements and simultaneously observed electron density, that the average electron velocity is comparable with the drift velocities measured by the spaced aerial technique. A linear relationship between the drift speed in the E region and $\Delta H_T - \Delta H_A$ is therefore consistent with the interpretation that the drift velocity measured by the spaced aerial technique is proportional to the electron drift velocity in the electro-jet and that moreover the latter, at noon, can be deduced from $\Delta H_T - \Delta H_A$, which is derived exclusively from ground measurements.

Table 1

ΔH_A range	Mean ΔH_T-ΔH_A (γ)	Mean midday f_0F_2 (MHz)	Number of days
31 to 50 γ	50	7·3	319
51 to 70 γ	51	7·6	314
71 γ and above	49	7·7	292
31 γ and above	50	7·6	925

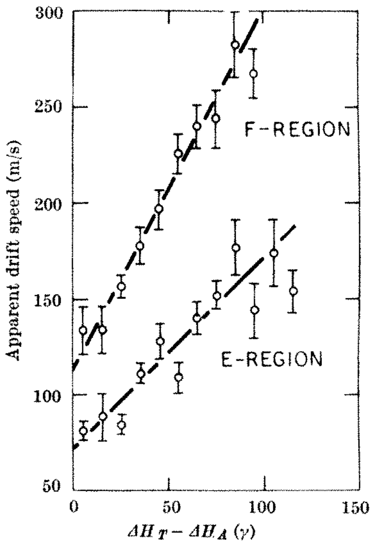

Fig. 2. The relation showing the mean westward apparent drift speed during midday hours (1100–1300 h) for different values of ΔH_T–ΔH_A.

Electron and ion currents in the F region would produce equal and oppositely directed magnetic effects, and therefore the correlation of $\Delta H_T - \Delta H_A$ with F region electron drifts indicates that the latter are themselves correlated with the E region drifts. Comparing the magnetograms from Tamale (dip 1° 14′) and Legon (dip 10° 11′), Osborne[5] has argued that the electrojet cannot be a simple enhancement of the normal current in a belt of high conductivity. Moreover, Osborne and Skinner[6] have also shown a correlation between the electrojet strength and the F region drifts. The conclusions of these authors are therefore consistent with ours.

According to the dynamo theory, the mean current density $J = \overline{\Sigma}' \cdot E$, where $\overline{\Sigma}'$ is the height integrated conductivity and E is the primary electric field. The derived values of $\overline{\Sigma}'$ for E region at 0°, 30°, 60° and 90° dip latitudes[7] enable a smooth curve to be drawn to express the variation of conductivity with latitudes. For this, the ratio of conductivities at Trivandrum and Alibag is derived as

$$\frac{7\cdot 58\times 10^{-8}}{2\cdot 61\times 10^{-8}}=2\cdot 9$$

Table 1 shows that the average ionospheric contribution at Trivandrum is about 50γ. Consequently, the average ionospheric contribution to ΔH_A would be $50/2{\cdot}9 \approx 17\gamma$.

The monthly mean values of $\Delta H_T - \Delta H_A$ and ΔH_A are shown in Fig. 3 separately for the years 1961, 1962, 1963 and 1964, and for the four years all together, along with the midday mean values of f_0F_2 at Kodaikanal, which is also close to the dip equator. $\Delta H_T - \Delta H_A$, which is purely a result of ionospheric currents, shows clear equinoctial maxima. Drifts at Thumba also exhibit equinoctial maxima[8]. In contrast with the purely ionospheric effect, ΔH_A has no consistent seasonal variation.

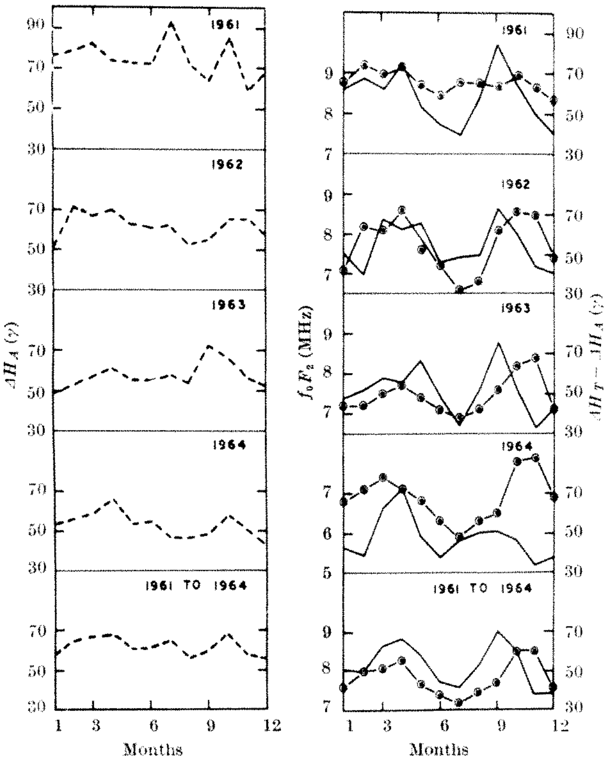

Fig. 3. The monthly mean values of ΔH_A, $\Delta H_T - \Delta H_A$ and f_0F_2 at Kodaikanal for the years 1961, 1962, 1963, 1964 and for all the four years combined. - - - -, ΔH_A; ——— $\Delta H_T - \Delta H_A$; ●—●, f_0F_2.

According to Hones and Bergeson[9], a radial electric field generated by the wobbling of the Earth's magnetic axis in the magnetosphere, distorted by the solar wind, should cause charged particles to experience net energy changes over a number of revolutions around the Earth. From this theory, an explanation for the enhancement of the equatorial electrojet at equinoxes can be visualized. Assuming that the kinetic energy density of the solar wind, which compresses the magnetosphere in the sub-solar direction, is constant over a period of one year, the Earth's magnetic axis is more nearly perpendicular to the solar wind flow at equinoxes than at solstices. The compression of the magnetosphere and the radial electric field produced in the ionosphere is therefore a maximum during equinoctial months. This effect should be more pronounced at the equator than at higher latitudes.

We conclude that the contribution to ΔH_T at Trivandrum, which can unambiguously be attributed to an ionospheric current, remains largely unaffected by the magnetospheric contribution at both Trivandrum and Alibag. This supports the contention that two independent processes are operating. While at Trivandrum the ionospheric contribution is similar in magnitude to the magnetospheric contribution on a normal day, at Alibag the ionospheric contribution is only about a third of the magnetospheric effect. Moreover, our results support the view that drift velocities measured by the technique of spaced aerials are related to the velocity of electrons in the electrojet.

We thank Mr B. N. Bhargava, director of Alibag and Colaba Observatories, for supplying the magnetic data, Dr M. R. Deshpande, who collected the ionospheric drift observations at Thumba and Dr R. Raghava Rao for discussions. This work was supported by the Department of Atomic Energy.

"Two-way Stretch" of Sialic Crust and Plate Tectonics in the South-west Pacific

Analyses of seismic and continuous gravity measurements over the northern Tasman Sea[1] have confirmed the existence of "quasi-continental" crust (20–26 km thick) beneath the parallel ridges—Norfolk Ridge, Lord Howe Rise and Dampier Ridge—that extend north-westward from New Zealand (Fig. 1). The intervening major trough, New Caledonia Basin, is shown to have a floor of true oceanic thickness (9 km).

The recognition of a crustal thickness of 20 km along Dampier Ridge is particularly important, for it effectively invalidates van der Linden's[2] interpretation of this morphological feature as an extinct or dormant mid-ocean ridge. Apart from seismic activity and high heat-flow values, mid-ocean ridges are distinguished[3,4] by crustal thicknesses less (usually much less) than those of the normal ocean floor. It is inconceivable that a relatively thick crustal segment like Dampier Ridge could have operated as a centre of sea-floor spreading during Cainozoic or late Mesozoic times.

Also inconsistent with evolution as a mid-ocean ridge are the asymmetric location of Dampier Ridge within the narrow northern neck of the Tasman Basin and its abrupt termination at the point where the latter broadens and where sea-floor spreading between Australia and New Zealand has obviously been at a maximum. Moreover, detailed examination of the local bathymetry reveals that the southern end, at least, of Dampier Ridge is linked with Lord Howe Rise at depths greater than 3,000 m. Dampier Ridge clearly represents a segment of sialic crust, structurally and genetically analogous to Lord Howe Rise and Norfolk Ridge. Because of negative seismic[5] and heat-flow[6] data from the north Tasman Sea, van der Linden's interpretation is based solely on morphology and an apparent symmetry of low amplitude geomagnetic anomalies across a narrow section of Dampier Ridge. It is not shown that the geomagnetic pattern of Dampier Ridge is significantly more symmetrical than that of Lord Howe Rise[7] or Norfolk Ridge[8]; neither is the possibility considered that other mechanisms might participate in the development of geomagnetic anomaly patterns.

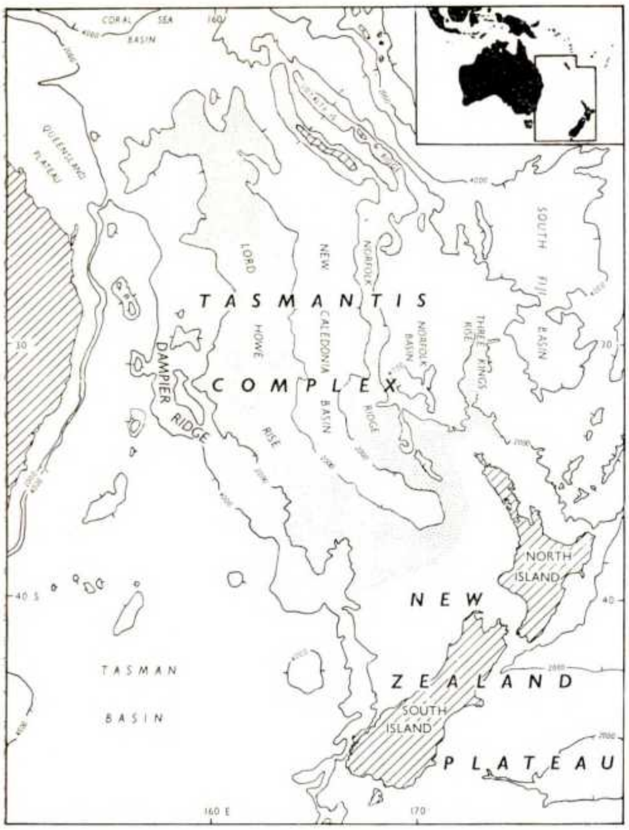

Fig. 1. Sketch-map of the submarine morphology of the Tasman Sea, showing the main ridges (stippled) and basins of the Tasmantis Complex. Landmasses shaded. Only the 2,000 m and 4,000 m isobaths are shown.

An alternative explanation of the structural relationships of the parallel ridges and basins north-west of New Zealand (collectively termed the "Tasmantis Complex"[9]) is proposed here. Expressed simply, the ridges of the Tasmantis Complex are regarded as segments of sialic crust of intermediate thickness, separated from the eastern margin of the Australian craton and rifted apart—in a manner comparable with the spreading of fingers of a hand—by mantle convection currents migrating in a general north-eastward direction from the Indian–Antarctic mid-ocean ridge, south of Australia[10,11]. The intervening long, narrow basins that developed during this process are presumably floored, as in the case of New Caledonia Basin[1], by newly formed crust of oceanic or near-oceanic thickness. Concomitant widespread extrusion of basaltic lavas on the flanks, and even the crest, of the resultant ridges is envisaged as producing crudely symmetrical geomagnetic anomaly patterns, reminiscent of mid-ocean ridges.

The Tasmantis Complex structure has been further complicated by differential northward displacement of Australia with respect to the New Zealand crustal segment. Since the disruption of Gondwanaland, northward migration of Australia has greatly exceeded that of the New Zealand Plateau, although the geomagnetic chronology derived for the south-west Pacific by Heirtzler *et al.*[12] demonstrates that the separation of Australia from Antarctica postdated that of New Zealand by some 40 m.y.

The Tasmantis Complex, spanning the gap between Australia and the New Zealand Plateau and formerly continuous with the Queensland Plateau and New Guinea[9,10,13], has consequently been subjected to intense stress. This is manifested by the sharp northward swing in strike of its component ridges and basins as the Australian coast is approached, by the development of multiple NW–SE fractures traversing the ridges in response to northward extension, and by the wrenching apart, on either side of the Coral Sea Basin, of the New Guinea and Tasmantis ridges, with the abrupt termination of the latter at latitude 18°–19° S.

These effects were accompanied by the attenuation of Norfolk Ridge and the northward extension and eventual disruption of yet another ridge farther east, separated remnants of which are now represented by Loyalty Islands Ridge and Three Kings Rise. The latter is here regarded as a sialic segment comparable with the other Tasmantis ridges and not, as van der Linden[2] claims, a possible second extinct mid-ocean ridge. Interpretation of Three Kings Rise and Dampier Ridge as extinct mid-ocean ridges is also excluded by the complete absence of any evidence of crustal compression such as trench formation in the region between the two ridges. The available data suggest that the region is in fact dominated by N–S and E–W tension.

The parallelism of the Tasmantis ridges and basins can probably be attributed, in part at least, to regional structural control by a system of Palaeozoic–Mesozoic geosynclinal and geanticlinal belts along the eastern periphery of the former Gondwana supercontinent. An intermediate stage in the evolution of the Tasmantis Complex may, however, have involved the development of parallel north–south megashear zones resulting from the differential northward migration of Australia. As suggested by Standard[14], the seamount chains of the north Tasman Sea probably represent such major shear zones in the thin oceanic crust. The formation of the alternating sialic ridges and oceanic basins of the Tasmantis Complex can be explained by subsequent expansion of the belts of crustal weakness, thus created, by north-eastward spreading mantle convection currents emanating from the Indian–Antarctic Ridge. The eastward limit of these currents, which are still active, is marked by the seismic Kermadec, Tonga and New Hebrides island arc and trench system.

The mechanism described here provides an explanation of the known structural and morphological features, the crustal thicknesses, and the seismic and heat-flow zonations in the south-west Pacific. It is considered preferable to van der Linden's assumption of extinct mid-ocean ridges at Dampier Ridge and Three Kings Rise, which is neither consistent with recent data nor helpful in clarifying the evolution of the very active island arc–trench system of the south-west Pacific and its associated Benioff zone[15]. In that they deal with the interrelationships of adjoining segments of sialic and oceanic crust in a critical sector of the Earth's surface, and raise the possibility of spreading of marginal sialic crust as well as of purely oceanic crust, the opinions stated above have implications for the concepts of sea-floor spreading and plate tectonics.

Magnetized Basement Outcrops on the South-east Greenland Continental Shelf

Most continental shelves are included in the "Pacific" and "Atlantic" categories[1]. The Pacific type marks lines along which lithospheric plates underthrust or move past one another along strike slip faults. It is not surprising, therefore, that such shelves are characterized by irregular relief, vulcanism, faulting and great seismicity. The Atlantic type represents edges of continents that were once contiguous but have been rifted apart by plate movements, with new oceanic crust created between the rifted edges by sea-floor spreading. Most shelves of the Atlantic type are depositional. A wedge, thickening towards the sea, of largely undeformed Cretaceous and younger sediments along the eastern United States attests to gradual subsidence.

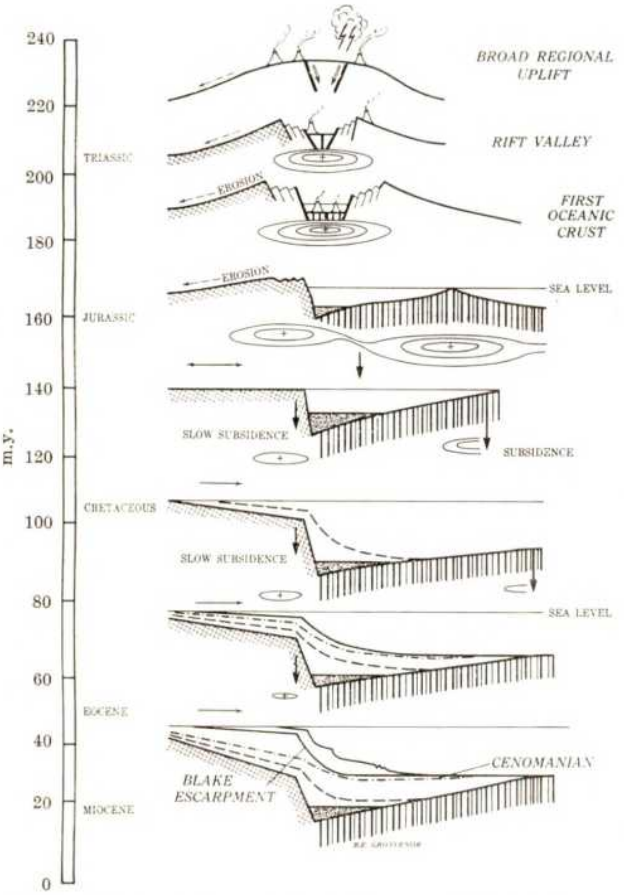

Fig. 1. Evolution of rifted continental margin in central North Atlantic. The continental basement subsides by erosion, and the disappearance of the thermal anomaly is inherited from the initiation of rifting. Note that the basement reaches sea level 50 to 100 m.y. after the ocean basin forms. Further subsidence is accelerated by sediment and water loading. Based on refs. 2 and 3.

Ostenso and I[2] have suggested that the initial margins of the continents, at first warped upwards, are in time reduced to sea level by erosion and thermal contraction (about 100 m.y. after the beginning of rifting in the central North Atlantic). Further subsidence may reflect sediment loading near the edge of the shelf and continued subsidence because of thermal contraction by cooling. The hypothesized evolution of the North American continental margin, based on the above premises, is shown in Fig. 1 (taken from Schneider[3]).

If this hypothesis is correct, it is reasonable to expect to observe margins in various stages of development at the present time. The East African rift is represented by the first two depicted stages, and the Red Sea by the third.

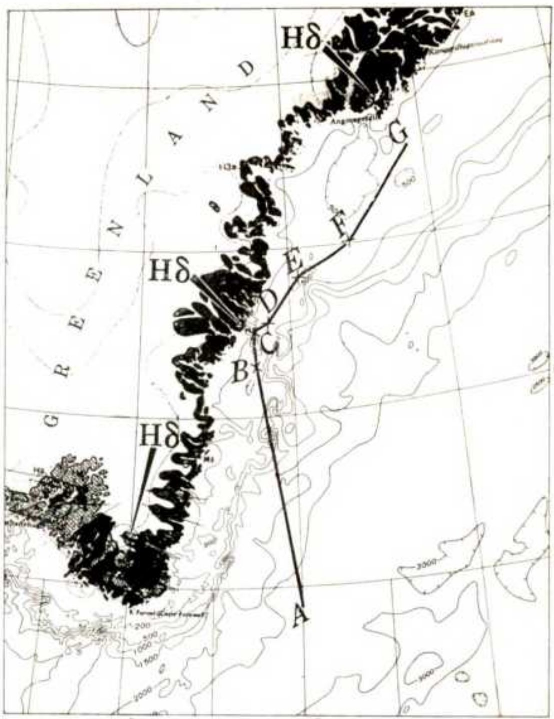

Fig. 2. Location of bathymetric–magnetic traverse (*A–G*) across south-east Greenland shelf, and adjacent coastal geology[6]. Black denotes Archean gneisses and migmatite, reworked by Hudsonian orogeny; Hδ denotes post-orogenic granitic intrusives.

So far most margins of the Atlantic resemble the last three stages of Fig. 1, with igneous or metamorphic basement complexes usually deeply buried under the seaward reaches of continental shelves.

A bathymetric–magnetic traverse across the south-east Greenland shelf (Fig. 2) seems to reveal the fourth or fifth evolutionary stage of Fig. 1. The regions of rough, short-wavelength topography and magnetic anomalies suggest where basement is probably exposed (Fig. 3). An eroded basement surface has been lowered to sea-level but is not yet buried by a wedge of sediments younger than the rift that separated Scandinavia and the British Isles from Greenland. The age of the oldest ocean floor between Greenland and Rockall–Hatton Bank has now been confidently dated[4] at 60 m.y. BP.

We should thus expect the margins of the Norwegian Sea to be going through the stage that the north central Atlantic had achieved by Jurassic times, that is, after the oceanic basin was already of the order of 60 m.y. old (Fig. 1).

The bathymetric–magnetic traverse (Figs. 2 and 3) also yields some conclusions more specifically related to Greenland. The sea-floor topography of the shelf consists of broad depressions (probably glacial valleys carved when the sea level was lower[5]) with widths of about 50 km and depths about 400 m below the average shelf levels. These features also occur farther north along the Greenland coast and in other glaciated areas[5].

There are two varieties of shelf micro-topography—rough and smooth (Fig. 3). The rough type exhibits amplitudes of 50 to 100 m and wavelengths of a few km or less. Near *E* there is rough small-scale topography within a broad valley. Most probably these undulations are glacially abraded, igneous and metamorphic shield rocks similar to the predominant Archean gneisses and migmatites, reworked by the Hudsonian orogeny[6], that are exposed on the nearby mainland (Fig. 2). The vigorous East Greenland current scours the shelf and may help to keep sediments from burying the topography. The rough basement is associated with magnetic anomalies of similar wavelength, with amplitudes up to several

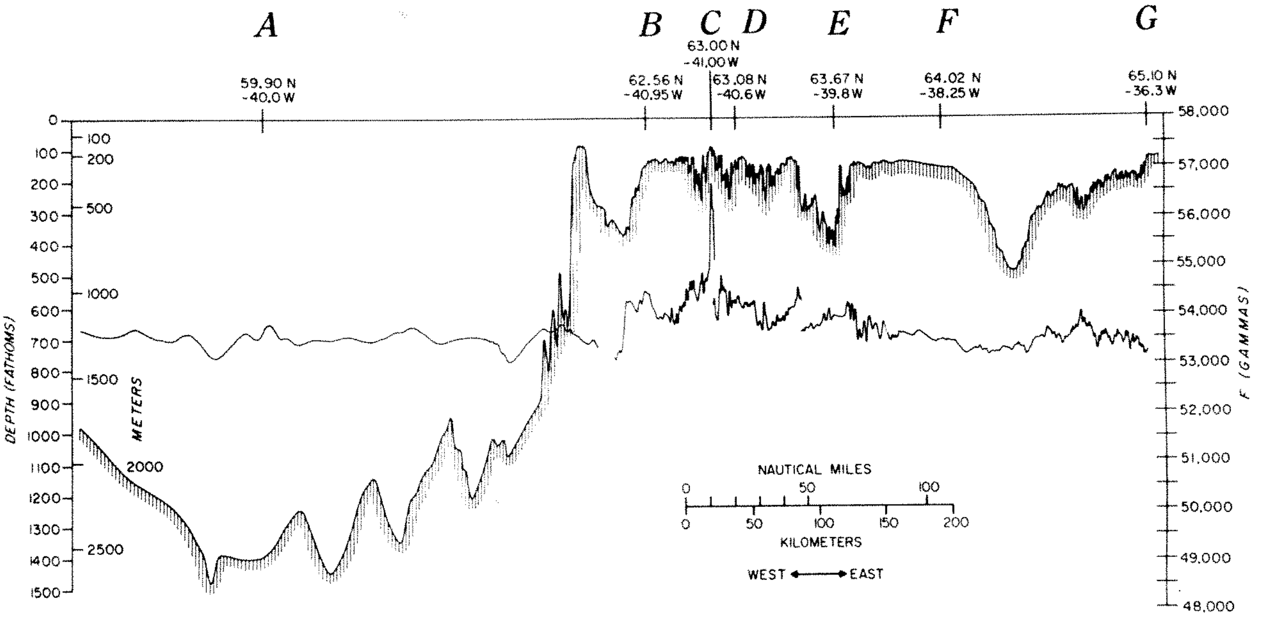

Fig. 3. Bathymetric (shaded) and total magnetic field profile across south-east Greenland shelf. Position of track shown in Fig. 2 (*A*–*G*).

hundred gammas. A sea-floor high near the coast at *C* is associated with a conspicuous 2,800 gamma anomaly.

The smooth micro-topography is in general associated with a smooth magnetic field, suggesting relatively uniformly magnetized or weakly magnetized metamorphic and sedimentary formations. Possibly the magnetized basement has been downfaulted and covered by younger sediments. To some degree the correlation between anomalous magnetic field and topography may imply the existence of a rather uniform highly magnetized (basaltic ?) layer, with the anomalies resulting from relief characteristics on this surface. The Keweenawan basalts in northern Wisconsin exemplify this case[7]. In the present example, however, the magnetically disturbed shelf areas occur offshore from granitic intrusions, and complex high-amplitude anomalies are likely to occur in the vicinity of such intrusions because of a complex and highly variable magnetization[8]. The granitic intrusions on the Greenland coast are reported to be Sanerutian or younger. Some may even be lower Tertiary in age, by analogy with the dated (60 m.y. BP) Rockall granite[9,10], which was very near the Greenland intrusions about 60 m.y. BP[4], and which also exhibits a circular region of high amplitude, short-wavelength magnetic anomalies around its centre[11].

Another explanation for the short-wavelength magnetic and bathymetric features is that they reflect dike swarms, probably early Tertiary in age, similar to those observed along coastal Greenland in the Tertiary basalt province[12]. The density of dikes (10 to 100 per mile[12]), their high magnetization, and their probable resistance to erosion make them an attractive explanation, although there is no other evidence of Tertiary dike swarms so far south of the basalt province.

"Pan African Orogeny" in the Coastal Region of Ghana

SEVERAL authors[1-4] have advocated that in West Africa the 500–600 m.y. "Pan African Orogeny"[5] was a complete orogenic cycle and not merely a thermal event that caused isotopic changes. It has been postulated that in Ghana[3,4] this cycle began when the Birrimian rocks, which had been involved in a previous orogeny between 1,700 and 2,000 m.y. ago, became the basement to a sedimentary cover sequence comprising the Togo (Akwapimian, Atacorian) and Buem Formations and lower parts of the Voltaian Group (Fig. 1) which are in part laterally equivalent to one another and in which there is a south-eastward transition from miogeosynclinal to eugeosynclinal facies. The cover and basement to the south-east of a line running approximately between Accra and Niamey (inset of Fig. 1) were then involved in the thermo-tectonic phase of the "Pan African Orogeny" while that to the north-west remained essentially undisturbed as part of the West African craton. Within the orogenic zone the cover was strongly folded and thrust on south-easterly dipping planes, was lightly metamorphosed, and perhaps locally subjected to granitization[6,7] and to granite intrusion, while the Birrimian basement was reactivated to give the unit known as the Dahomeyan.

One essential part of this hypothesis is that in the orogenic zone the Birrimian was reactivated (that is, the rocks were presumably deformed and metamorphosed again) at the same time as the cover sequence was being folded, thrust and metamorphosed for the first time. This has yet to be substantiated by a detailed analysis of the thermo-tectonic evolution of the rocks involved.

The coastal strip of Ghana is well suited for such an analysis, being a relatively well exposed cross-section from the Birrimian of the West African craton in the west and centre, through the Togo Formation in the southern extension of the Atacora–Togo–Akwapim Range in which the formation is supposed to have been effected by the orogeny, to the Dahomeyan (reactivated Birrimian) in the east. A programme of research is in progress in this coastal region to establish the tectonic and metamorphic evolution of the Togo Formation which will then represent the effects of the "Pan African Orogeny" on the cover in the region. A second aim is to recognize these effects on the Dahomeyan. In this way it is hoped that the tectonic and metamorphic history of the Dahomeyan before the "Pan African Orogeny" can be determined and then compared with that of the Birrimian in the craton; according to recent interpretations these histories are closely similar. So far only the Togo Formation and Dahomeyan have been studied in any detail, but already results are available which are not in agreement with current opinion and cast doubt on the concept of a complete orogenic cycle having taken place in this region 500–600 m.y. ago. A full account of these two units is in preparation and, in the meantime, the principal points and conclusions are outlined here.

The sequence of deformational and metamorphic events in the Togo Formation and Dahomeyan is summarized in Table 1, where a correlation of events is also made between the two units. It is thus clear that the Dahomeyan had suffered at least two phases of intense deformation (DF_1 and DF_2) before the deposition of the Togo Formation and that the earlier phase was accompanied by moderate to high grade metamorphism. The regional schistosity in the Dahomeyan was produced during the earlier phase, while the flat-lying attitude of the schistosity was the result of the recumbent folding of this fabric during the second phase. In contrast to previous ideas, therefore, neither the regional Dahomeyan schistosity nor its attitude is related to any phase of deformation which affected the Togo Formation, and so neither can be in any way attributed to the "Pan African Orogeny".

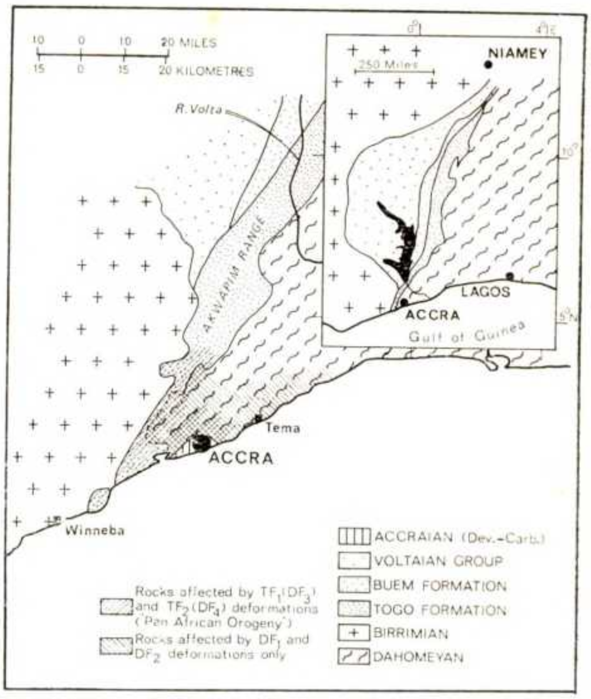

Fig. 1. Regional distribution of the Voltaian Group, Buem and Togo Formations, Birrimian and Dahomeyan in central West Africa (inset) and in the coastal region of Ghana.

There is also evidence in south-east Ghana to oppose the idea that the deformation associated with the orogeny increases in intensity from north-west to south-east from the craton into the orogenic zone. On the contrary, there is no indication that the Dahomeyan rocks in the coastal region were deformed during the two tectonic episodes which affect the Togo Formation (TF_1 and TF_2) except in the area immediately adjacent to the outcrop of the formation in the Akwapim Ridge and in windows through the formation (Fig. 2). Moreover, while these two tectonic phases exerted a strong influence on the morphology of the region by producing the north-east–south-west topographic grain in the prominent Akwapim Ridge, they were very mild from a deformational point of view, giving rise to only small strains and only local penetrative tectonic fabrics. Further, the low greenschist facies metamorphism which accompanied the first phase is related more to deformational processes than to a regional metamorphism resulting from a general temperature rise during an orogeny.

In the light of these results it seems that the concept of the 500–600 m.y. event involving a complete orogenic cycle in Ghana at least needs to be reconsidered in the light of detailed tectonic and metamorphic evidence obtained from the rocks involved. I do not question here that the geosynclinal stages of an orogenic cycle are manifested in the cover sequence, but I do contest that two minor phases of deformation, which are not accom-

Table 1. SEQUENCE OF DEFORMATIONAL AND METAMORPHIC EVENTS

	Dahomeyan	Togo Formation
"Pan African Orogeny"	DF_4. (Immediately adjacent to and in windows through the Togo Formation of the Akwapim Ridge.) Upright fold of DS, schistosity and DS_2 boudinage on NNW/SSE axial planes, hinges plunging gently N. Monoclinal flexures, open small-scale folds, kink bands and crenulation cleavage. Possibly major open Nungua Anticline related. Insignificant metamorphism.	TF_2. (Local development.) Upright folds of bedding and TS_1 slaty cleavage on NNW/SSE axial planes. Typically gentle flexure folds but local chevron folds and kink-bands. Insignificant metamorphism.
	DF_3. (Immediately adjacent to and in windows through the Togo Formation in the Akwapim Ridge.) NE/SW striking axial planes dipping mainly to SE at moderate angles but local conjugate set dipping NW. Typically open monoclinal flexures of DS_1 schistosity but set with SE dipping axial planes locally tight to isoclinal with rare DS_3 axial plane slaty or crenulation cleavage. Insignificant metamorphism.	TF_1. (Widespread.) Axial planes strike mainly NE/SW and dip SE at moderate angles but considerable variation. Plunge mainly NE in Akwapim Ridge but variable in the coastal section proper. Typically gentle flexural folds of bedding but locally tight with TS_1 axial plane slaty cleavage in SE flank of Akwapim Ridge. Syntectonic very low greenschist facies metamorphism.
	DF_2. (Widespread development.) Axial planes strike mainly NW/SE, dipping gently to NE; hinges plunge mainly to N at low angle but subsidiary maximum plunge E/W. Recumbent tight to isoclinal folding of DS_1 and bedding. Contemporaneous boudinage of bedding and DS_1 fabric on axes plunging mainly N at low angles. Very local development of DS_2 axial plane slaty or crenulation cleavage. No significant metamorphism.	
	DF_1. (Widespread development.) Original axial plane orientation unknown because of subsequent deformation—now flat-lying. Hinges plunge mainly to NW or N at low angles. Isoclinal folds of bedding with strong regional DS_1 axial plane schistosity and B-lination. Syn- and latectonic metamorphism in epidote amphibolite and granulite facies.	

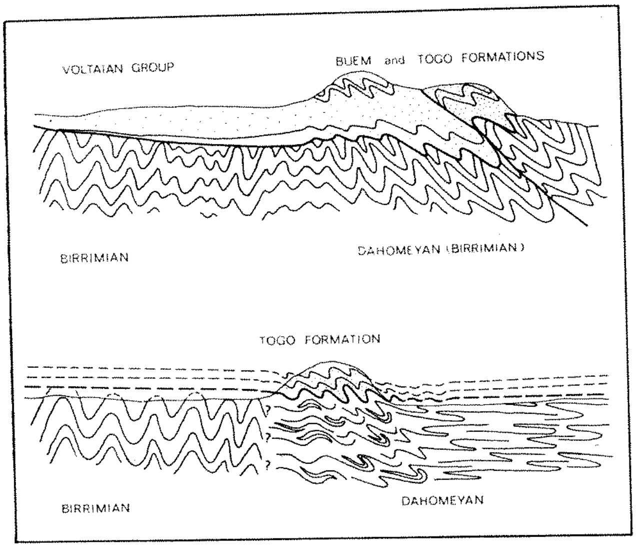

Fig. 2. Diagrammatic NW to SE sections from Birrimian of the West African craton overlain by undisturbed cover to deformed cover and Dahomeyan. Upper section through central Ghana as interpreted by Grant[4], and lower section through the coastal region of Ghana as interpreted here.

panied by any significant metamorphism and do not affect the basement more than locally, should be given the status of a full tectonothermal phase in an orogenic cycle. It is therefore impossible to accept the idea that the Dahomeyan rocks are those of the Birrimian which were deformed and metamorphosed again to a degree sufficient to give them their present very different aspects.

I thank the University of Ghana for financial support for this project.

Pattern of Relative Motion from Fracture Zone and Spreading Rate Data in the North-eastern Pacific

THE concepts of sea floor spreading and plate tectonics provide a useful framework within which to examine the tectonic history of oceans and continents[1–4]. In these new theories, the Earth is envisaged as a complex mosaic of rigid plates in constant interaction and the instantaneous relative motion between any two of these plates can be represented by a rotation about a pole. Morgan[3] pointed out that sections of fracture zones should follow small circles centred about such poles. This generalization is useful in deriving the path of continents which have been separated by continental drift, for the fracture zones mark the lines of movement.

Although, to a first approximation, continental drift can be described by a small number of finite rotations about different poles, it has not been demonstrated that such a simplified model is a valid representation of reality. The largest (and unique) portion of the ocean floor where the bathymetry has been mapped in extraordinary detail and the pattern of magnetic anomalies has been well recognized is the north-eastern Pacific (ref. 5 and unpublished work of H. W. M. with T. C. Chase). This portion of the ocean floor, which comprised two plates, is thus an excellent area in which to analyse the pattern of relative motion between two large plates.

At least five different directions have been recognized for the major fracture zones in the north-eastern Pacific (ref. 6 and unpublished work of H. W. M. with T. C. Chase). When these fracture zones are aligned according to the younger of the two anomalies on either side, the changes of direction pointed out by H. W. M. and Chase (unpublished) align surprisingly well (Fig. 1). This strongly suggests that these changes of direction, being contemporaneous, reflect true changes of relative motion between the north-east Pacific and Farallon plates[7]. Fracture zones of correlatable trend lie between magnetic anomalies 10–16 (phase 1), 16–25 (phase 2) and 25–32 (phase 3). Two other phases (phases 4 and 5) can be distinguished on portions of the ocean floor older than magnetic anomaly 32.

A pole of relative rotation that best fits the orientation of the fracture zones for each phase was calculated. This pole minimizes, in the least squares sense, the angular distance between the pole and the points in each fracture zone. It was determined by a search method and corresponds to the minimum value of the pooled estimate of the standard deviation of the angular distances. The 95 per

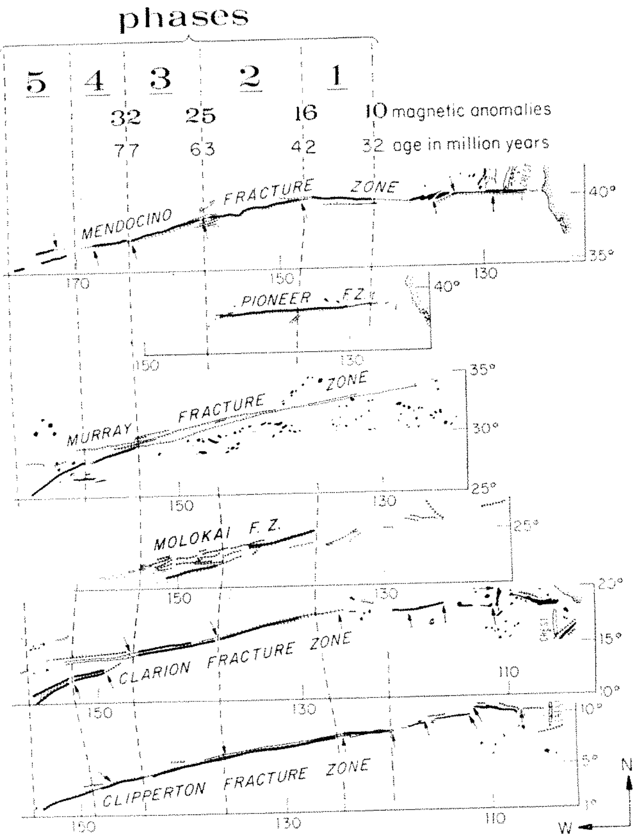

Fig. 1. Fracture zones in the north-eastern Pacific aligned by the younger of the two anomalies on either side of the fracture zone. The arrows are the changes of direction of H. W. M. and Chase (unpublished). The heavy black line represents the sections of the fracture zones used to compute the poles. The Murray fracture zone has not been considered for phases 1 and 2. During this time interval it behaved as a leaky transform fault and there was a jump in the spreading centre below the Murray[8].

cent confidence limit on the minimum standard deviation enables an oval of confidence to be drawn around the best fit pole. The computed ovals of confidence are large and elongate (Fig. 2). The poor estimate of the small curvature results in a large major axis perpendicular to the direction of the fracture zones. In contrast, the control in the position of the poles of relative motion in a direction parallel to the fracture zones is good. The ovals do not intersect and so the poles of relative motion are significantly different from one another with the exception of phase 2 and phase 3 where the fracture zone data are ambiguous.

Fig. 2. Poles of relative rotation north-east Pacific/Farallon. Mean and 95 per cent band of confidence for the angular distance of the pole of relative rotation north-east Pacific/Farallon are determined from the spreading rates for magnetic anomaly intervals 8–13, 13–21, 23–32. Also shown are the pole (black dot) and oval of confidence for the fracture zone data for magnetic anomaly intervals 10–16, 16–25, 25–32. The heavy line joining white dots represents the drift of the relative pole north-east Pacific/Farallon consistent mean with both fracture zone and spreading rate data. The points 1, 2, 3 are the positions of localities used to compute mean angular distance of pole from spreading rate data for phases 1, 2 and 3.

Because the fracture zone oval gives reasonable control on the direction on which the pole of relative rotation has to lie, it is possible to compute from spreading rate determinations the distance of a given point of spreading from this pole. Seven mean spreading rates have been measured[5] between magnetic anomalies 8–13, 13–21 and 23–32. The anomalies were selected because they are prominent and the time spans they embrace overlap sufficiently the time intervals for which the fracture zones keep a constant trend. Spreading rates are proportional to the sine of the angular distance between the pole of relative motion and the localities where spreading is measured. The distance to the pole can thus be estimated by fitting a sine curve to the measured spreading rates. The information from spreading rates provides a good control in the direction perpendicular to the fracture zones. We have estimated statistically a band at the 95 per cent level about the mean angular distance from a point of the plate to the pole after all measurements have been adjusted to this point. The estimated bands for the pole of relative motion for phases 1, 2 and 3 intersect the respective ovals of confidence obtained from fracture zone data (Fig. 2). This combined method improves greatly the control in the position of the poles (Table 1). For example, the pole positions for phases 2 and 3 are now significantly different. The poles of the relative motion, north-east Pacific/Farallon, follow a distinct path and move at least 30 degrees during the time interval covered by the north Pacific fracture zones.

Table 1. COMPARISON BETWEEN RELATIVE POLE POSITIONS NORTH PACIFIC/FARALLON DETERMINED FROM SPREADING RATES AND FRACTURE ZONES

	Fracture zones		Spreading rates and fracture zones	
Phase	Latitude	Longitude	Latitude	Longitude
1	78° N	224° E	81° N	224° E
2	82° N	138° E	77° N	185° E
3	76° N	88° E	78° N	132° E
4	61° N	185° E		
5	52° N	178° E		

Several conclusions can be drawn from this analysis. (1) Even in an area where the ocean floor has been extensively mapped, the knowledge of fracture zone trends is not adequate to specify a reliable position for a pole of relative motion (Table 1). This is largely a result of the shortness of the segments of fracture zones where the trend remains approximately constant. This point is demonstrated most clearly in Figs. 14 *a–e* of ref. 3. Where the further information of spreading rates is available the control in the pole position is greatly improved. This result casts doubt on the feasibility of tracing reliably the direction of continental drift from fracture zone surveys in the "quiet" magnetic zones of the Pacific and Atlantic Oceans. (2) The generalization that present poles of relative motion tend to cluster around the Earth's geographic pole does not seem to be true for the past motion of the north-east Pacific and Farallon plates. This is because the path of the poles of relative motion and the palaeomagnetic polar path are both fixed in a frame attached to the north-east Pacific plate and these two paths lie on opposite sides of the North Pole[8]. (3) It seems plausible *a priori* to postulate that large original offsets of the ridge crests (that is, long transform faults) could stabilize the relative motion of two plates. In the north Pacific, even though major offsets in the ridge crest were present, the movement of the north-east Pacific/Farallon poles suggests that these transform faults did not control the basic motion of either plate over a time interval of 50 to 100 m.y. (4) Because plate movements are interrelated, any major change in the pattern of spreading must be global[4]. It is therefore possible that the sharp bends in the path of the pole, north-east Pacific/Farallon, might be correlated with contemporaneous changes of the relative motion of any two other plates. In particular it would be interesting to find out whether changes in the direction of Atlantic and Indian Ocean fracture zones occur at anomaly time 10, 16, 25 and 32, and whether these changes are related to particular collisions of continents[9]. (5) The changes in the relative motion of the north-east Pacific and Farallon plates have been frequent—one every 10 to 20 m.y. The physical significance of such changes is not very clear because the driving mechanism of the plates has not been elucidated.

The north-east Pacific fracture zone and spreading rate data are consistent and indicate that rigid plate tectonics may be a valid model to use in attempts to reconstruct the past positions of continents. One further implication of the movement of the pole of relative rotation is worth stressing. It has been shown that three plates cannot rotate through finite angles about a single set of three axes of relative rotation fixed to the respective pairs of plates[4,7]. The pole of relative rotation, north-east Pacific/Farallon, has, however, not remained fixed to these two plates. If this behaviour is typical of all other plates (and recent Atlantic data suggest that this might be so: refs. 10, 11 and personal communication from B. C. Heezen), it shows that none of the relative rotations need keep constant parameters and all three rotations may adjust to each other with time[4]. This will introduce great complexity in attempting palaeogeometry. On the other hand, this extra degree of freedom may make it possible to apply large displacements to the plates of the Earth and still retain the simple boundaries of the plate theory defined by Wilson[12], McKenzie and Parker[2] and Morgan[3].

This work was supported by the US Office of Naval Research. We thank C. G. Chase for suggesting a simplified method for computing pole positions from spreading rates.

Highly Undersaturated Rocks in Upper Mantle Conditions

OLIVINE nephelinite and the closely related magmas, basanite and olivine melilite nephelinite, are products of widely distributed but small volcanic eruptions. They commonly contain dense, coarse grained xenoliths produced at high pressures in the upper mantle, particularly lherzolites, pyroxenites and garnet pyroxenites. These magmas therefore derive directly from the mantle and cannot have been modified by shallow, crustal fractionation processes[9]. It is important to know the variation of the mineralogy of olivine nephelinite as a function of pressure and temperature. Exploratory measurements using a piston-cylinder high pressure apparatus to 36 kilobars, and using techniques which have given equilibrium mineral assemblages in basaltic composition[1], have shown a variation in the mineralogy of a nepheline-rich basic composition at sub-solidus temperatures over the pressure range of the crust and upper mantle. The composition studied (Table 1) has very low albite and is classified as transitional between olivine nephelinite and nepheline-rich basanite. The results of the experiments are given in Table 2; phases were identified by X-ray powder diffraction and by optical examination. What follows is a discussion of the mineral reactions required by the data of Table 2.

Table 1. COMPOSITION OF THE SYNTHETIC OLIVINE NEPHELINITE GLASS USED IN THE EXPERIMENTAL WORK

		CIPW norm	
SiO_2	44·3	Or	6·1
TiO_2	1·5	Ab	2·0
Al_2O_3	14·2	Ne	15·3
Fe_2O_3	0·5	An	19·4
FeO	9·7	Di	26·4
MnO	0·2	Ol	25·9
MgO	13·3	Ap	1·3
CaO	11·2	Il	2·9
Na_2O	3·6	Mt	0·7
K_2O	1·0		
P_2O_5	0·5		
$\frac{100\ Mg}{Mg + Fe^{2+}}$	71·0		

The absence of detectable nepheline (amounting to less than 10 per cent) in the low pressure assemblages (4·5 kilobars, 9 kilobars), and the presence of plagioclase and spinel, can be accounted for by the following reactions, in which substitution of Fe for Mg is neglected:

$$\underset{\text{diopside}}{mCaMgSi_2O_6} + \underset{\text{anorthite}}{(n+2)CaAl_2Si_2O_8} + \underset{\text{nepheline}}{NaAlSiO_4} \rightleftharpoons \underset{\text{aluminous diopside}}{mCaMgSi_2O_6.2CaAl_2SiO_6} + \underset{\text{plagioclase}}{nCaAl_2Si_2O_8.NaAlSi_3O_8} \tag{1}$$

$$\underset{\text{anorthite}}{3CaAl_2Si_2O_8} + \underset{\text{olivine}}{2Mg_2SiO_4} + \underset{\text{nepheline}}{NaAlSiO_4} \rightleftharpoons \underset{\text{diopside}}{2CaMgSi_2O_6} + \underset{\text{spinel}}{MgAl_2O_4} + \underset{\text{plagioclase}}{CaAl_2Si_2O_8.NaAlSi_3O_8} \tag{2}$$

These reactions will limit the occurrence of nepheline in olivine-bearing plutonic rocks to very shallow depths in the Earth's crust and illustrate the equivalence of clinopyroxene + plagioclase + spinel ± olivine assemblages to olivine nephelinite.

The elimination of plagioclase between 9 kilobars and 13·5 kilobars is due to the reaction between olivine and plagioclase[2] to yield aluminous clinopyroxene solid solution and spinel. Orthopyroxene cannot be detected and calculation of the pyroxene + spinel + olivine mineralogy suggests that the clinopyroxene at intermediate pressures is largely diopside + jadeite + (Ca,Mg)–Tschermak's silicate solid solution. In the pressure interval of 13·5 kilobars to 25 kilobars the mineral assemblage is clinopyroxene + spinel + olivine with olivine decreasing in abundance in favour of spinel at higher pressure. Olivine is not detectable in the 22·5 kilobar and 24·8 kilobar runs but a mica (possibly phlogopite) is present in small quantities. The decrease in olivine and increase in spinel are attributed to the reaction of olivine with Ca–Tschermak's silicate (see equation (1)) in the clinopyroxene solid solution

$$\underset{\text{(diopside + Ca–Tschermak's silicate)}}{mCaMgSi_2O_6.CaAl_2SiO_6} + \underset{\text{olivine}}{Mg_2SiO_4} \rightleftharpoons \underset{\text{diopside}}{(m+1)CaMgSi_2O_6} + \underset{\text{spinel}}{MgAl_2O_4} \tag{3}$$

Garnet is first observed in the 27 kilobar run and garnet and olivine increase at the expense of clinopyroxene and spinel with increasing pressure. The idealized reaction (reaction (4), neglecting pyroxene solid solution) yields grossular-rich garnet. Breakdown of any Mg–Tschermak's silicate solid solution in the pyroxene may contribute a higher pyrope content to the garnet (reaction (5))

$$\underset{\text{diopside}}{2CaMgSi_2O_6} + \underset{\text{spinel}}{MgAl_2O_4} \rightleftharpoons \underset{\text{olivine}}{Mg_2SiO_4} + \underset{\text{pyrope-grossular}}{Ca_2MgAl_2Si_3O_{12}} \tag{4}$$

$$\underset{\text{(diopside + Mg–Tschermak's silicate)}}{mCaMgSi_2O_6.MgAl_2SiO_6} \rightleftharpoons \underset{\text{grossular-pyrope}}{CaMg_2Al_2Si_3O_{12}} + \underset{\text{diopside}}{(m-1)CaMgSi_2O_6} \tag{5}$$

It may be noted that the pressure required for the appearance of grossular-rich garnet in this composition closely matches that obtained for the appearance of grossular-rich garnet in the simple system (diopside + spinel[3]) and for a

Table 2. MINERAL ASSEMBLAGES FORMED BY REACTION OF OLIVINE NEPHELINITE COMPOSITION AT 1,100° C AT VARIOUS PRESSURES

Pressure (kilobars)	Temperature (° C)	Time (h)	Phases present	Comments
1 atmosphere	1,100	4	Ol + Cpx + Pl + glass	
1 atmosphere	1,000	24	Ol + Cpx + Pl	Minor plagioclase
4·5	1,100	2	Ol + Cpx + Pl + Sp + ? glass	Minor spinel. Possible incipient melting
9·0	1,100	4	Ol + Cpx + Pl + Sp + ? glass	Less olivine than at 4·5 kilobars Possible incipient melting
13·5	1,100	4	Ol + Cpx + Sp	Minor olivine, spinel increased from 9 kilobars
18·0	1,100	4	Ol + Cpx + Sp	Rare olivine, spinel increased from 13·5 kilobars
22·5	1,100	4	Cpx + Sp + mica	Olivine not detected, minor mica
24·8	1,100	4	Cpx + Sp + mica	
27·0	1,100	4	Cpx + Sp + Ga + mica	Large euhedral garnet
36·0	1,100	4	Ol + Cpx + Sp + Ga + mica	Minor olivine and spinel, rare mica

Experimental conditions are given in the first column; the mineralogy produced is listed in the fourth column.
Ol, Olivine; Cpx, clinopyroxene; Ga, garnet; Sp, spinel.

marked increase in grossular content of garnet in aluminous basaltic compositions (kyanite eclogite, grosspydite)[4]. At very high pressures, elimination of spinel from the assemblage may yield grossular-rich garnet + olivine + (omphacite). Hydrogen was not excluded from the sample and this allowed the formation of mica at pressures above 18 kilobars. Our data indicate that mica (phlogopite) may occur in the upper mantle in olivine-rich compositions at pressures in excess of 30 kbars and temperatures up to at least 1,100° C (ref. 10).

Comparison of the data with previous data in basaltic compositions[1,4] shows that, in the olivine nephelinite composition, plagioclase disappears at a lower pressure and garnet requires a very much higher pressure to form. Assemblages of intermediate and high pressure granulite facies in the olivine nephelinite composition do not consist of garnet + aluminous pyroxene + plagioclase mineralogy as is characteristic of most classes of basaltic rocks[1], but instead of clinopyroxene + plagioclase + spinel ± olivine and clinopyroxene + spinel ± olivine. The very high pressure required to form garnet contrasts with the behaviour of basaltic and peridotitic compositions and points to the stability of clinopyroxene + spinel ± olivine mineralogies in very undersaturated nephelinitic compositions in the conditions of high temperature eclogite facies (> 20 kilobars at 1,100° C). Yoder and Tilley[11] reported clinopyroxene + spinel + mica assemblages in olivine nephelinite at 31·4 kilobars and 40 kilobars, 1,200° C. The composition used (containing normative larnite) is very much more undersaturated and has a higher Fe_2O_3 content than the present composition. The differences in high pressure mineralogy are attributed to these differences in composition.

The mineral assemblages obtained in our experiments are comparable with chemically similar natural rocks (although with lower Na_2O content) crystallized as aluminous clinopyroxene + spinel + olivine and occurring as xenoliths in basanitic magma[5]. Some of these xenoliths contain garnet, but the garnet is pyrope–almandine and not grossular-rich. These xenoliths imply crystallization in the 10–20 kilobar pressure range[6,7].

The grosspydite inclusions[8] in Russian kimberlite pipes contain grossular-rich garnets and probably require pressures similar to the garnet-bearing assemblages of the olivine nephelinite. These rocks differ chemically from the olivine nephelinite in higher Al_2O_3 and lower MgO and Na_2O contents, so that intermediate pressure assemblages are of garnet + plagioclase + pyroxene and the high pressure assemblages contain kyanite rather than olivine and spinel[4,8].

In considering the origin of olivine nephelinite magmas in an upper mantle of peridotite composition, it is apparent that the mineral components of the source rock which may enter a melt to produce liquid olivine nephelinite will be mainly aluminous clinopyroxene + spinel + olivine at depths to around 100 km and may be omphacitic clinopyroxene + olivine + grossular-rich garnet ± spinel at greater depths. The evaluation of the possible mechanisms of production of olivine nephelinite liquids requires direct melting studies, but it is important that orthopyroxene and pyrope–almandine components should be enriched in the residue rather than the liquid in melting of a garnet peridotite source[9].

High-magnesian Calcite and Protodolomite in Lake Balaton (Hungary) Sediments

RECENT sedimentation in Lake Balaton is governed chiefly by two processes[1]. (*a*) Clastic material (quartz, feldspars, calcite, dolomite, phyllosilicates, heavy minerals) introduced by wind and rivers is distributed on the bed by the currents. (*b*) During the warmer seasons much fine-grained high-magnesian calcite is precipitated from the lake (average depth, 3·3 m; July average temperature, 25° C) because of the dense and extensive growth of phytoplankton. In photosynthesis CO_2 is liberated from dissolved bicarbonate, and carbonate is precipitated.

The precipitates are equant grains or aggregates of irregular shape and have rounded surfaces. About half the grains (chiefly aggregates) are 2–6·3 μm in size, and the rest smaller. The precipitates $MgCO_3$ concentrations (Fig. 1*a*) are between 6 and 8·5 mole per cent. The concentrations show a clear tendency to increase from west to east along the axis of the basin. The increasing incorporation of $MgCO_3$ into the calcite lattice (determined by X-ray methods) runs more or less parallel with an increase in the total $MgCO_3$ content of all carbonates present in the 2–6·3 μm grain class of the sediments. The

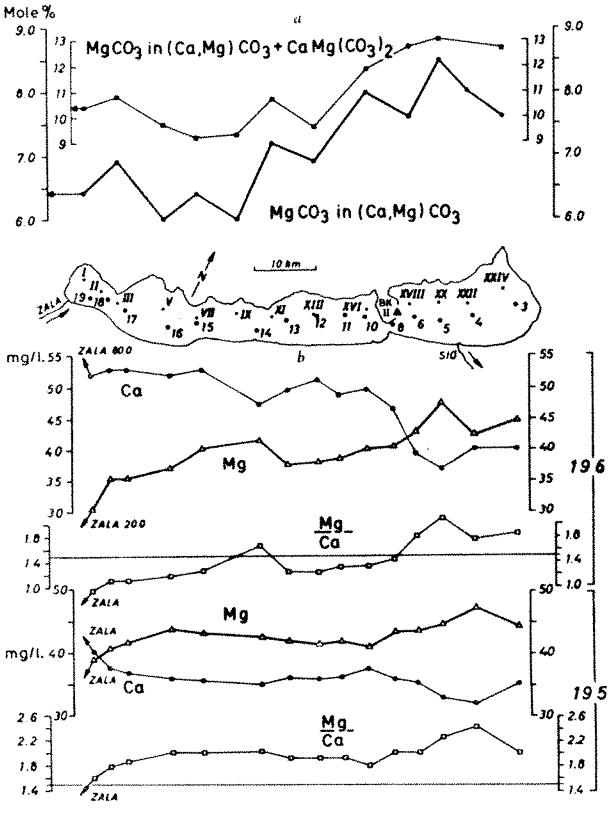

Fig. 1. *a*, $MgCO_3$ contents (in mole per cent) of high-magnesian calcites and total $MgCO_3$ concentrations of carbonates in the grain size class 2–6·3 μm (carbonates = 100 per cent) in Recent sediments of Lake Balaton (sampling stations I–XXV); *b*, Ca and Mg contents of Lake Balaton water and Mg/Ca ratios during two periods of investigation (sampling stations marked 3–19), after ref. 4. The coring station is marked "BK II".

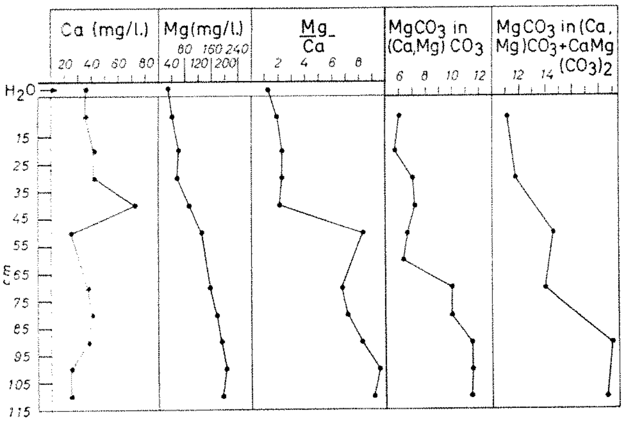

Fig. 2. Ca and Mg contents and Mg/Ca ratios of interstitial waters in sediment core "BK II" and $MgCO_3$ contents (in mole per cent) of high magnesian calcites and total carbonates in the 2–6·3 μm grain class.

greater values found (by chemical methods) come from the presence of small amounts of dolomite as well as the high-magnesian calcite derived from precipitation.

Table 1. AVERAGE COMPOSITION OF LAKE BALATON TRIBUTARIES AND LAKE BALATON WATER, AFTER REF. 2

	Inflowing water mg/l.	Lake Balaton mg/l.
K^+	5·6	6·1
Na^+	18·1	27·0
Ca^{2+}	80·6	32·0
Mg^{2+}	36·1	47·8
HCO_3^-	336·8	280·0
Cl^-	9·0	12·0
SO_4^{2-}	46·1	55·0

Recent formation of high-magnesian calcite in a fresh water environment—which to my knowledge has not yet been reported elsewhere—can be attributed here to the very large Mg/Ca ratio in comparison with other fresh water environments. It is clear from Table 1 that the average composition of the lake water differs markedly from that of the water coming to the lake (chiefly its westernmost basin) from rivers and springs. The lake water is relatively enriched in K^+, Na^+, Mg^{2+}, Cl^- and SO_4^{2-} and depleted in HCO_3^- and Ca^{2+}.

Two factors are responsible for this change in hydrochemistry. (*a*) The rate of evaporation in the lake area is higher than the rate of precipitation. According to Szesztay[3], the amount of water that leaves Lake Balaton via the Sió-canal in the eastern part of the lake is more than 25 per cent smaller than the inflow from the hinterland

$$C + H = P + L$$
$$630\text{ mm} + 860\text{ mm} = 870\text{ mm} + 620\text{ mm}$$

where C is the average annual precipitation, H the average annual inflow from the drainage area, P the average annual evaporation and L the average annual outflow via the Sió-canal. Increasing concentrations from west to east thus result. (*b*) Because of the precipitation of high-magnesian calcite caused by the photosynthesis of the phytoplankton, large amounts of Ca^{2+} and HCO_3^- (plus minor amounts of Mg^{2+}) are extracted from the lake water.

Both factors combined lead to the observed enrichment of most of the ions but to a depletion of Ca^{2+} and HCO_3^- in the lake. Fig. 1*b* shows the Ca and Mg concentrations (in mg/l.) and the Mg/Ca ratios[4] of the lake water on June 28–29, 1960, and June 23–25, 1959. From the mouth of the Zala (western part) to the eastern part of the lake the Ca^{2+} concentrations decrease but the Mg^{2+} concentrations and Mg/Ca ratios increase considerably. For the 1960 investigation the Ca and Mg curves intersect in the eastern part of the lake, whereas for 1959 the intersection point is only a few kilometres from the mouth of the Zala River. These differences are caused by annual climatic changes. The greater the inflow of river water and the amount of precipitation, the smaller are the rates of evaporation and photosynthesis and the further east is the intersection point, and vice versa. When the surface of the lake is covered by ice and photosynthesis is reduced to a minimum, there might be no intersection at all.

The general increase of the Mg/Ca ratio in the water of Lake Balaton from west to east corresponds to the observed increase of the $MgCO_3$ concentration in the precipitated high-magnesian calcite.

A 1·15 m sediment core taken near the Tihany peninsula (Fig. 1) was also studied. The results of the X-ray and chemical analyses of the sediments and interstitial waters are shown in Fig. 2.

In the interstitial waters the Mg concentrations increase with depth and the Mg/Ca ratio reaches values (9·5) that are greater than in seawater. The increase of the Mg/Ca ratio corresponds to an increase of the $MgCO_3$ incorporated in the high-magnesian calcite, which in the deepest parts of the core shows values of 11·5 mole per cent. My explanation is that the water of Lake Balaton has considerably changed its chemistry during the past thousands of years. The very large Mg/Ca ratios found in the deeper part of the core might indicate the period before the lake was first regulated by the Romans, during which an outflow existed only occasionally. This could explain the generally greater concentrations of the lake water (other ions than Mg are also enriched). The Ca content of the water, however, decreased because of the precipitation of high-magnesian calcite.

Note added in proof. In addition to the clastic dolomite (stoichiometric dolomite), which occurs mainly in the coarse silt, and sand fractions of all sediments, authigenic protodolomite (Ca_{56-58} Mg_{44-42}) has been detected in the clay fraction of most of the bottom muds. This finding resembles in many ways the formation of protodolomite in the muds of the Neusiedler Sea (Austria/Hungary)[5] in an environment with a high Mg/Ca ratio.

The Biological Research Institute of the Hungarian Academy of Sciences at Tihany kindly provided facilities for sampling.

Direct Lattice Resolution of Layer Planes in Polyacrylonitrile Based Carbon Fibres

THE microstructure of polyacrylonitrile (PAN) based carbon fibres has been investigated by several techniques including high and low angle X-ray diffraction and electron microscopy. The results obtained with high-modulus (400 GNm^{-2}) RAE carbon fibres[1,2] and high-modulus Rolls-Royce carbon fibres[3] are essentially similar; crystallites, the widths of which have a distribution of values with a mean about 65 Å, enclose sharp-edged microvoids of mean width about 10 Å. There is little three-dimensional order in the crystallites and the graphite layer planes are essentially turbostratic. The length of the crystallite seems to be limited by lattice defects to less than 100 Å although individual layers may well be much longer. Studies of rayon-based carbon fibres[4] have yielded similar evidence and recently Fourdeux, Hérinckx, Perret and Ruland[5] reported that the layer planes in these materials can be resolved directly by high-resolution electron microscopy following the phase-contrast method described by Heidenreich, Hess and Ban[6] for carbon black specimens.

Allen, Cooper and Mayer[7] have discussed the preparation of carbon fibres of exceptionally high modulus (545 GNm^{-2}) after the incorporation of boron by annealing at high temperature. One of their samples which contained a nominal 1 per cent boron after annealing at 3,000° C, and a sample annealed at 2,500° C without boron, were made available for microstructural investigation. Experience with Rolls-Royce carbon fibres suggests that microstructural differences between carbon fibres of similar strength annealed at temperatures in the range 2,500° C to 3,000° C will be negligible.

In this investigation specimens were ground and dispersed by ultrasonic irradiation in a water/ethanol mixture and then prepared on thin carbon fibres for examination in a Philips *EM*300 electron microscope with an anticontamination device. Electron diffraction observations and normal bright and dark field microscopy indicated improved orientation of the crystallites in the boron-treated specimen, a decrease in void content and an increase in crystallite size and perfection; detailed observations together with supporting X-ray diffraction evidence will be published elsewhere[8]. Direct resolution of the layer planes in both boron-free and boron-treated carbon fibre fragments was achieved by beam tilting[9] so that the zero order and {002} reflexions were symmetrical about the objective axis. After cutting off other reflexions with a 50 μm aperture and correcting astigmatism by reduction of the phase contrast background at very high magnification, through focus series were recorded with $\Delta f = 125$ Å at a magnification of × 200,000.

Fig. 1 is the optimum phase contrast image for a typical boron-free carbon fibre fragment. The layer planes (separation 3·4 Å) are discontinuous and imperfect, giving rise to (dark) extinction bands where they are distorted out of planes parallel to the incident electron beam.

Fig. 2 is the optimum image of part of a typical boron-treated carbon-fibre fragment. Recrystallization has occurred to give a more extensive and perfect lattice than is found in a normal carbon fibre. Extinction bands again mark lattice changes or defects; for example, the band BB delineates a region where the lattice tilts approximately 3°, and TT indicates a region where the lattice appears to twist giving rise to an area where the planes cannot be seen. These images provide additional information for the schematic model proposed earlier by Johnson and Tyson[3] for PAN based carbon fibres annealed at high temperatures. In addition, the suggestion that the subgrain boundaries between the crystallites are comprised of both tilt and twist components is substantiated by direct observation of the frequent layer plane discontinuities.

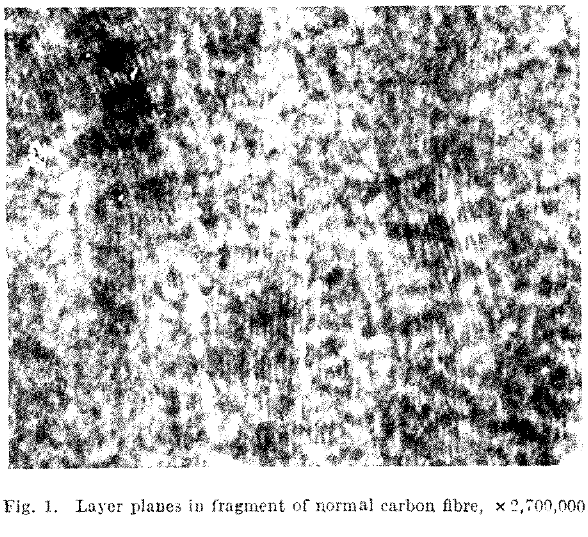

Fig. 1. Layer planes in fragment of normal carbon fibre, × 2,700,000.

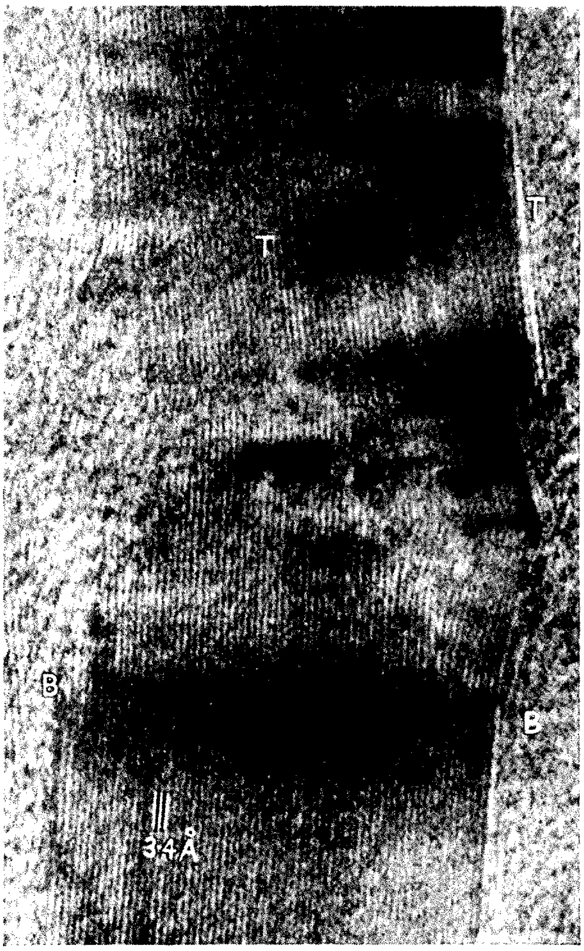

Fig. 2. Layer planes in fragment of boron-treated carbon fibre. × 2,700,000. Lattice spacing is 3·4 Å.

The increased Young's modulus and electrical conductivity reported by Allen, Cooper and Mayer[7] for boron-treated fibres can now be seen to be a result of improved orientation and perfection of the crystallites; clearly direct-lattice resolution of layer planes is a useful supplement to existing electron-microscope and X-ray diffraction methods used for microstructural investigations of carbon fibres.

I thank Dr G. Cooper of NPL and Dr R. M. Mayer, now of the South African Atomic Energy Authority and formerly of NPL, for the carbon fibre samples used in this work, and the Science Research Council for the provision of a Philips *EM*300 electron microscope in a grant to Dr J. Sikorski of this laboratory.

BIOLOGICAL SCIENCES

Is DNA Polymerase involved in DNA Degradation following Ionizing Radiation?

Exposure of microorganisms to ultraviolet or ionizing irradiation results in a partial degradation of their DNA. In most bacterial strains irradiated with ultraviolet light the depolymerization is not very extensive and is usually considered to be part of the DNA repair systems[1,2]. This process excises the mismatched regions of a DNA molecule containing pyrimidine dimers and replaces them by a new stretch of correctly paired nucleotides. The degradation of DNA in X or γ-irradiated microorganisms is more drastic[3,4], and parallels in extent both the radiosensitivity of bacterial strains and the radiosensitivity of their growth phases[5]. This suggests that in the case of ionizing irradiation DNA breakdown is not a part of the repair process. Moreover, the main lethal events in X-irradiated bacteria are probably internucleotide chain breaks in DNA[6,7] rather than the formation of mismatched regions. There is thus no need for such a drastic degradation before rejoining of the newly formed ends. The repair replication of DNA observed in ultraviolet-irradiated microorganisms has not been detected after X-irradiation[8].

The degradation of DNA caused by ultraviolet light and that caused by ionizing irradiation might be achieved by the same biochemical mechanisms. There has been no evidence as yet, however, concerning the enzyme(s) involved in the process of DNA breakdown. Studies with γ-irradiated *Escherichia coli* have shown that the degradation is catalysed by pre-existing enzyme(s)[5]. To learn more about this enzyme we have studied the type of enzymic attack on DNA in irradiated cells. ^{3}H-thymidine labelled material isolated at various times after γ-irradiation, denatured by alkali, and then chromatographed on a column of 'Sephadex *G*-200', gave rise to two peaks only: one corresponding to high molecular weight DNA and the other to very low molecular weight products[9]. We have been unable to detect any fragments of intermediate molecular weight by chromatography on 'Sepharose 2B' (unpublished results). These data indicate that an exonuclease is responsible for the degradation. Additional support for the exonucleolytic character of the degradation can be found in an early observation of Stuy[3], who observed that the rate of decrease in transforming activity equals that of decrease in the amount of DNA in X-irradiated *Haemophilus influenzae*.

Our analysis of the final breakdown products released into the medium has revealed, however, the presence of some products which would not be produced by the action of an exonuclease. An exponentially growing culture of *E. coli* K12 was labelled with ^{3}H-thymidine and irradiated with 20 kr of X-rays. After incubation for 90 min after irradiation, a sample of the medium was chromatographed on a column of 'Sephadex *G*-25' (Fig. 1). Two radioactive peaks were observed. The principal peak (peak II) contained 80 per cent of the recovered radioactivity and was identical to the peak obtained with non-radioactive thymine. The identity of this radioactive compound was confirmed by paper chromatography (Whatman 'No. 1', descending) in two solvent systems: (*a*) water; (*b*) 86 per cent butanol with 5 per cent of concentrated ammonia in the bottom of the tank. Thymine was also identified as the major breakdown product by Pollard and Achey[10]. It is probably a secondary product of degradation, produced from thymidylic acid (TMP) by the action of 5′-nucleotidase, an enzyme located at the surface of bacterial cell[11]. If this is true, some 80 per cent of all radioactive breakdown products must be formed by a typical exonucleolytic action. A smaller part of the radioactive breakdown products, however, was eluted before thymine (Fig. 1, peak I). This material is neither thymidine nor TMP; its chromatographic properties indicated that it could represent a mixture of small oligonucleotides. When this material was digested with phosphodiesterase (Fig. 2) its chromatographic behaviour on the column of 'Sephadex *G*-25' was identical with that of unlabelled TMP.

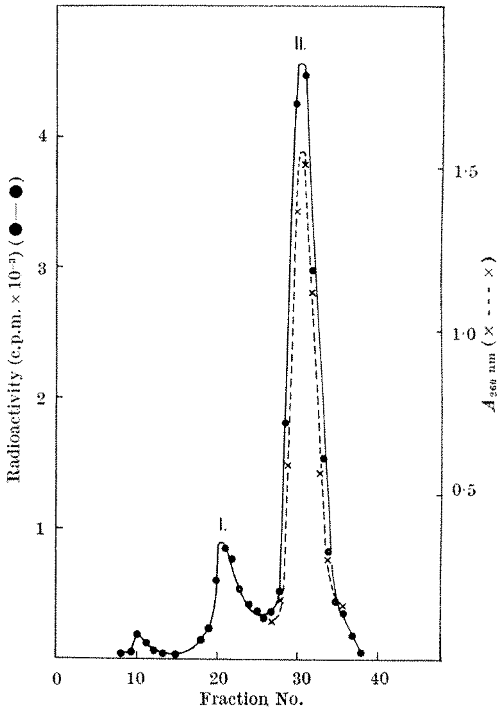

Fig. 1. Chromatography on dextran gel ('Sephadex *G*-25') of the medium containing radioactive breakdown products of DNA. 10 μCi of ^{3}H-thymidine (specific activity 3 Ci/mmole) was added to 100 ml. of a mid-logarithmic phase culture of *E. coli K*12. After 10 min the bacteria were collected, washed and resuspended in 100 ml. of fresh medium. After a further 30 min of incubation at 37° C the cells were harvested again and resuspended in 10 ml. of M/15 phosphate buffer, *p*H 7. The suspension was irradiated at 0° C with 20 kr of X-rays at a dose rate of 800 r/min. After incubation for 90 min at 37° C the bacteria were removed by centrifugation; 1 ml. of the supernatant fluid, after addition of 0·1 mg of non-radioactive thymine, was layered on the top of 31 cm × 0·87 cm² column of 'Sephadex *G*-25'. The column was eluted with 0·067 M phosphate buffer and 1 ml. fractions were collected.

The same distribution of radioactivity shown in Fig. 1 was observed when the medium was analysed 15 min after irradiation, that is, before the completion of DNA degradation in the bacterial culture. This result suggests that oligonucleotides (peak I in Fig. 1) are not intermediates in the production of the major breakdown product, thymine.

Our results demand an enzyme activity for the post-irradiation degradation of DNA which, until recently, would have been inconsistent with the mode of action of any known exonuclease of *E. coli*. Deutscher and Kornberg, however, recently described 5′→3′ exonuclease activity of DNA polymerase[12], the principal products of this hydrolysis being mononucleotides as well as oligonucleotides. Exactly the same products are formed in bacteria after ionizing irradiation, and we suggest that the hydrolytic action of DNA polymerase is responsible for their formation. The same enzyme is capable of excising the regions of DNA containing photoproducts formed by ultraviolet irradiation[13]. It has been proposed, therefore, that the polymerase plays a double part in the repair of ultraviolet-irradiated DNA: starting at a nick introduced by a specific endonuclease, this enzyme could simultaneously excise nucleotides in the 5′→3′ direction and resynthesize the degraded strand by the addition of proper nucleotides to the 3′-OH terminus formed by the nick[13]. In the case of ionizing irradiation, we must assume that the chain break, in most cases, does not produce a 3′-OH terminus; the enzyme can thus function only in the

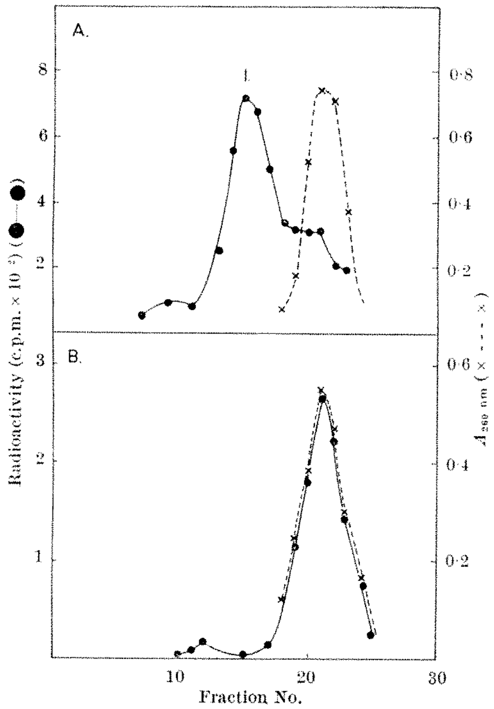

Fig. 2. Chromatography on 'Sephadex *G*-25' of the material from peak I of Fig. 1, (*A*) before and (*B*) after the digestion with phosphodiesterase. 0·1 mg of non-radioactive TMP was added to each sample. The sample (*B*) was incubated for 72 h at 37° C with an excess of phosphodiesterase from the venom of *Vipera lebetina* (a gift from Dr E. Palaček, Brno) in 0·1 M Tris-HCl (*p*H 8·5) and 0·03 M magnesium acetate. The column was eluted with 0·01 M Tris-HCl buffer (*p*H 8·5).

$5' \rightarrow 3'$ direction, as an exonuclease and not as a polymerase. Such an action would result in a final loss of viability of the irradiated cell—a phenomenon which indeed accompanies the degradation of DNA in X or γ-irradiated bacteria[5].

Conservative Mutations in Homologous Proteins

IT has been argued that most of the evolutionary changes observed in homologous proteins are the result of chance fixation of selectively neutral mutations[1,2]. This hypothesis would be clarified by a more detailed analysis of observed patterns of amino-acid substitutions in related proteins than has been attempted previously[3].

When phenylalanine, tyrosine, proline, tryptophan, methionine, leucine, isoleucine and valine are considered hydrophobic and mutations to synonymous codons are ignored, the result of undirected or random interchanges is shown in Table 1. Epstein's conclusion[3] that the code is capable of favouring mutations between amino-acids of similar physical properties is confirmed.

Table 1. PERCENTAGES OF MUTATION RESULTING IN INTERCHANGE OF SIMILAR AMINO-ACIDS

	Number of mutations observed	Percentage similar	Probability percentage similar is different from	
			Random	Code-directed
Random*		50·9		
Code-directed*				
One step		66·3	$P < 0{\cdot}001$	
Two step		59·0	$P < 0{\cdot}05$	
Closely related proteins				
One step	298	85·7	$P < 0{\cdot}001$	$P < 0{\cdot}001$
Multiple step	116	67·2	$P < 0{\cdot}001$	$P = 0{\cdot}017$
Distantly related proteins				
One step	359	81·4	$P < 0{\cdot}001$	$P = 0{\cdot}001$
Multiple step	252	56·3	$P = 0{\cdot}089$	$P = 0{\cdot}434$

* Normalized to average amino-acid composition of proteins examined for mutations.

To examine the actual requirements of proteins for a particular amino-acid composition, several groups of closely related proteins were selected from the sequence data of Dayhoff and Eck[4]. These groups consisted of all the sequenced variants of the haemoglobin α and β chains, insulin A and B, cytochrome *c* and ferredoxin. Each mutation was classified as explicable by single or multiple base changes and as being between similar or dissimilar amino-acids[5]. Very distantly related proteins were similarly considered and the groups here consisted of (1) human haemoglobin α chain: whale myoglobin: lamprey globin; (2) lysozyme: lactalbumin α; (3) trypsinogen: chymotrypsinogen; (4) *B. subtilis* Carlsberg subtilisin: subtilisin BPN′; and (5) $\lambda_{\mathrm{Sh}}:\varkappa_{\mathrm{Cum}}$ Bence-Jones proteins. Clearly, single step but not multiple step mutations have been "conservative" in the sense that they have resulted in the interchange of amino-acids with similar physical properties.

In the single step mutations examined, the incidence of transversions was approximately twice the incidence of transitions (403:221) and this is the ratio expected if mutation is independent of codon base composition. For this reason and because frequency of point mutation in several globular proteins is predictable by a Poisson distribution[1], non-random mutations cannot be invoked to explain the high observed frequency of conservative mutations or the disproportionately large number of multiple step mutations in both closely and distantly related molecules.

If it is assumed that the sequence data used in this study are an unbiased sample of all observable variants of each of the proteins in question, then the number of interchanges at any particular kind of site become a function of the mutability of the site, the likelihood that any mutation will not be lethal and the proportion of that kind of site in the molecule. As shown above, the mutability of a site is independent of codon base composition. A reasonable estimate of the proportion of non-lethal mutations, based on studies of the histidine-C locus in *Salmonella*, is 0·90 (ref. 6).

When the frequency of mutated codons is relatively low, as in closely related proteins, the frequency of multiple step mutations should approximate the square of the frequency of single step mutations after correction for lethals. In our data the frequency of single step mutations is 0·051 and that of multiple step mutations is 0·020. The expected frequency of the latter is 0·0029 or about one-seventh the observed frequency.

A simple explanation for the high frequency of multiple step mutations can be made by initially assuming that all mutations occur at "restricted" sites, requiring only a polar or a hydrophobic residue. In this case 15 per cent of the sites would be unrestricted in closely related proteins, to be consistent with the experimental data. A lower limit can be established by assuming that one-fifth of single step and all multiple step mutations occur at sites requiring no particular type of residue, that is, at unrestricted sites. In these conditions 0·6 per cent of sites are unrestricted. These limits are consistent with those of King and Jukes[1] but, because we feel that the latter figure is more nearly correct, our estimate tends to be lower.

Here the concept of selectively neutral mutation is fundamental, because the interchanges occurring at unrestricted sites seem to be almost equivalent selectively. It has been demonstrated many times since Fisher[7] that an arbitrarily small selective advantage or disadvantage may be undetectable in a single individual but quite apparent in a sufficiently large population. In this context, any mutation will be considered other than neutral when a sufficiently sophisticated examination of its effects is made. It is not yet possible to assess the neutrality of such mutations at a population level[6]. It is certainly not valid to maintain that a mutated protein is equivalent to the wild type on the basis of such gross evaluation as enzyme activity assays or the absence of clinical symptoms.

Furthermore, with the exception of the haemoglobin variants, all of the proteins used in this study are the most common alleles present in a particular species, so that one cannot assume that any other sequences would be functionally equivalent. That homologous sequences are functional is not strictly relevant because the two molecules are very likely to function in quite different internal environments and many compensatory mutations may have occurred even within the same molecule.

The data presented suggest that most single step mutations fixed during specification are conservative in that interchanges are observed between amino-acids of similar physical properties. While about 65 per cent of all positions must be occupied by either a hydrophobic or polar residue, between 0·6 per cent and 15 per cent of the mutable sites may not require a polar or hydrophobic amino-acid in a protein which is functional in some circumstances. Mutations occurring at these sites are not shown to be selectively neutral, and although their selective effect may be small it is not likely to be insignificant at a population level. These data should therefore not be used to support the concept of selectively neutral mutation.

Pre-cell Evolution and the Origin of Enzymes

SALISBURY[1] has asked how enzymes could arise by natural selection from less developed ancestors if the minimal structural requirements for their activity are so inflexible that variants below a certain high level of development cannot exist. This problem can be resolved by considering the evolution of catalytic rates.

Koshland and Neet[2] have estimated that typical enzymes of present-day cells catalyse reactions at rates 10^{14} to 10^{18} times those which might be expected without a catalyst. I assume that these great activities were achieved in gradual steps, largely during the period of chemical evolution before cells existed. It would then seem reasonable that an enzyme which multiplies the rate of a particular reaction by a factor of 10^{14} may have originated as a polypeptide with a corresponding catalytic factor for the same reaction of about 10^3. If a mole of this enzyme now produces one mole of product in 10^{-2} s, it would originally have produced one mole in about thirty years. An inescapable implication of this calculation is that the earliest enzymes had catalytic activities far below the lowest levels of detection by known techniques. It is further implied that the first self-replicating pre-cell structures reproduced with extreme slowness, perhaps only once in hundreds or even thousands of years.

I now assume that speed and specificity are intimately linked in their evolution, for high rates are undoubtedly attained by close fitting of polypeptides to particular substrates. I thus propose that the first generation of enzymes consisted of random polypeptides, each of which could catalyse many reactions at extremely low rates, and that they gave rise through natural selection to individual types which were progressively more specific and faster acting. These considerations suggest a very simple first self-replicating unit, which may have formed and evolved according to the hypothetical series of events outlined in the model described below.

In the beginning millions of molecules of pre-existing random polynucleotide-like substances are slowly replicated[3,4] with the non-specific catalytic aid of pre-existing polypeptide-like polymers[5]. Through a stereochemical coding mechanism[6–10], so far undemonstrated, and polypeptide catalysis, new peptides are also formed on the polynucleotide templates. Among the original templates, I assume that one codes for a polypeptide with "nucleic acid polymerase" activity which, though still extremely small by present standards, is about ten times greater than that of the product of any other template of the period. Because of the proximity of this polynucleotide and its daughter polynucleotides to molecules of the new polymerase, further copies of the template will be made at an accelerated rate and it will therefore increase in number relative to all others. I now suppose that, associated with one of the numerous members of later generations of this polynucleotide, a new sequence of nucleotide residues occurs which codes for a polypeptide with "protein polymerase" activity greater than usual for that time, though also still very small. Clearly the two polymerase templates, functionally united with their polypeptide products, would constitute a self-replicating unit that could increase in number logarithmically in an adequate medium and far outstrip its competitors. Through step-by-step repetition of mutation and selection the two enzymes would become more rapid in action and more specific. Other enzymes, as well as structural proteins which facilitate reproduction, would be developed similarly.

An important aspect of this scheme is that the stability of the complexes formed during the first template-directed syntheses of proteins and nucleic acids may have obviated the requirement for activation of the substrates when the process was very slow. Another point is that the mutation rate should have been very great at first, diminishing as the enzymes were perfected and the accuracy of transcription was correspondingly increased.

The possibility that processes now completed in milliseconds once required hundreds of years suggests that the dominant driving force of pre-cell evolution was the demand for ever-increasing rates of multiplication to ensure survival, in contrast to the demand for adaptation which characterizes the Darwinian period. Awareness of the extreme slowness of the first developmental steps could simplify conceptual problems, but it casts a somewhat discouraging shadow on prospects for understanding these early events through laboratory experiments of the kind now in progress. A similar and related slowness seems to frustrate efforts to elucidate the separate functions of the individual parts of fully developed enzymes[11].

Enhanced Binding of FAD to Glutathione Reductase in G6PD Deficiency

THE activity of glutathione reductase (GR) in erythrocytes deficient in glucose-6-phosphate dehydrogenase (G6PD) is approximately 1·5 to 2 times higher than in red cells with normal G6PD activity[1]. This may provide a compensatory mechanism for the defect in glutathione reduction in G6PD deficient cells. The cause of the increased activity of GR in G6PD deficiency is unknown and the possibility of increased production of GR in erythrocyte precursors of G6PD deficient individuals seems unlikely. The lower mean red cell age, resulting from a moderately shortened life span of G6PD deficient erythrocytes[2], may play a part but is unlikely to account entirely for the marked increase in GR activity. Recently Beutler[3] reported a stimulation of erythrocyte GR in normal subjects by flavin-adenine dinucleotide (FAD) *in vitro* and by supplementation of its precursor riboflavin *in vivo*. GR activity was shown to depend on dietary intake of riboflavin, but even in persons with a relatively high intake of this vitamin GR does not seem to be saturated with FAD[4]. These findings suggest that differences of FAD binding of GR may provide an explanation for the increased GR activity in G6PD deficient red cells.

We have recently examined GR activity in haemolysates of three groups of subjects with normal and deficient G6PD without and with addition of FAD to the test mixture (final concentration 1·2 μM) and before and after riboflavin supplementation (10 mg per day for 8 days). The GR assay mixture contained 50 mM Tris buffer (*p*H 7·5), 0·3 mM NADPH, and 3 mM GSSG; the reaction temperature was 25° C; units correspond to a substrate turnover of 1 μmole/l. per min and 10^{11} erythrocytes. The three groups of subjects are (1) seven Europeans living in northern Thailand, (2) twelve healthy adult Thai males with normal erythrocyte G6PD activity, and (3) ten Thai males with G6PD deficiency who live in the same environmental (in particular nutritional) conditions as group (2). All individuals in group (3) had G6PD activities of less than 10 per cent of the average level of Thai males with normal G6PD activity; they were not anaemic and numbers of reticulocytes were only slightly increased (1·8 to 3·2 per cent). In the Europeans GR activity was 10·6 ± 1·8 units, a value similar to that observed in a large group from Germany[5]. The results in the Thai groups are shown in Table 1.

Table 1. GR IN ERYTHROCYTES OF SUBJECTS WITH NORMAL AND DEFICIENT G6PD. EFFECT OF ADDITION OF FAD AND SUPPLEMENTATION OF RIBOFLAVIN

Group	GR activity before riboflavin supplementation		
	Without FAD	FAD added	Increase with FAD (per cent)
G6PD normal	8·9 ± 2·1	14·8 ± 1·8	66·8 (25·8–133·3)
G6PD deficient	15·8 ± 2·2	16·6 ± 1·9	5·7 (0–12·1)
	GR activity after riboflavin supplementation		
	Without FAD	FAD added	Increase with FAD (per cent)
G6PD normal	15·1 ± 2·1	15·6 ± 1·8	3·6 (0–10·5)
G6PD deficient	16·6 ± 1·8	17·0 ± 1·7	2·3 (0–6·7)

In the group with normal G6PD activity the mean level of GR activity is lower than that in Europeans, possibly reflecting a lower dietary supply of riboflavin. Addition of FAD to the test mixture results in a considerable increase in GR activity (average 67 per cent). After administration of riboflavin, GR activity without added FAD is similar to that originally observed with added FAD, and the rise caused by addition of FAD is now minimal. In the group with G6PD deficiency original GR activity is, on the average, 78 per cent higher than in the group with normal G6PD. Addition of FAD and riboflavin supplementation result in only a small increase in GR activity.

The results indicate that FAD binding of GR is much closer to saturation in erythrocytes of subjects with G6PD deficiency living in the same environmental conditions as a control group with normal G6PD. Although maximal GR activity after supplementation of riboflavin and addition of FAD is lower in the group with normal G6PD (15·6 compared with 17·0 units), the probability for a chance difference is relatively high ($0\cdot1 > P > 0\cdot05$). This suggests that increased binding of FAD by GR accounts for most of the elevation of GR activity in G6PD deficient erythrocytes in normal nutritional conditions. If a significant difference of maximally stimulated GR activity between subjects with normal and deficient G6PD emerges from a larger sample, this relatively small additional increase would be most likely attributable to the younger red cell population in G6PD deficiency. Increased absorption of riboflavin by G6PD deficient individuals or a stuctural difference of GR in erythrocytes with normal and deficient G6PD seem improbable. Thus it seems likely that the metabolic anomalies of G6PD deficient red blood cells cause an elevation of FAD concentration or facilitate the binding of FAD by the GR enzyme.

Hybrid Molecules of Yeast and Rabbit GPD containing Native and Modified Subunits

CONVINCING evidence has been presented that molecules of glyceraldehyde-3-phosphate dehydrogenase (GPD) from yeast[1] and from rabbit skeletal muscle[2] each comprise four identical polypeptide chains and bind a maximum of four molecules of NAD per molecule of enzyme[3–5]. But whereas the binding of NAD to the yeast enzyme (Y_4) at 40° C is considered[3,4] to conform to the Monod, Wyman and Changeux model[6] for allosteric interactions, which requires highly cooperative structural transitions of the subunits within a given enzyme molecule, the binding of NAD to rabbit GPD (R_4) shows a negative cooperativity in that binding of successive molecules of NAD to a given GPD molecule diminishes the affinity for NAD of the remaining unoccupied sites[5]. As such the rabbit enzyme conforms to the "stepwise" model for ligand binding proposed by Koshland, Nemethy and Filmer[7].

Because the differences in behaviour of NAD binding presumably reflect differences in interchain interactions in the yeast and rabbit enzymes we were interested to attempt the preparation of hybrid molecules of GPD comprising subunits from both enzymes. We describe here the preparation of such hybrids as well as of hybrids in which two of the four subunits are covalently substituted at the active centre with 2-bromoacetamido-4-nitrophenol[8] (Koshland's "reporter" group).

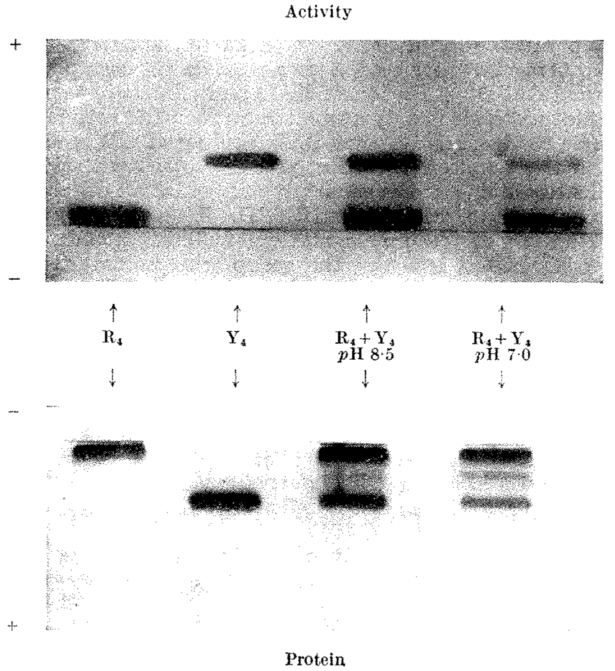

Fig. 1. Starch-gel electrophoresis of a hybridized mixture of yeast and rabbit GPD. Solutions containing both yeast (Y_4) and rabbit (R_4) GPD at a concentration of 3 mg/ml. were dialysed at *p*H 7·0 or 8·7 in the conditions described in the text. Electrophoresis was carried out for 4 h at 30 V/cm using the system of Rosemeyer and Huehns[15]. The upper photograph shows one half of the gel stained for enzyme activity and the lower photograph the other half stained for protein. Enzymically active bands in the position expected for the R_2Y_2 hybrid are obtained after hybridization at both *p*H values.

Fig. 1 depicts the results of starch gel electrophoresis of mixtures of yeast and rabbit GPD (each containing approximately four molecules of bound NAD per enzyme molecule), previously dialysed for 14 h at 4° C against either 0·01 M citrate–0·001 EDTA at *p*H 7 or 0·01 M Tris-0·005 M borate–2×10^{-4} M EDTA at *p*H 8·7, the latter buffer being that used in the electrophoresis. In each case an additional enzymically active band is observable with a relative migration of 0·54 compared with a value of 1·00 for the yeast enzyme (Y_4) and 0·16 for the rabbit enzyme (R_4). The relative migration of R_3Y, R_2Y_2 and RY_3 hybrids would be 0·79, 0·58 and 0·37, respectively, given that the size and shape of the yeast and rabbit enzymes are identical and differ only in charge, so that the single new band with a relative migration of 0·54 is identifiable as the R_2Y_2 hybrid. Note that bands in the positions expected for RY_3 or R_3Y hybrids have not been observed in the course of more than sixteen hybridization experiments covering a range of protein concentrations from 1·0 to 4·0 mg/ml.

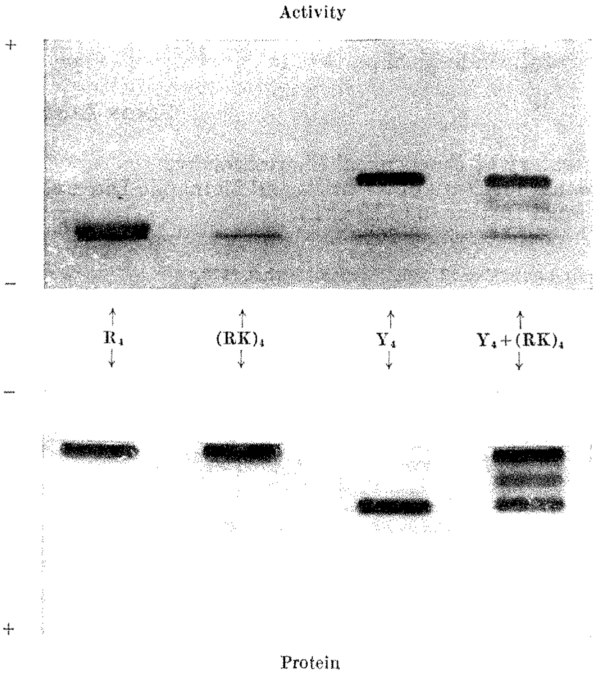

Fig. 2. Starch-gel electrophoresis of a hybridized mixture of yeast and modified rabbit GPD. The conditions were as for Fig. 1 except that the yeast GPD (Y_4) was hybridized with rabbit GPD modified by reaction with Koshland's reagent, $(RK)_4$. The $(RK)_4$ derivative is shown to be enzymically inactive but the $(RK)_2Y_2$ band is clearly active.

The ability to make R_2Y_2 hybrids allows in principle the preparation of hybrids in which two subunits have been covalently substituted. Thus yeast GPD (Y_4) was hybridized with rabbit GPD which had been previously inactivated by substitution with Koshland's reagent[8] at four sites per tetramer [$(RK)_4$] (ref. 9). This derivative has been shown to be modified at the four "rapidly reacting" thiol groups of GPD (refs. 9 and 10). After hybridization a single new species (Fig. 2) was again observed with a relative migration value of 0·59 ($Y_4=$ 1·00). Furthermore, this hybrid was enzymically active with G3P as substrate, indicating that yeast chains are catalytically active even when combined with inactive rabbit chains. As in the case of the Y_4+R_4 hybridizations, only one type of hybrid was observed, migrating in a position near that expected for a $(RK)_2Y_2$ hybrid.

In a separate experiment, the $(RK)_2Y_2$ hybrid was rapidly eluted from the starch gel and assayed with glyceraldehyde 3-phosphate as substrate before reversion to $(RK)_4$ and Y_4 occurred. It was found that the $(RK)_2Y_2$ hybrid had a specific activity of 45 per cent of the native yeast enzyme, indicating that combination with the inactive rabbit chains has little effect on the catalytic activity of the yeast subunits.

The failure to observe RY_3 and R_3Y hybrids in the conditions of this study indicates that the molecules of yeast and rabbit GPD must be regarded as isologous[6] rather than heterologous[6] tetramers (see Fig. 3). This conclusion is consistent with: (*a*) the finding that the molecules of lobster[11] and human[12] GPD have two-fold

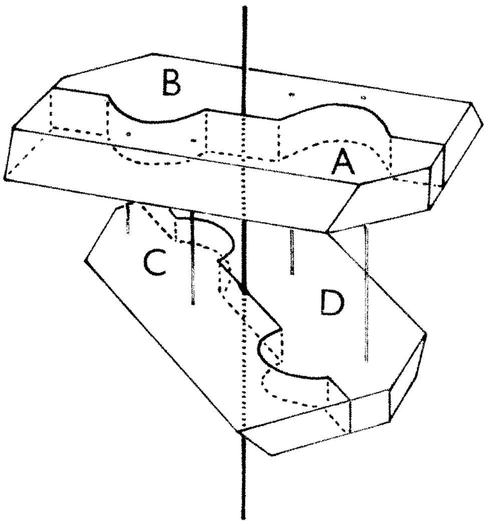

Fig. 3. Diagrammatic representation of an "isologous" tetramer comprising four identical subunits. The structure has three mutually perpendicular two-fold axes of rotation, one being shown as the dark vertical line. The A–B, A–C and A–D interactions are non-equivalent.

symmetry axes, (*b*) the fact that the rabbit muscle enzyme dissociates to dimers on dilution[13], and (*c*) the observation that only two equivalents of furylacryloyl groups could be introduced per molecule of rabbit or yeast GPD (ref. 14).

The formation of hybrid molecules from enzymes taken from such widely differing organisms as yeast and the rabbit indicates that the nature of the (AB)–(CD) interaction must be similar in each enzyme (see Fig. 3). But it seems that this interaction, although similar, is probably not identical, for in that case it would be anticipated that an equilibrium mixture formed from equal amounts of rabbit and yeast GPD would contain R_4, R_2Y_2 and Y_4 in the ratio 1 : 2 : 1. Inspection of Figs. 1 and 2 shows that such a ratio is not attained, indicating either that equilibrium had not been reached in these experiments or that the inter-dimer interaction of R_2 with Y_2 in R_2Y_2 is weaker than that of one or both of the (R_2)–(R_2) or (Y_2)–(Y_2) interactions in R_4 or Y_4. We now seek to determine the kinetic and thermodynamic aspects of hybrid formation as well as the chemical properties of the native and modified hybrid.

Lymphocyte Activation: a Rapid Test to predict Allograft Rejection

THE early detection of allograft rejection, before organ function deteriorates, is an important objective of clinical research in transplantation immunology. Because lymphocytes play a central part in graft rejection[1,2], attention was focused on these cells in the circulation of graft recipients. We observed that the numbers of circulating lymphocytes that incorporate ^{3}H-thymidine rise significantly during organ allograft rejection and may predict rejection crises by 24–48 h.

The ^{3}H-thymidine incorporation of the circulating lymphocytes of organ allograft recipients was studied serially. Peripheral blood was collected by venipuncture, defibrinated by swirling with glass beads and the red blood cells sedimented with 0·4 per cent dextran. The resultant leucocyte rich serum was adjusted with the patient's own cell-free serum to a final concentration of 10^6 lymphocytes per ml. 1 ml. of this cell suspension and 2 ml. tissue culture media were incubated in quadruplicate in 13×100 ml. round bottom tubes in a water bath at 37° C for 30 min. 2 μCi of ^{3}H-thymidine was then added and the tubes incubated for a further 2 h. The cells were then washed, treated with 10 per cent trichloroacetic acid and the acid-precipitable radioactivity counted in a liquid scintillation counter. Results were recorded as the average counts per minute per 10^6 lymphocytes (c.p.m.) of the four samples.

Table 1. CORRELATION BETWEEN ACTIVATED LYMPHOCYTES AND CLINICAL DATA

Days after graft	24 h urine output (ml.)	Serum creatinine (mg per cent)	Azathioprine (mg/d)	Methyl prednisolone (mg/d)	ALG (mg/d)	Activated lymphocytes c.p.m./10^6 lymphs
0	1,038	9·2	350	125	0	102
1	1,842	7·2	200	120	0	N.D.
2	2,829	2·3	250	80	0	N.D.

6	30	5·0	200	200	75	2,107
7	120	7·5	200	240	150	1,027
8	65	12·4	200	200	300	2,038
9	633	11·7	200	240	300	N.D.
10	1,184	13·8	200	240	350	2,422
11	1,490	7·8	200	240	350	780
12	2,405	N.D.	200	160	350	980

Fifteen normal subjects served as controls. The ^{3}H-thymidine of their circulating lymphocytes was low (median: 270 c.p.m.; range: 92–1,420 c.p.m.).

Nine potential allograft recipients were studied before transplantation. The thymidine incorporation of their circulating lymphocytes was also low (median: 225 c.p.m.; range: 47–859 c.p.m.).

The nine patients subsequently received an organ allograft, seven renal and two cardiac. Serial studies after transplantation revealed that, in six of the subjects, the ^{3}H-thymidine incorporation of their circulating lymphocytes rose to over 2,000 c.p.m. per 10^6 lymphocytes. The median of the six was 4,100 c.p.m. with a range of 2,100–15,000 c.p.m. Each rise occurred during the three week period after the transplant, was correlated with an episode of graft rejection and usually preceded clinical evidence of graft rejection by 24–48 h. A representative case is shown in Table 1. When the data were corrected so that the results were expressed as c.p.m. per total circulating lymphocyte population, the rise was still seen. Even though the patients usually became very lymphopenic after transplantation, there was thus a 6·2 to 7·8-fold increase in the absolute number of circulating thymidine incorporating cells. In three patients an attempt to reverse rejection by increasing the dosage of immunosuppressive therapy was associated with a prompt fall in the ^{3}H-thymidine incorporation of the patients' circulating lymphocytes.

The appearance of ^{3}H-thymidine incorporating large lymphoblasts has been observed in nodes draining the graft bed before graft rejection in animals[1]. The appearance of these cells heralds the development of immunological commitment to the graft antigens. During effective immunosuppression the development of committed effector lymphocytes from these cells is inhibited[2]. During the immune response to antigenic stimuli, including grafts, large numbers of these large lymphoid cells are produced by proliferation, are released into the efferent lymph, enter the blood and ultimately invade the graft bed where they act as effectors of cellular immunity[3]. This phenomenon also occurs during the response of man to typhoid vaccine and the cells can be detected in the peripheral blood by morphological examination or by measurement of thymidine incorporation[4].

On the basis of these findings, we postulated that the activated lymphocytes would appear in the circulation and could be detected during or even preceding clinical evidence of graft rejection. The experimental data support this hypothesis and suggest that the serial measurement of peripheral blood activated lymphocytes will provide data which can predict by 24–48 h an episode of organ allograft rejection.

Blood Group H Antigen of Influenza A2 Virus

McDonald and Zuckerman[1] have demonstrated statistically that there are a large number of blood group O patients and a relatively few of group A among those infected with influenza A2 virus. Subsequent studies[2–4] have indicated, however, that an antibody against influenza was more commonly found in sera of group O persons than group A. Potter and Schild[2] suggested that such a divergency in influenza infection was influenced by genetic factors related to ABO blood groups. We have examined influenza viruses for blood group antigens in order to obtain evidence for any possible relationship between influenza and ABO blood groups.

We used allantoic fluid from hens' eggs inoculated with influenza A, A2 or B virus. The fluid was centrifuged at low speed to remove membrane debris and centrifuged for a further 3 h at 100,000*g* to sediment viruses; the sediment was washed by resuspending it in buffered saline (*p*H 7·0) and then centrifuging. The final sediment was suspended homogeneously in buffered saline, and its agglutinating titre with chicken red cells adjusted to 1 : 2,048 by dilution. The suspension was heated for 20 min in boiling water. Preliminary tests of agglutinin inhibition showed no decrease in titre of anti-A, anti-B and anti-H agglutinins. The suspension was then examined by an absorption–elution test in the following way. Thin pieces of paper (3 × 5 mm) were dipped into a serially diluted row of the suspension, containing 2·5 per cent hen's egg albumin, and dried at room temperature. The papers were immersed in acidified methanol for 20 min and dried for 4 h at 56° C; they were then placed in 1 ml. of potent anti-H reagent (extract of *Ulex europaeus* seed) and allowed to stand overnight at 2° C, after which time they were washed four times in a sufficient volume of normal saline. After the addition of normal saline (0·09 ml.) the papers were heated at 50° C for 20 min in a water bath. Eluted agglutinin in the normal saline was separated and a serial dilution was made immediately.

Table 1. COMPARISON OF RESULTS OF ANTI-H ABSORPTION–ELUTION TESTS OF INFLUENZA A, A2 AND B VIRUSES

Virus	Titres of anti-H obtained by tests of undiluted samples	Minimum virus* concentrations to detect anti-H
Influenza A	< 1	> 2,048
Influenza A2 (Kumamoto)	8	64
Influenza A2 (Hongkong)	8	128
Influenza B	1	2,048
Control	< 1	—

* Represented by titres of chicken red cell agglutination.

Agglutinin tests of the eluate were performed by the immediate addition of a 1/2 part of 0·5 per cent red cell suspension (group O) to the diluted row and by low speed centrifugation after addition of 1/2 part of agglutinin-free human group AB serum following 15 min storage at 5° C. Tests of papers adsorbing the undiluted suspension of influenza A2 viruses gave relatively high titres of anti-H activity (Table 1); the influenza A virus proved to have a trace of anti-H in an eluate; the B virus gave a weakly positive reaction. The minimum concentrations of the viruses required for the detection of anti-H were low for A2 viruses and high for A and B. A control experiment was simultaneously performed using paper adsorbing non-inoculated egg allantoic fluid plus 2·5 per cent egg albumin, but the results of absorption–elution were negative. Detection of blood group A and B antigens was also performed, but the results obtained were not reliable, because in some experiments anti-A and anti-B were eluted from papers with fixed egg albumin only.

Our results establish the presence of blood group H antigen in influenza A2 and B viruses, the quantity being more in A2 than in B. We conclude that anti-H agglutinin is involved in the prevention of certain influenza infections. The relatively high incidence of group O patients infected with some types of influenza may be attributable to the lack of anti-H antibody in their sera or secretions.

Relationship between Glutathione Reductase Activity and Drug-induced Haemolytic Anaemia

THE maintenance of glutathione in the reduced state in red cells is achieved through the following three metabolic steps

$$\text{Glucose} + \text{ATP} \xrightarrow{\text{hexokinase}} \text{glucose 6-phosphate} + \text{ADP} \qquad (1)$$

$$\text{Glucose 6-phosphate} + \text{NADP} \xrightarrow[\text{dehydrogenase}]{\text{glucose 6-phosphate}} \text{glucono-}\delta\text{-lactone 6-phosphate} + \text{NADPH} \qquad (2)$$

$$\text{GSSG} + \text{NADPH} \xrightarrow[\text{reductase}]{\text{glutathione}} 2\ \text{GSH} + \text{NADP} \qquad (3)$$

In glucose 6-phosphate dehydrogenase deficiency, metabolism in the second step of the sequence is impaired. As a consequence, when treated with acetylphenylhydrazine *in vitro*, the red cells form increased numbers of Heinz bodies[1] and show instability of GSH. *In vivo*, they are susceptible to haemolysis by drugs such as primaquine, nitrofurantoin, phenylhydrazine and sulphonamides[3].

The consequences of a defect in the third step of this sequence, catalysed by glutathione reductase, are not yet clear. It has been held that glutathione reductase deficiency, like glucose 6-phosphate dehydrogenase deficiency, results in increased susceptibility to the haemolytic effects of oxidative drugs[4-7]. But because the level of glutathione reductase in such patients is only decreased to about one-half of the normal value, the aetiological role of glutathione reductase deficiency in the haemolytic episodes reported has been questioned[8].

It has been found recently that red cell glutathione reductase activity depends largely on dietary riboflavin intake[9-11]. Deficiency of this enzyme can be corrected within a few days by the oral administration of only 5 mg riboflavin[11] or 10 mg flavin mononucleotide daily[12]. This has made it possible for us to examine the role of glutathione reductase deficiency in the origin of drug-induced haemolytic anaemia.

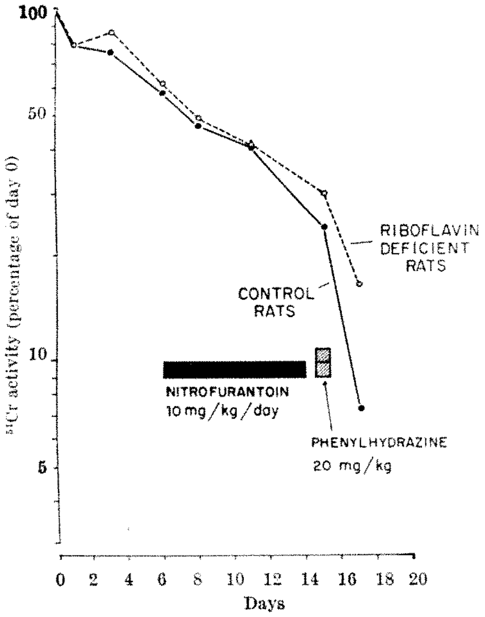

Fig. 1. The effect of nitrofurantoin and phenylhydrazine on the survival of ^{51}Cr labelled erythrocytes in glutathione reductase deficient (riboflavin deficient) and control rats. The points represent average values obtained from four riboflavin deficient and two control rats.

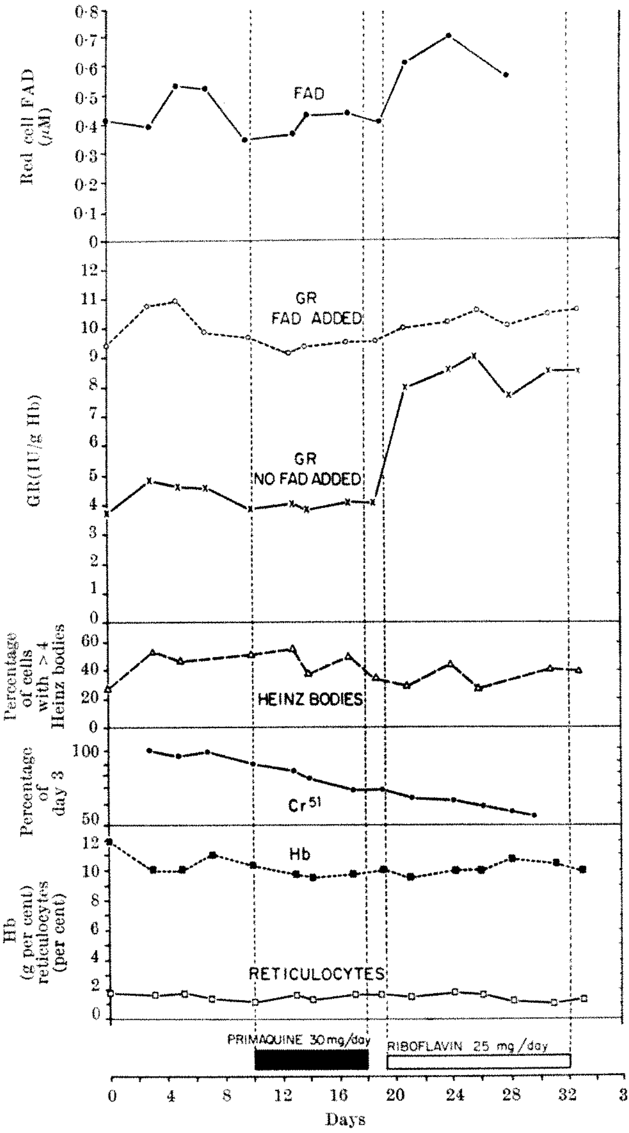

Fig. 2. The effect of primaquine and riboflavin on the erythrocyte of glutathione reductase (GR) deficient (riboflavin deficient) subject.

Preliminary studies were carried out on four rats on a riboflavin-free diet (Nutritional Biochemicals). After 5 weeks, glutathione reductase levels in the red cells of the riboflavin deficient rats were found to average 1·8 international units/g haemoglobin at 37° C, which was 31 per cent of the level in the red cells of rats on the same diet supplemented with 20 mg of riboflavin/kg of diet. Glutathione reductase assays were carried out as previously described[10]. ^{51}Cr survival curves were carried out before and during the administration of 10 mg nitrofurantoin per kg of body weight daily for 8 days. No change in the ^{51}Cr red cell survival curve was found (Fig. 1). Each rat was then given a single dose of 20 mg phenylhydrazine-HCl per kg body weight subcutaneously. The fall in ^{51}Cr activity of the blood indicated that this dose produced rapid red cell destruction, but the rate of red cell destruction was no greater in riboflavin deficient than in normal animals.

We then studied a Negro female (N.L.-2) with sickle cell trait and very mild iron deficiency anaemia. She has been known to have red cell glutathione reductase levels diminished to approximately 60 per cent of normal for several years[11]. She was given a diet containing between 0·5 and 0·6 mg of riboflavin daily, and a ^{51}Cr red cell survival study was initiated. There was no change in the slope of the ^{51}Cr survival curve when 30 mg of primaquine base was given daily for 8 days. The patient was then given 25 mg of riboflavin daily, and a rise in her red cell glutathione reductase activity and flavin adenine dinucleotide (FAD) levels was noted. There was no change, however, in ^{51}Cr survival, haemoglobin level, reticulocyte count or Heinz body test[1] (Fig. 2).

Our findings show that if levels of glutathione reductase are decreased to 40–60 per cent of normal, sensitivity to the haemolytic anaemia induced by oxidant compounds does not ensue. Either the glutathione reductase activity as measured in the haemolysate does not represent the *in vivo* capacity of the red cell to reduce GSSG, or, more likely, the glutathione reductase activity does not represent the limiting step in the sequence of reactions 1–3 which are required. We assume that in those patients reported to have drug-induced haemolytic anaemia with glutathione reductase activities 50 per cent of normal, factors other than the glutathione reductase level must have been important in the aetiology of the haemolytic anaemia.

Lanthanum Inhibition of ^{45}Ca Efflux from the Squid Giant Axon

LETTVIN *et al.*[1] predicted that lanthanum ions, because of their relatively small size and high charge density, should have a much greater electrostatic attraction for any negative calcium binding site than calcium ions themselves. This was borne out for the membranes of the barnacle muscle fibres[2] and the lobster axon[3]. If negatively charged sites located in the membrane also serve to transport calcium ions across it, then lanthanum ions would be expected to displace calcium from these sites, and thereby inhibit the calcium ion flux. It has been shown that this is true for an artificial membrane with negative groups of phospholipids lining aqueous pores[4]. Data obtained by Weiss and Goodman[5] and Van Breemen[6] indicate that lanthanum ions also block the calcium transport across smooth muscle membranes. In smooth muscle physiology there is much uncertainty about the relative contribution of calcium influx to the initiation of contraction, and a calcium transport blocking agent would be very useful. In addition, information regarding the nature of the lanthanum blockade should contribute to the understanding of the cell membrane calcium transport system itself.

Baker *et al.*[7] demonstrated that lanthanum inhibited the lithium-sensitive sodium efflux which is coupled to calcium influx. Blaustein and Hodgkin[8] have shown that part of the calcium efflux from the squid axon is coupled to calcium influx and part to sodium influx. Evidence for calcium exchange diffusion has also been presented for smooth[9], cardiac[10] and skeletal[11] muscle, and a phospholipid-cholesterol membrane model[4]. We have sought more direct evidence on lanthanum blocking of cell membrane calcium transport, and hoped in so doing to obtain additional information regarding calcium transport in general.

A solution (0·3 µl.) of ^{45}Ca, 0·5 mCi/ml. in 0·5 M KCl, was injected into squid axon longitudinally according to the method of Caldwell *et al.*[12]. The final concentration of the added calcium in the axoplasm was 0·3–0·5 mM. After the injection, the chamber in which the axon was suspended was reduced to 1 ml. and perfused with the experimental solutions at the rate of 0·8 ml./min. The perfusion solutions were collected every 3 min, dissolved in Bray's scintillation fluid, and counted in a Packard liquid scintillation counter. The axon was exposed to 1 M HCl at the end of the experiment, and counted in Bray's scintillation fluid after neutralization and addition of an equal aliquot of seawater. The external perfusion solution was: 425 mM NaCl, 10 mM KCl; 50 mM $MgCl_2$, 10 mM $CaCl_2$, 0·1 mM EDTA and 2 mM Tris (pH 7·8). In the calcium free solutions, $CaCl_2$ was replaced by $MgCl_2$.

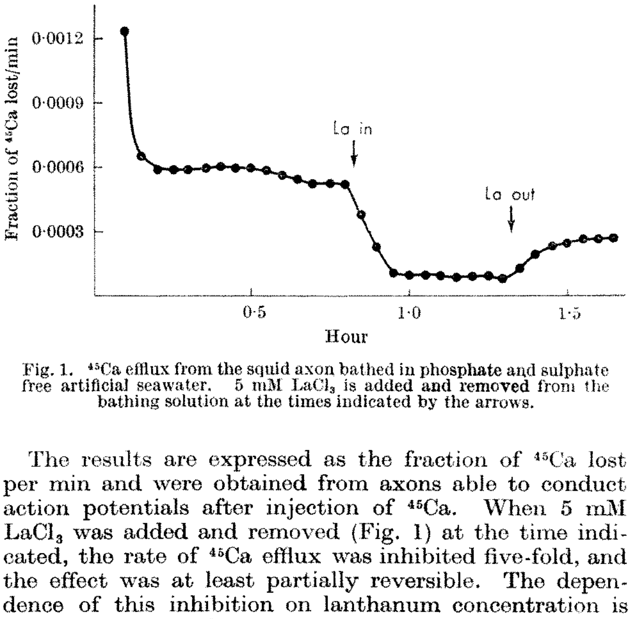

Fig. 1. ^{45}Ca efflux from the squid axon bathed in phosphate and sulphate free artificial seawater. 5 mM $LaCl_3$ is added and removed from the bathing solution at the times indicated by the arrows.

The results are expressed as the fraction of ^{45}Ca lost per min and were obtained from axons able to conduct action potentials after injection of ^{45}Ca. When 5 mM $LaCl_3$ was added and removed (Fig. 1) at the time indicated, the rate of ^{45}Ca efflux was inhibited five-fold, and the effect was at least partially reversible. The dependence of this inhibition on lanthanum concentration is shown in Fig. 2 and these results can be plotted according to the equation

$$\text{inhibition}/\text{inhibition}_{\max} = (\text{La})^e/[(\text{La})^e + K_D]$$

where $K_D = 0{\cdot}23$ mM and the maximum inhibition is 87 per cent.

Thus, in the presence of 10 mM external calcium, the half saturation value for the inhibition of calcium efflux by lanthanum is 0·23 mM. Removal of external calcium reduced this value to about 0·1 mM.

Lanthanum at a concentration of 5 mM rendered the axon inexcitable, after the action potentials first became of long duration and low amplitude. Only 0·1 mM $LaCl_3$ was sufficient to abolish spontaneous firing of the axon in calcium and magnesium free seawater and restore normal excitability.

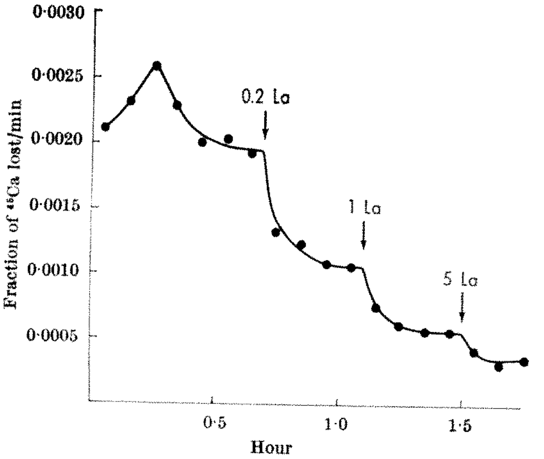

Fig. 2. ^{45}Ca efflux from the squid axon in the absence of LaCl$_3$ and presence of 0·2 mM, 1 mM and 5 mM LaCl$_3$. Concentrations of LaCl$_3$ are changed at the times indicated by the arrows.

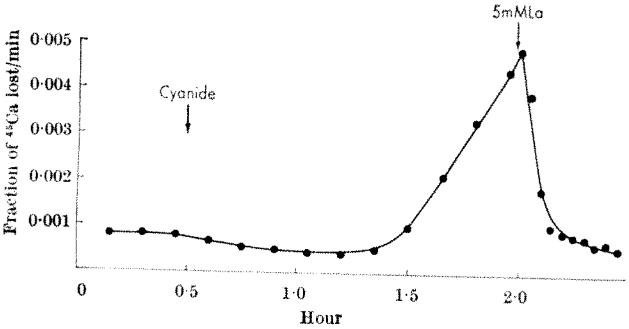

Fig. 3. ^{45}Ca efflux from the squid axon. At the first arrow 2 mM cyanide is included in the bathing solution. At the second arrow 5 mM LaCl$_3$ is also added.

Fig. 3 confirms the increase in ^{45}Ca efflux following 2 mM cyanide reported by Blaustein and Hodgkin[8], and shows, in addition, that this increased ^{45}Ca efflux is also inhibited by lanthanum.

Using the value of 0·41 mM calcium/kg axoplasm[8], the average efflux for axons of *Loligo pealeii* (average diameter 450 μm) was 0·25 ± 0·02 pmole cm^{-2} s^{-1} (ref. 10), in good agreement with values in the literature[8,13]. Of this efflux, 87 per cent could be inhibited by lanthanum ions, which seemed to compete with external calcium ions for binding sites on the cell membrane.

Strychnine inhibits the Binding of Glycine to Rat Brain-Cortex Membrane

THE excitatory action of strychnine on the central nervous system results from its ability to antagonize the effect of synaptic inhibition[1]. Recently, evidence has accumulated for glycine as an inhibitory transmitter, especially at lower levels[2,3]. Because strychnine is capable of antagonizing the inhibitory effect of iontophoretically applied glycine[3], the contention is that it does not interfere with transmitter liberation, but interacts with receptors located on postsynaptic membranes, rendering them less sensitive to glycine-mediated inhibition. *In vitro* studies of the mechanism of action of strychnine, concerned chiefly with the active transport of glycine, have invariably yielded negative results[3,4].

We now report experiments concerning the binding of glycine to central nervous system membranes, and the effect of strychnine on it. The membranes used were obtained from dissected cerebral cortices of adult rats of Wistar descent. We followed essentially the procedure of Gray and Whittaker[5], except that the P$_1$ nuclear pellet was also washed once. The P$_2$ large-granule pellet is known to contain nerve-ending particles, with their postsynaptic membranes attached, mitochondria, myelin fragments and some other ill-defined membranes. We suspended it in 20 volumes of twice distilled water at 0° C for 15 min, and then centrifuged at 27,000*g* for 1 h to free it from synaptic vesicles, soluble enzymes and other materials enclosed in the particles and retain only the membrane components. The crude membrane pellet was finally resuspended in 5 ml. of 0·32 M sucrose.

Binding of glycine to the membranes was studied. Membrane suspension (0·1 ml.) was added to test tubes containing inorganic salts and buffer, with a composition similar to that in cerebrospinal fluid (final concentrations being 123 mM NaCl, 2·5 mM KCl, 0·93 mM CaCl$_2$, 0·86 mM MgCl$_2$, 20 mM Tris-HCl (*p*H 7·3), in a final volume of 2·0 ml.). Experimental tubes also contained the amounts of strychnine sulphate indicated in the figures. The reaction was started by adding 1-^{14}C-glycine (10 Ci/mole). Tubes were incubated at 37° C for the times shown in the figures. The reaction was stopped by filtering the tube contents through nitrocellulose membranes ('Millipore' type 'HA', 0·45 μm) and washing rapidly three times with 5 ml. of the indicated salt solution kept at 0° C. The filters with their quantitatively retained membranes and bound glycine were dried at 100° C, and counted in a conventional toluene based scintillator in a Nuclear

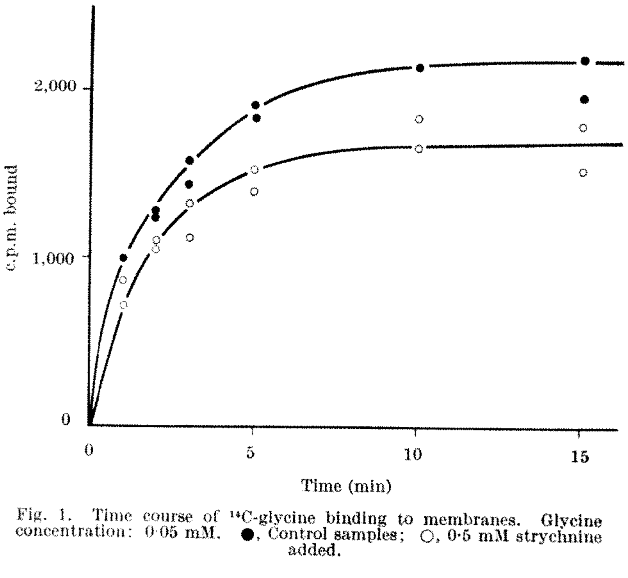

Fig. 1. Time course of ^{14}C-glycine binding to membranes. Glycine concentration: 0·05 mM. ●, Control samples; ○, 0·5 mM strychnine added.

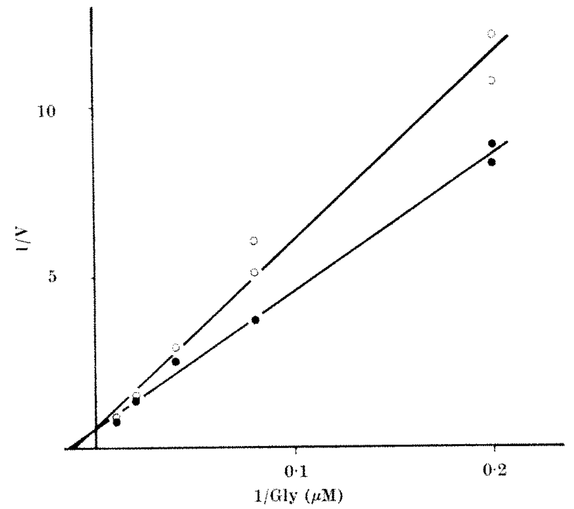

Fig. 2. Lineweaver–Burk plot of ^{14}C-glycine (specific activity 10 Ci/mole) binding to membranes. Reactions were stopped at 1 min of incubation. 1/V is (1/c.p.m.) × 10^3. ●, Control samples; ○, 0·5 mM in strychnine. All determinations were done in duplicate: when only one point appears at a given concentration it is because duplicates coincide.

Chicago scintillation spectrometer. Tubes with a final volume of 10 ml. and kept at 0° C were filtered immediately after adding the membrane suspension. These served as blanks and their radioactivity was subtracted from the experimental tubes.

The binding time-course (Fig. 1) is considerably faster than that observed in studies of glycine transport *in vitro*[4,6]. Initial velocities last only up to 1 min, and at 10 min equilibrium is reached. Strychnine inhibits the binding by about 25 per cent at this concentration. Raising the alkaloid concentration leads to progressively larger inhibitions, till at 10 mM (the greatest tested) it becomes 76 per cent. In some membrane preparations inhibitory effects have been detected at 2·5 μM strychnine, but adequate conditions for obtaining reproducible results at this low concentration have not yet been found. The dependence of initial velocities on glycine concentration (Fig. 2) gives a half-saturation value of 78 μM, which is much lower than that found for glycine transport in brain slices (440 μM) (ref. 6). These kinetic differences between our results and those dealing with transport suggest that both processes are of different nature. The type of inhibition, as seen in a double reciprocal plot, is strictly competitive. This was unexpected, because it may be considered from what we know that glycine binds not only to postsynaptic receptors but also to transport and to non-specific sites, and a more complex type of inhibition by strychnine was predicted. This finding may be interpreted in two ways. Either one of the binding sites greatly predominates over the other two, and strychnine competes with glycine for it, or second, more than one of the theoretical binding sites for glycine contribute appreciably, but all have very similar dissociation constants, on the one hand, for glycine (K_s), and on the other, for strychnine (K_i). The latter alternative seems less probable, but cannot be rejected with the available data.

High strychnine concentrations are generally applied *in vivo* to the cerebral cortex to obtain excitatory effects[8]. This lower sensitivity to the drug, relative to lower neural structures, may be an explanation of the fact that the *in vitro* effect described requires a strychnine concentration much higher than is necessary to suppress inhibition on spinal neurones[3]. It is also frequently the case that elicitation of drug effects *in vitro* need high concentrations[9]. Although the possibility of a less specific *in vitro* effect of strychnine cannot be wholly excluded, its competitive antagonism for glycine binding correlates well with previous physiological data[7], and suggests that this type of study may lead to a better insight into the molecular mechanisms of nervous inhibition and its modification by drugs.

Theories of Milk Secretion: Evidence from the Electron Microscopic Examination of Milk

IN spite of study for over one hundred years, we still do not know how milk is secreted by the mammary cells[1]. One early theory of light microscopists was that the mechanism was holocrine, involving death and release of the whole cell as in sebaceous glands. Indeed, recent biochemical studies have shown that milk contains several intracellular components (such as citrate, enzymes and microsomes), although it is uncertain whether these are derived from secretory or duct cells or from phagocytic cells (neutrophil leucocytes and macrophages), which are known to migrate into milk from the blood and connective tissue. Later, the idea that whole cells are lost was rejected because the observed rate of mitosis was too small to account for the predicted rate of cell renewal. An alternative theory was that the process was apocrine—that only the apex of the cell became detached and that milk consists essentially of cell debris. Subsequent investigators considered this theory was not proven because what seemed in histological sections to be pieces of cytoplasm recently detached from cells could have been portions of neighbouring cells, the greater part of which lay out of the plane of section[2].

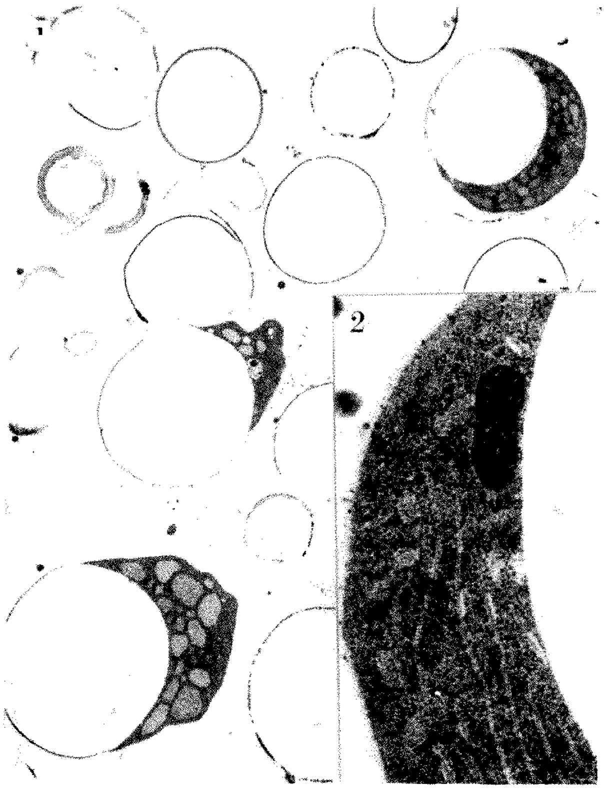
Mammary glands have now been examined with the electron microscope in several laboratories. Bargmann and Knoop[3] proposed that protein particles probably escape when Golgi vacuoles open at the surface and that fat globules are pinched off from the apices of secretory cells with cell membrane around them; holocrine and apocrine mechanisms were rejected. Two groups of workers[4,5], however, have revived the apocrine theory because they found crescents of cytoplasm within the plasmalemma (cell membrane) around some fat globules ("signets") free in the lumen of the alveolus but near the secretory cells. As with light microscopy, it is difficult to be sure that such signets are not connected to neighbouring cells; that they are not would be certain if signets were to be found in large ducts well away from secretory cells. Technically it is difficult to examine the contents of large ducts by electron microscopy. We thought it possible, however, that a few signets might still be present at the teat, that is, in the milk, which can be processed for electron microscopy. We now report the idea to be correct and that, as well as settling the controversy, the examination of milk confirms that an apocrine process is involved in milk secretion as classical histologists described it, because we find that what are generally described in the literature as epithelial cells in milk are pieces of cytoplasm devoid of a nucleus, which we believe also come from the secretory cells in the goat.

Fresh milk (2 ml.) from seven goats and a guinea-pig was mixed with an equal volume of 4 per cent glutaraldehyde and 2 per cent sucrose in 0·1 M phosphate buffer, *p*H 7·2. The mixture was spun at 900*g* for five minutes, producing a floating layer of cream and a pellet of denser protein and cells. The cream and protein pellets were treated separately with Palade's buffered osmium solution, embedded and sectioned by standard techniques. The middle layer contained only protein granules and was not examined in every case.

Fig. 1 shows that the cream contained a significant number of signets identical to those seen in alveoli by Helminen and Ericsson[4] and by Kurosumi *et al.*[5]. Both signets and other lipid globules were bounded by a unit (that is, cell) membrane; this indicates their cellular origin, for the lipid globules deep within the cytoplasm of the secretory cell do not have a bounding membrane, nor does that portion of the lipid globule of the signet adjacent to the cytoplasm. The signets contained rough endoplasmic reticulum, which was often considerably swollen, numerous free ribosomes (Figs. 1 and 2), well preserved mitochondria (Fig. 2) and occasionally membrane bound vesicles containing granules (Fig. 1). These vesicles are identical to those found in the Golgi region of the goat secretory cell (unpublished observations).

It is generally accepted that the unit membrane found around secreted lipid globules represents that part of the plasmalemma of the secretory cell which invests the lipid globule as it is extruded through the cell surface. When the extrusion is almost complete, the globule will be attached to the cell by a narrow neck of cytoplasm. If this neck separates immediately adjacent to the lipid, a globule with no cytoplasm will be produced, as is mostly found in the alveoli and in milk (Fig. 1). If, however, the separation occurs closer to the cytoplasm, then a variable amount of secretory cell cytoplasm will be included and will produce a signet. Signets have been found in all specimens of milk that we have examined, both from normal animals and from those treated with oxytocin (0·1 unit intravenously). A rough estimate suggests that from 1 to 5 per cent of the lipid globules seen were signets.

Examination of pellets from the bottom of the tube showed that, for goat milk, the greater part consisted of closely packed protein granules identical to those seen in Golgi vacuoles in the cell and in the lumina of the alveoli (Fig. 3). As expected, the lowest layer also contained a few neutrophil leucocytes, monocytes and macrophages and an occasional red blood cell, but, unexpectedly, 85 per cent of the total objects seen in any field were cytoplasmic fragments, fewer than 0·1 per cent of which contained nuclei (Fig. 3). Although examination of cows' milk smears by light microscopy for the identification of bacteria and cells is routine in many animal health laboratories, it is surprising that only Paape and Tucker[6] have reported that unidentified cell fragments outnumber leucocytes in normal milk, and that the superior resolution of the electron microscope has not been used to examine normal or diseased milk. In the goat the size of the cytoplasmic fragments varied between 5 and 25 μm; on average they were larger than the neutrophils (Fig. 3). Small lipid droplets were also found in them (Figs. 5 and 6) together with vesicles containing protein granules identical to those in secretory cells. The major difference in the appearance of the fragments and that of alveolar secretory cells was that the endoplasmic reticulum was swollen to a variable degree (Figs. 3–6). Apart from the white blood cells and macrophages, no true cells containing a nucleus have been recognized. Like the signets, the fragments were a constant feature of all goat milk so far examined. The number was similar in the first and last milk removed at a milking but was increased after injecting oxytocin. Again, no nuclei were seen in any of the fragments.



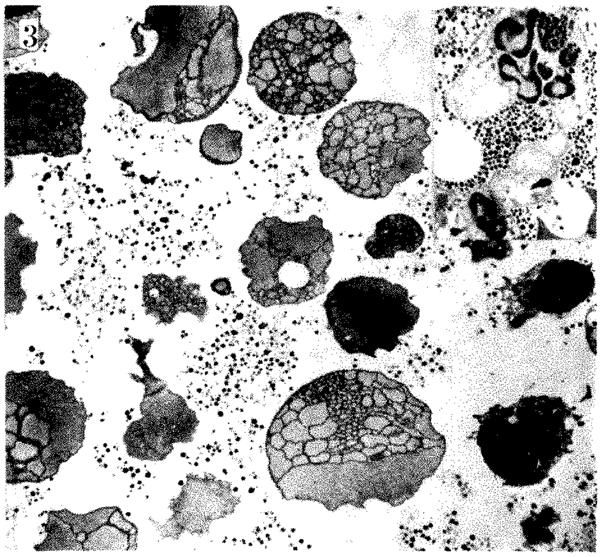


Fig. 1. Micrograph of the floating layer (cream) from goat milk after fixation and centrifugation. It consists largely of lipid globules surrounded by a unit membrane (not resolved at this magnification). Three of the globules shown also have cytoplasmic material on one side and represent the "signets" referred to in the text. (× 4,800.)

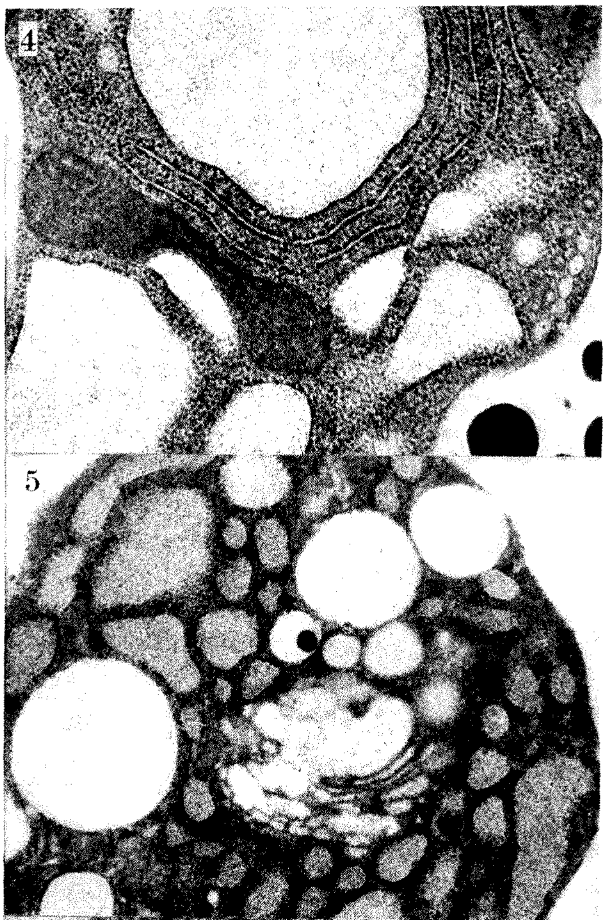
Fig. 2. Higher magnification of the cytoplasmic material present on some lipid globules. A mitochondrion, free ribosomes and cisternae of the rough endoplasmic reticulum can be seen. (× 28,000.)

Fig. 3. Micrograph of the bottom layer of the pellet from goat milk after fixation and centrifugation. The small black dots between the cytoplasmic fragments are the milk protein granules. Two white blood cells (neutrophils) are present on the right hand side of the micrograph. Most of the area of the cytoplasmic fragments is taken up with swollen endoplasmic reticulum. Inset is a macrophage-like cell at the same magnification (× 2,200).

These cell fragments could originate only from phagocytic cells or from the mammary duct and secretory cells. They do not seem to be degenerating or effete mammary cells, which might be expected to contain a nucleus or its remains and cytosegrosomes, which are seen in cells of involuting mammary glands[4], but not a well preserved cell membrane. Nor do they seem to be duct or teat lining cells which would be expected to contain a nucleus, tonofilaments, desmosomes and, if from the teat, keratin. Further, they do not seem to be portions of leucocytes or macrophages because their cytoplasm does not contain neutrophil granules or phagocytotic vesicles. In human colostrum, macrophages have been shown to be ingesting fat and protein granules[7] and, in our preparations of milk, both macrophages and neutrophils contain ingested fat and protein particles which were surrounded by the membrane of the phagocytotic vesicle (Fig. 7), whereas no such membrane was seen around fat droplets in the signets or in the cell fragments (Figs. 1, 2, 4 and 6).



Figs. 4 and 5. Details of two cytoplasmic fragments from different batches of milk. The endoplasmic reticulum is swollen to differing degrees. Fig. 4 contains a central area of stacked vesicles interpreted as part of the Golgi complex immediately beneath which lies a vesicle containing a milk protein granule. A lipid droplet is present to the right of the Golgi area. Fig. 5 shows a mitochondrial profile and both swollen and normal endoplasmic reticulum. Fig. 4, × 22,000; Fig. 5, × 30,000.

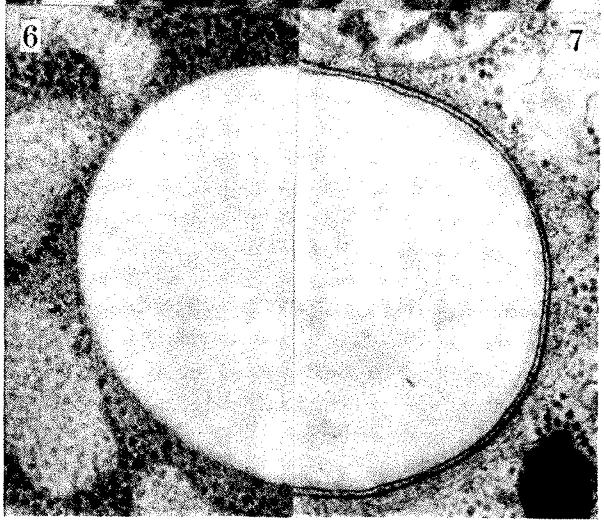


Fig. 6. Part of a lipid droplet in a cytoplasmic fragment. There is no visible membrane bounding the lipid droplet. (× 65,000.)

Fig. 7. Part of a lipid droplet in a leucocyte bounded by a membrane which is in turn surrounded by the membrane of the digestive vacuole. (× 42,500.)

The only other possible source of the fragments is the secretory cells of the alveoli and smallest ducts. Further evidence in favour of this source is that they closely resemble the appearance of the secretory cells, particularly in possessing fat and protein particles, abundant rough endoplasmic reticulum, a hypertrophied Golgi body and intact mitochondria. Admittedly, the endoplasmic reticulum of the milk cell fragments was swollen, but we have also seen such swelling in goat mammary tissue after oxytocin treatment. Our conclusion is therefore that, like the signets, the fragments are part of the secretory cells lost in a classical apocrine manner. The increase in their number seen after an injection of oxytocin may be significant. It seems possible that, in addition to the normal release of large fat globules and the possibly less common pinching off of signets, a cell that is swollen with secretory products well above the level of the tight junction with the next cell might lose part of its apex under the influence of external forces such as myoepithelial cell contraction. An attractive feature of this hypothesis is that the mechanism of milk secretion may vary according to the degree of fullness of individual alveoli.

We thank several colleagues, particularly Professor E. C. Amoroso and Dr T. Gillman, for critical discussions.

Cell Division in the Early Growth and Morphogenesis of the Chick Limb

The confusion concerning the relationship between growth and form in animal development is quite deep and widespread and possibly stems from the title of D'Arcy Thompson's great book[1], together with the botanists' emphasis on localized growth zones such as the apical meristem. Our attention was drawn to this during our studies on budding in hydra[2], where it had always been assumed that formation of a new hydra by budding was partly the result of localized growth at the base of the bud. From our experiments it now seems that bud elongation does not require cell growth and division but is a morphogenetic process involving cell movement and changes in cell contact. This led us to question whether cell growth and division ever determine in a significant manner the form, as distinct from size, of animal tissues and we have had difficulty in finding examples where this is obviously the case. Orientated cell divisions in early development contribute to the morphogenesis of the blastula[3] and are almost certainly important for the determination of form in mosaic embryos. In these cases it is the plane of cell division and not growth that is important. The growth of certain insect structures involves orientated cell divisions and is one of the very few cases where growth seems to determine form[4]. Form seems to be determined by the spatial relationship between the cells which may be largely determined by cell movement and cell contact[3].

The early development of the chick limb[5,6] is characterized by rapid outgrowth and elongation which transform the initial, simple, beehive shape into an elongated structure that is slightly flattened dorso-ventrally. The bud at this stage is made up of undifferentiated loose mesenchyme with an epidermal covering. A prominent ectodermal ridge, most fully developed at the distal end, runs antero-posteriorly. During the early stages of elongation, stages 17 (Hamburger and Hamilton) to about 20, the presumptive regions of the wing along the proximo-distal axis are specified in a proximo-distal sequence[1] (Fig 1), that is, shoulder region, then humerus, then radius and ulna followed by the digits. The presumptive maps up to stage 19 are congruent. This specification of presumptive regions does not imply that regulation is impossible, and considerable regulation is possible[5,6] up to about stage 23 or 24. There are three main questions relating to the growth of the early limb bud: (1) what provides the force for the early outgrowth? (2) what determines the overall paddle shape of the early limb? and (3) what is the relation between the growth of the early limb and the proximo-distal specification of the regions[8]? The last question is raised by the congruence of early presumptive regions and by the claim of Saunders[7], based on carbon making experiments, that only a narrow region at the tip is relevant to increase in length. Amprino[5], too, has claimed that during early stages there is a greater rate of proliferation in the distal mesoderm compared with the proximal. Ede and Law[9] have suggested on the basis of computer simulation that a proximo-distal gradient in growth rate, together with distal movement of the cells, may provide for limb elongation. Of course, distal movement of cells alone could in principle lead to distal elongation. Because adequate quantitative data on mitosis during limb bud outgrowth were unavailable we have investigated it as a first step towards answering the above questions.

White Leghorn embryos were incubated at 38° C and fixed in 5 per cent TCA (Jurand[10]) and double embedded[11]. Sections were cut at 7 μm parallel to the long axis of the limb and at right angles to the dorso-ventral plane. They were stained in haematoxylin and eosin.

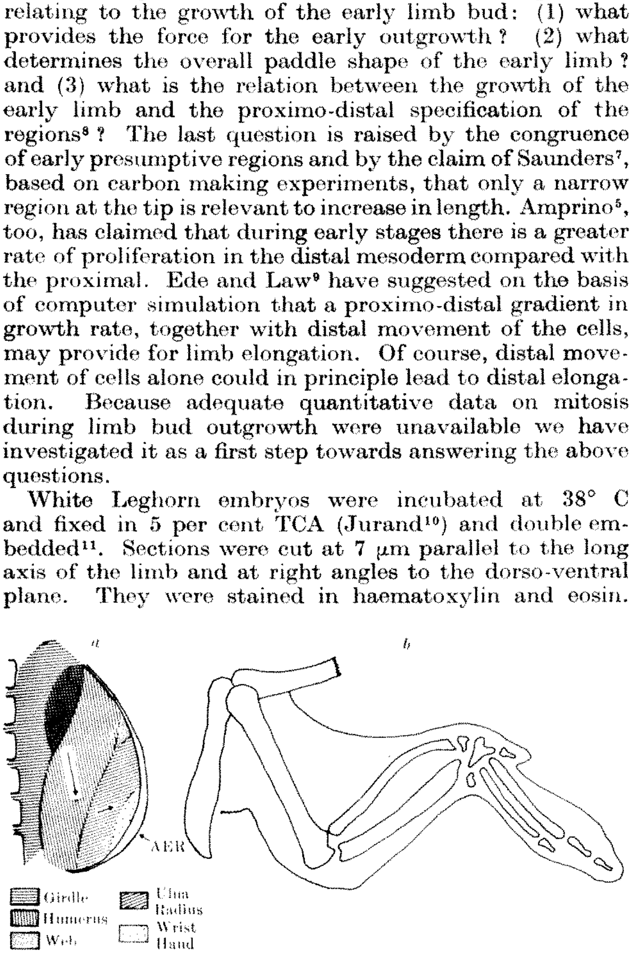

Fig. 1. *a*, Limb bud at stage 19 (after Saunders[7]) to show presumptive regions. AER, Apical ectodermal ridge; *b*, the wing after about 10 days' incubation.

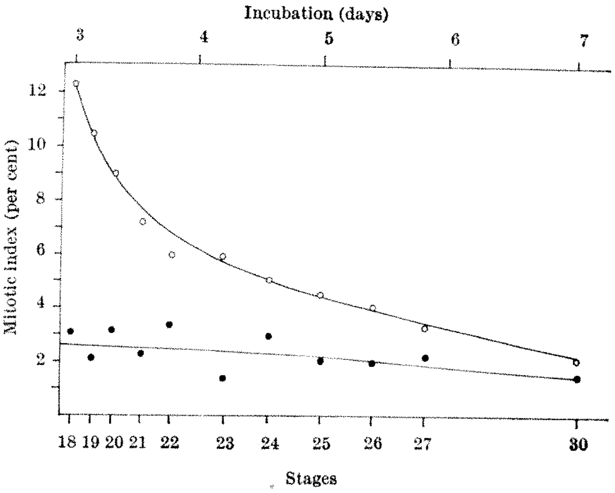

Fig. 2. Overall mitotic index of mesenchyme (○) and ectoderm (●) at different stages.

For the counting of mitoses in the mesenchyme an approximately medial section was chosen together with one section located ten to fifteen sections away on either side. Every cell and every mitosis in these sections were counted under oil immersion, by dividing the section into strips about 150 μm wide and containing not less than 200 cells, and at later stages not less than 500 cells.

The overall mitotic index of the mesenchyme is initially very high, about 10 per cent at stage 18, but drops steadily to about 2 per cent three days later, at stage 30 (Fig. 2). This striking drop in mitotic index could be the result both of an increase in the cell cycle time in relation to that of mitosis and of a reduction in the number of cells dividing. We cannot distinguish the relative contributions of the two factors without a much more elaborate analysis, but we are inclined to suggest that the first is probably more important in early stages, for Searls[12] found that about six hours after injection of tritiated thymidine at stage 22 all nuclei were labelled, but it required ten hours at stage 24. Whatever the cause, a reduction in the mitotic index would be correlated with a reduction in growth rate of the limb if cell division were the main factor providing for its growth. Schmalhausen's[13] data on the increase in mass of the limb show that the growth rate does decrease during early stages. Studies of multiplicative growth of chick wings in terms of DNA content are only available from 5–12 days[14], that is, after stage 26, during which the growth rate is constant. We have, however, observed a small drop in the mitotic index between the fifth and the seventh day of incubation. It is of interest that Nowinski and Yushok estimated the mitotic index in 6–7 day wings (stage 30) at 2·5 per cent, which is in reasonable correspondence with our data.

The overall mitotic index of the ectoderm is also shown in Fig. 2, and fluctuates around 2 per cent. The smaller mitotic index of the ectoderm compared with the mesenchyme may partly be anticipated on the grounds of the volume/surface relationship of the extending bud.

The regional pattern of mitotic indices within the limb bud mesenchyme at various stages is summarized in Fig. 3. Between 18 and 23 there is no significant difference ($P < 0{\cdot}01$) in the mitotic index of proximal and distal regions (as determined by χ^2), but from stages 24 to 30 there is a significant decrease in the mitotic index in the proximal regions compared with the distal regions. The situation during stages 21 to 24 is a little more complicated, for some regions of very high mitotic index were found in localized patches, in the elbow region at stage 21 and in the wrist region at stage 23. The constancy or significance of such localized regions of high mitotic index is not known. Mitoses in the ectoderm seem more or less

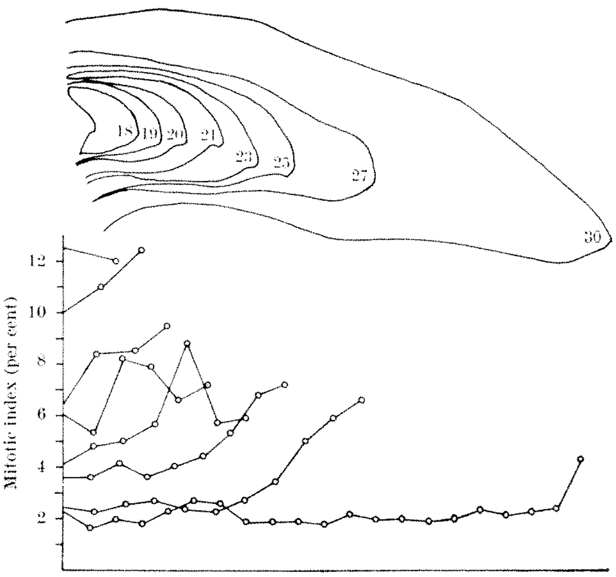

Fig. 3. The axial distribution of mitotic index at different stages. The upper drawings give the outline of the limb at the appropriate stages.

evenly distributed, though occasionally a patch of high mitotic index, apparently associated with synchrony of division, was seen at the tip of the apical ridge.

The orientation of mitoses within the mesenchyme was examined at stages 20 and 24 to look for a preferred plane of cleavage. The scoring of the planes is difficult and, apart from a suggestion that there are fewer divisions in the direction of the long axis, no differences could be claimed.

The results can be summarized by saying that the fall in mitotic index, as the bud grows, occurs more rapidly in the proximal region after stage 24, so that a proximo-distal increase in mitotic index becomes established. Because there is considerable limb bud elongation before stage 24 a gradient in cell division is unlikely to be important in providing a mechanism, although it may have a role in later stages. We would suggest instead that the gradient in cell divisions from stage 24 onwards is related to the regional differences in the limb as can be seen from Fig. 1. The presumptive humerus region is much longer than the presumptive radius and ulna and the presumptive wrist and hand, although by stage 30 the latter are equal in length or even longer than the humerus. This requires that they grow faster. It is of interest that the time of appearance of the gradient is approximately that at which determination of the regions along the proximo-distal axis becomes fixed and at which one would expect them to display different properties. The absence of a gradient in cell division before stage 20 implies that cells are probably changing their presumptive fate in this period and behave according to their positional information[8]. In considering limb bud elongation one should distinguish between the forces producing the outgrowth and those factors determining its form. The forces involved are unknown but may be provided both by the increasing cell volume and the secretion of intercellular matrix. The latter seems particularly likely when, after stage 26 following condensation, the chondroblasts are forced apart by the secretion of matrix. The direction of separation is mainly along the long axis and this could contribute to limb elongation. As regards the overall form of the limb, particularly at earlier stages, we would suggest that it is determined by the ectodermal sheet, whose form is in turn determined by the nature of its intercellular contacts. Our work on sea urchin morphogenesis has suggested that the form of ectodermal sheets may be related to the degree of contact between the cells[3]. More specifically, a large degree of contact was always associated with an increased curvature of the sheet. A similar situation seems to occur in the limb bud, the apical ridge being the region of increased cellular contact and increased curvature. Electron microscopy of limb buds confirms the idea that the form is determined by the ectoderm, for it appears as a discrete structural layer in contrast to the rather spongy mesenchyme.

Finally, it is necessary to consider the factors involved in the reduction of the initially very high mitotic index. It will be important to know whether this is part of a temporal programme of the limb bud cells or is determined by the cells' positional information and the measurement of limb bud length.

This work is supported by the Nuffield Foundation. We thank Mr P. Gould and Dr D. Gingell for their comments.

Viral Components in the Genetic Background?

EXTRACHROMOSOMAL hereditary elements may be very much more important than present genetic convention supposes, and Gruneberg's[1] hypothesis that extranuclear entities are responsible for differentiation in skeletal patterns between sublines of mice is intriguing. But the rejection of the alternative view that changes in nuclear genes are responsible for this effect is supported by an argument that is not wholly convincing.

The crucial difficulty in explaining this differentiation by mutation of nuclear genes is that a mutation rate per gamete of 10^{-2} is inferred from data on skeletal variants and is incompatible with rates of mutation of the order of 10^{-6} observed by Russell and others. We should note, however, that Russell's data are for specific loci while Gruneberg's data are for skeletal characters. Some, perhaps all, of these may be regarded as quantitative or quasi-quantitative, and we may therefore ask how many loci may be involved in determining such characters and what estimates of mutation rates are available for such loci.

As far as I am aware, no systematic attempt has been made to determine directly, by genetic analysis, the number of loci (polygenes) governing a quantitative character, although Thoday[2] has shown that they can be characterized and mapped with suitable methods. Davies[3] has mapped loci influencing sternopleural chaeta number in a series of lines of *Drosophila melanogaster* in which selection on this character had taken place. His findings indicate that at least sixteen loci must be concerned with this character, and if other work is taken into consideration the number rises to twenty or possibly more. There is no reason why sternopleural bristle number should be atypical of quantitative characters in general and it seems likely that the skeletal characters used by Gruneberg will have similar genetic bases. If this is so, clearly the "per locus" mutation rate might be one twentieth of the figure given in the paper, or about 5 × 10^4. Further, because the estimate of twenty loci may be appreciably smaller than the average number of operative loci per character, the true value of the mutation rate may be smaller still.

The mode of action of such genes acting on one character may be very different from locus to locus, as Spickett[4] has shown. He analysed the effect of "high" alleles at two loci affecting sternopleural chaeta number in *Drosophila* and showed that one worked by increasing fly size and therefore bristle number generally, while the other increased the number of bristles in the ventral portion of the sternopleural region.

In a few cases it has proved possible to connect genes affecting quantitative characters more directly with their immediate products. Ashton *et al.*[5] have shown that about 10 per cent of the genetic variation of milk yield in given herds can be ascribed to the polymorphism for two transferrin alleles giving electrophoretically distinguishable products. A milk polygene is a transferrin major gene. In my laboratory Birley has been able to show that a similar situation exists with respect to rate of development and polymorphism at the esterase-6 locus in *Drosophila melanogaster*. In his material about 19 per cent of the phenotypic variance of speed of development is attributable to this polymorphism, and the esterase major gene is a developmental rate polygene. Data of this sort make it easier to accommodate polygenes within the framework of knowledge of gene action.

Next we have to consider estimates of mutation rates. Classically these have depended largely on methods like that of scoring sex-linked lethal mutations in *Drosophila* and coat colour mutations in mice and they lead to estimates of mutation rate of about 10^{-6}/locus. Other workers, however, have produced evidence which suggests that this figure may be too small. Whitfield *et al.*[6] concluded that many mutations giving an altered protein in *Salmonella* were probably not picked up by the selective techniques used so often in mutation work. Mukai[7] found that the rate of mutation of viability genes was twenty times greater than that for mutations to lethality in the same chromosomes. Confirmation of these data is desirable but, at face value, they suggest that estimates of mutation rate could therefore be appreciably smaller than the real values. The discrepancy between the two types of estimate is resolved by recognizing that the first group is scoring only mutations of large effect while in the second group, with a greater resolving power, more mutations of smaller effect are picked up and greater values for mutation rate are therefore obtained. On the very reasonable assumption that, on average, a locus can mutate in many more ways to produce slightly altered function than to produce drastically altered function, it may be concluded that the "real" rate of mutation in which all types of mutational change are considered as summed together may be one order of magnitude greater than that indicated by coat colour and lethal studies or, say, 10^{-5}.

Now the genetic situation used by Mukai was that of isogenic chromosomes in which spontaneous viability mutations were accumulated and scored. It is thus to some extent comparable with the inbred and highly homozygous material used by Gruneberg, in which quantitative morphological characters were scored. It is not unreasonable, therefore, to suppose that the resolving power of Gruneberg's system may be more similar to that of Mukai than it is to the systems using lethals and coat colour genes. If this is the case the maximum observed mutation rate "per locus" of 5×10^{-4} should be compared with an expected value of 10^{-5}. In fact, Gruneberg states that the number of mutations in the mouse lines may be overestimated; taking his lower limit the observed mutation rate becomes $2{\cdot}16 \times 10^{-4}$. The agreement between observed and expected mutation rates, calculated in the way I suggest, cannot yet reasonably exclude the idea that differentiation in inbred mice sublines takes place by fixation of nuclear gene mutations.

Migrating Marsupials and Drifting Continents

Martin[1] has discussed the problem of the present distribution of marsupials, confined to the Australian region and to South America (with a little comparatively recent immigration into North America). He concluded that marsupials could not have entered Australia from either Asia or Antarctica and suggested instead that they had evolved in a land mass originally situated in the central Pacific over the position of the Darwin Rise, the activity of which had split the land mass in the early Jurassic. One portion then drifted south-west, forming part of New Guinea and the now sunken Coral Sea Platform, so delivering its cargo of marsupials to Australia. The other half had drifted north-east to become incorporated in North America, its marsupials then colonizing that continent and eventually spreading to South America.

Martin's theory seems to be at such fundamental variance with the bulk of the present picture of continental movements and directions of sea-floor spreading that it could only be justifiable if it were the sole reasonable explanation of the known facts of palaeozoogeography. How the ancestors of the marsupials arrived in Martin's isolated mid-Pacific land mass is not the least of the problems involved in his theory, and I believe that other, more simple, theories explain the known facts at least as adequately.

As is well known, the problem peculiar to Australia is the presence there of marsupials but not of placentals. It has been commonly accepted that both groups appeared at approximately the same time. Acceptance of this view in turn implied that any easy route of access to Australia would have been traversed by both groups. Because this had not taken place, the implication was that there had never, since the evolution of the two groups, been a continuous land bridge between Australia and the rest of the world. Instead, the geographical character of the area had always been broadly as it is today, and the spread of both placentals and marsupials had been hindered by the existence of a number of sea barriers of varying width. The chances of either group making the complete passage from Asia to Australia were small; by chance, the marsupials had succeeded and the placentals had not.

The many discussions of the best positions through which to draw a line to demarcate the Australian zoogeographic region from the Oriental zoogeographic region (Wallace's Line, Weber's Line, Lydekker's Line, and so on) have stimulated much study of the faunas of the islands lying between Malaya and Australia. Nevertheless, it does not seem to have been realized that these faunas provide strong evidence against the view that marsupials spread along this chain of islands, followed at a later date by the placentals. If this had taken place, one would have expected the marsupials to have colonized the majority of these islands, and to have undergone some adaptive radiation there before the placentals arrived. Even if a variety of placentals had later colonized the islands, and even though they in general succeed when in competition with marsupials, it would have been surprising if they had completely exterminated every species of marsupial from nearly every island. Because few placentals have in fact succeeded in spreading to the islands east and north of the limits of the Sunda (Asian) continental shelf, it would be all the more expected that a variety of marsupials would still be found in many of the islands, particularly the northern fringe of islands, such as the Philippines. This, however, is not the case. In fact, the faunal picture is not of an existing marsupial fauna in the islands being progressively replaced from the west by invading placentals. Instead, it is of an archipelago, originally lacking any type of mammal, which is still being colonized—by placentals from the west and by marsupials from the east. Thus Darlington[2] refers to this area as a zone of subtraction and transition, and stated that Wallace's Line "separates the nearly full-scale Oriental fauna from a strikingly depauperate fauna". Darlington believes that the area has been colonized by vertebrates rather recently, and that more Oriental (that is, placental) groups than Australian (that is, marsupial) groups have extended into the area—a surprising fact if the marsupials had migrated through the region before the placentals. Similarly, Simpson[3] states: "From Australia marsupials have spread with a completely regular pattern of progressive attenuation as far as the Solomons to the north-east, Talaut to the north, and Celebes to the west." (Fig. 1.)

The clear implication of all the preceding facts is that marsupials did not reach Australia from Asia, and in this I agree with Martin.

In any discussion of faunal migrations in the late Mesozoic and early Tertiary, one of the greatest gaps in our knowledge is our almost complete ignorance of the reptile and mammal faunas of Africa through this time. A few large dinosaurs were found in the earlier part of this century, in the Upper Cretaceous of South Africa. These deposits have not yet, however, been re-examined with the care necessary to reveal the remains of the tiny early mammals, and it cannot therefore be assumed that they were absent from Africa. The earliest known mammals, *Erythrotherium* and *Megazostrodon*, were found in the Upper Triassic of southern Africa[4,5] and a single Upper Jurassic mammal, probably a pantothere, has been found in Tanzania[6]. The presence of Cretaceous dinosaurs in Africa suggests that there was still, from time to time at least, land connexions between that continent and Laurasia, where there was a varied dinosaur fauna (though it is also possible that these Cretaceous dinosaurs were merely the descendants of dinosaurs known to have existed in Africa in the Jurassic). At the very least, there is no evidence to rule out the possibility that marsupials were able to enter Africa some time during the Cretaceous. As in other continents, they would later have become extinct there because of competition from placentals in the early Tertiary.

If early mammals lived in Africa, the problem of their access to Australia depends on the precise times of origin of the marsupials and of the placentals, and of the time at which a land connexion to Australia was severed.

As has already been noted, a direct continuous land access-route to Australia will not explain the absence of placentals from that continent if these originated before, or at the same time as, the marsupials. But there is no evidence to make such an assumption necessary. The precise time of origin is unknown for either group. All

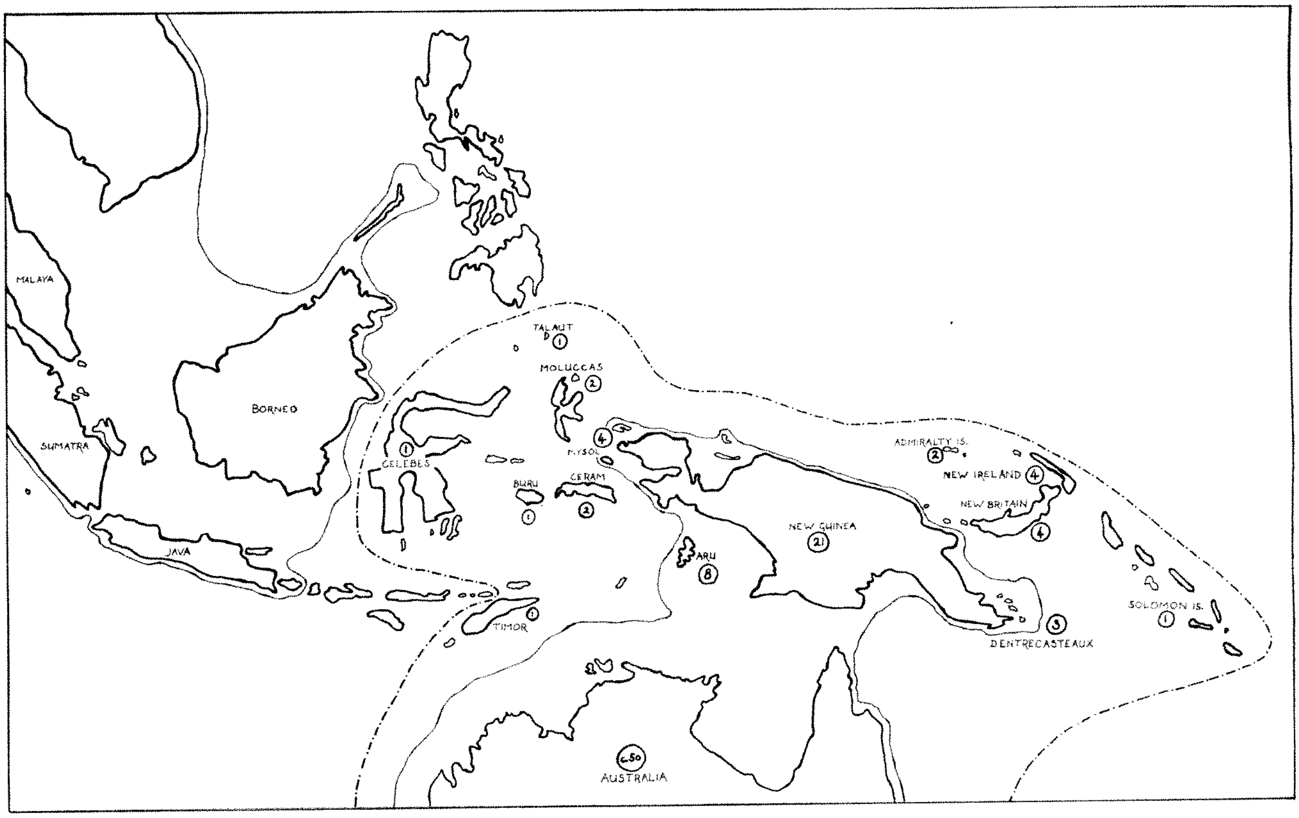

Fig. 1. **Islands of the Australasian region.** Figures indicate number of marsupial genera, after Simpson[3]. ———, Continental shelf (200 m contour); — · — · —, limit of marsupial distribution.

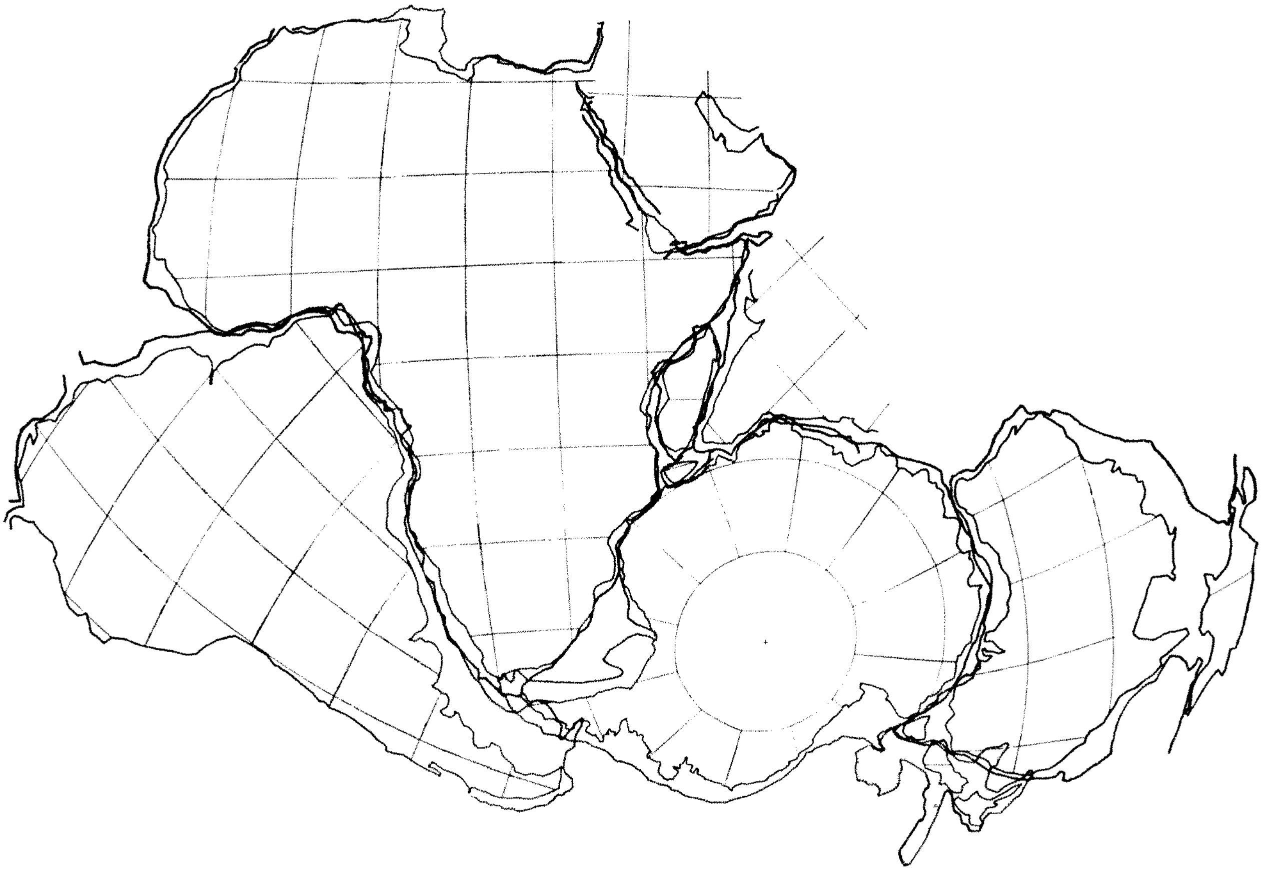

Fig. 2. The fit of the southern continents, from Smith and Hallam[10].

that is known is that members of both groups, identified by their different tooth patterns, were in existence in the Albian (Middle Cretaceous) of North America[7,8]. There is no reason here to assume that both groups had an equally long earlier history. Another possible reason for such an assumption would be the belief that the two groups were divergently specialized descendants of a common oviparous ancestral stock. In fact, as Lillegraven[9] has shown, it is far more reasonable to believe that the common ancestral stock was already essentially marsupial, and that the placentals are therefore specialized marsupials. He states: "It is my opinion that if it were possible to study living specimens of the ancestral therian stock, most observers would not hesitate to assign them to the infraclass Metatheria, order Marsupialia".

The few relevant facts, then, suggest that marsupials were in existence before the placentals. If so, the existence of Mid-Cretaceous placentals in turn suggests that the marsupials had differentiated by the Lower Cretaceous at the latest, having evolved from the Jurassic pantotheres[5]. If it is also accepted that they may have been able to spread to Africa at that time, the problem of deciding whether they could have spread from there to Australia is reduced to that of determining the time by which land access to that continent had been broken. In their discussion of the fit and break-up of the southern continents, Smith and Hallam[10] place Antarctica between the eastern side of Africa and the southern side of Australia (Fig. 2), providing a simple land route between these two continents. Discussing the time of break-up of Gondwanaland and of dispersal of the resulting continents, they state: "Palaeozoogeographic data on the distribution of terrestrial vertebrates and neritic molluscs suggest that widespread land connexions and negligible seaways existed between most of the fragments of Gondwanaland until well into the Cretaceous period." They conclude that, although much of the initial rifting (that is, small displacements of up to 100 km) probably occurred in Jurassic and Lower Cretaceous times, much of the dispersal occurred in Upper Cretaceous and Tertiary times. Smith and Hallam note the significance here of the syntheses of palaeomagnetic data by Briden[11] and McElhinny[12], both of which indicate that the divergence of their polar wandering curves shows significant dispersal of the Gondwanaland continents to have begun in the Middle Cretaceous. All this evidence, therefore, permits the suggestion that marsupials could have migrated from Africa to Australia via Antarctica in the Lower Cretaceous. The present climate of Antarctica is in itself, of course, a sufficient explanation of the present lack of marsupials in that continent and of our lack of any record of their presence there in the Cretaceous.

To summarize, then, it is likely that marsupial mammals were in existence before the placentals, which may have evolved from them later. It is at least possible that the marsupials were able to migrate throughout Africa, Antarctica and Australia before the Antarctica–Australia land mass separated from Africa, and that this in turn took place before the placentals reached Antarctica–Australia.

My theory, like Martin's, suggests the presence of marsupials in lands where they are unknown at present and unrecorded in the past. Because this is true of both of Australia's nearest neighbouring continents, such suggestions are an inevitable part of any theory of the origin of Australian marsupials, unless there were originally a direct connexion between Australia and South America. My theory, unlike Martin's, places these unknown marsupials on lands which are known to have existed, and whose movements do not conflict with the generally accepted theories of the directions of movement of the continents, and of sea-floor spreading, during the late Mesozoic and Tertiary.

Resistance to *Claviceps purpurea* in Spring and Durum Wheat

The ergot fungus, *Claviceps purpurea* (Fr.) Tul., is common on cereals and grasses throughout the temperate regions of North America[1,2]. It is often severe on rye (*Secale cereale* L.) and durum wheat (*Triticum durum* Desf.) and in recent years it has also been troublesome on Triticale (*Triticum* sp. × *S. cereale*) and on male sterile cultivars and lines used in the development of hybrid spring wheat (*Triticum aestivum* L.) at the University of Manitoba. Field observations in the past have indicated that some cultivars of either spring or durum wheat are more susceptible than others[3], but experimental evidence of resistance has not been reported. We therefore investigated the variability of the infection reaction to *C. purpurea* in the cultivated cereals, aiming to find possible sources of resistance for use in the Triticale and hybrid wheat breeding programmes.

During these investigations two cultivars, one of spring wheat and one of durum wheat, were found to possess a higher resistance to ergot. These two cultivars were tested more extensively, along with two susceptible ones, and the results of the tests are the subject of this communication. A more detailed account of our studies, dealing with the selection and virulence of isolates and the testing procedures as well as the variability of the infection reaction in cultivated cereals, will be published elsewhere.

Ergot sclerotia were collected from the spring wheat cultivar "Manitou" and from the Triticale cultivar "Rosner". Two isolates from each cultivar were obtained by culturing surface-sterilized sclerotial pieces on acid malt agar. Conidia were increased as required in liquid shake culture[4]. The mycelium was removed by filtration and the spore density was adjusted to approximately 10^4 conidia/ml. with sterile distilled water. Plants of the wheat cultivars listed in Table 1 were grown in the greenhouse and inoculated two days before anthesis. Ten florets per head were inoculated by hypodermic syringe, injecting 0·02 ml. of the spore suspension into each floret. At least five heads of each cultivar were inoculated with each of the four ergot isolates and immediately covered with a small glassine envelope. The experiments were repeated four times for all cultivars, except "Carleton", which was tested twice. The inoculated florets were rated for the amount of honeydew produced ten days after inoculations. After twenty-one days, the number of sclerotia formed was recorded and the sclerotia were rated for size.

The response of the four cultivars to each of the four ergot isolates was identical to that obtained in our preliminary experiments and only the results of inoculations with an isolate from the "Manitou" cultivar are presented in Table 1. "Kenya Farmer" and "Carleton" were clearly more resistant than "Manitou" and "Stewart 63". Resistance is expressed by a decrease in the number of sclerotia formed, and a reduction in the amount of honeydew produced and in the size of the sclerotia. In the case of "Manitou" and "Stewart 63", the number of sclerotia produced per head is a fairly accurate index of the amount of infection. In the absence of sclerotia, normal kernels were found in the majority of the inoculated florets. In the case of "Kenya Farmer" and "Carleton", however, no kernels were found in florets where sclerotia were absent. Such florets contained small, discoloured and shrivelled ovaries or undeveloped kernels. It seems that the florets were infected and that further development of the fungus was inhibited. The nature of this reaction is still being investigated.

Table 1. RESPONSE OF WHEAT CULTIVARS INOCULATED WITH AN ISOLATE OF *Claviceps purpurea* FROM MANITOU WHEAT*

Cultivar	Percentage of florets with sclerotia§	Size of sclerotia‖	Amount of honeydew produced¶
Manitou†	70	2	3
Kenya Farmer†	26	1	1
Stewart 63‡	78	3	4
Carleton‡	42	1	2

* Inoculum concentration 10^4 conidia/ml.
† *Triticum aestivum* L. c.v.
‡ *Triticum durum* Desf. c.v.
§ Based on a total of five heads with ten inoculated florets/head.
‖ Visual rating of sclerotia size measured twenty-one days after inoculation.
(1) Sclerotia very small.
(2) Sclerotia approximately the size of normal kernel.
(3) Sclerotia larger than kernel, extending beyond the glumes.
¶ Visual rating of honeydew production measured ten days after inoculation.
(1) No visible honeydew.
(2) Honeydew confined within glumes.
(3) Honeydew exuding from infected florets in small drops.
(4) Honeydew exuding from infected florets in large drops and running down the head.

In the summer of 1969, "Kenya Farmer" was tested further at a disease nursery in conditions of natural infection and adjacent to a susceptible cultivar. In these conditions, a considerable number of sclerotia were observed in the susceptible cultivars. In "Kenya Farmer", however, only a few small sclerotia, of the size obtained in the greenhouse experiments, were recovered from a 20 foot row. Subsequently, an isolate was obtained from one of the "Kenya Farmer" sclerotia and used to inoculate this cultivar in the greenhouse. This isolate induced the same reactions as the previous isolates tested.

The resistance of "Kenya Farmer" and "Carleton" is expected to be adequate. Although infection can occur, honeydew production is very small and secondary infection should therefore be minimal. Furthermore, the fact that only low numbers of very small sclerotia are produced should reduce the amount of primary inoculum the next spring.

The resistance of "Kenya Farmer" was not influenced by the range of conditions in the greenhouse, and was maintained when plants were inoculated with some common biotypes of the fungus in our area. "Carleton" was not tested as extensively, but its resistance seems to be similar to that of "Kenya Farmer". Both cultivars are now being tested against a wider range of isolates, and studies on the inheritance of their resistance are in progress.

Benlate-induced Instability of *Aspergillus* Diploids

BENOMYL is the proprietary name of the fungicide in which the active ingredient is benlate (methyl 1-(butyl carbamoyl)-2-benzimidazole carbamate). After extensive trials over the past few years it has been widely reported to be effective in controlling many phytopathogenic fungi and was released for commercial use in 1969. I wish to draw attention to experiments with *Aspergillus nidulans* which show that benlate radically alters the stability of diploid strains.

Heterozygous diploid strains of *A. nidulans* are easily selected[1] and occasionally form new diploid and haploid genotypes during vegetative growth[2]. These spontaneous segregants are formed after mitotic recombination and mitotic non-disjunction, and their occurrence is visually detectable in diploids heterozygous for genes controlling conidial colour. Segregants appear as distinctly coloured sectors in colonies grown from single uninucleate conidia. The diploid strain used in the experiments with benlate had green conidia, and because it was heterozygous for two genes

$$\left(\frac{W\ \ Y}{+\ \ y}\right)$$

affecting conidial colour both white and yellow segregants could be recognized. Conidia of this diploid genotype were spread on complete medium, and on complete medium containing benlate at the concentrations given in Table 1. Survival was estimated as the number of conidia which formed colonies, and colonies were scored as segregating if they contained either white or yellow sectors.

Table 1. EFFECT OF BENLATE ON SURVIVAL AND SEGREGATION OF A DIPLOID *Aspergillus* (bi-1 w(Y)/ad-9 methA-17 y)

Treatment	Survival		Colonies showing segregation	
	Number	Per cent	Number	Per cent
Control (no benlate)	87	100	4·7	5·4
0·25 p.p.m. benlate	75·3	86·6	31	41·2
0·5 p.p.m. benlate	42·7	49·1	30·6	71·6

Numbers are means of four replicates. Concentrations are given in parts per million. The gene symbols are those in regular use.

Besides inhibiting colony formation, benlate also markedly reduced the size of the colonies formed at the highest concentration. The sectors (segregants) were not only more numerous on the benlate containing media but also occupied a much larger area of the colony, indicating that in the presence of benlate the segregational events occurred earlier in the growth of the colony. Indeed, most of the spontaneous sectors consisted of only a few conidiophores. Further investigation showed that few of the spontaneous segregants were haploid (5/36), and that a larger proportion of segregants formed on 0·5 p.p.m. benlate were haploid (33/72). The corresponding proportions of haploid segregants from another diploid were respectively 3/26 and 48/51. Apparently benlate not only induced the formation of segregants but also significantly increased the proportion of haploid segregants. Benlate-induced sectoring was not detected in haploid strains, and no benlate-induced reversions of auxotrophic mutants were detected in the same strains. These results suggest that benlate may not cause gene mutations.

The effect of benlate is at least superficially similar to the induction of haploidization in *Aspergillus* diploids by *p*-fluorophenylalanine[3]. This is an antimetabolite of phenylalanine and its incorporation into cell proteins[4,5] is perhaps responsible for its production of aberrant spindles in dividing human cells[6]. Thus *p*-fluorophenylalanine is probably directly involved with chromosome segregation. Benlate may also operate directly on chromosome segregation, but its very different molecular structure indicates a different primary metabolic action. Mutagens that break chromosomes also cause instability of *Aspergillus* diploids[7,8]. Kafer[8] postulates that these have an indirect effect on stability. Chromosome breakage leads to the formation of nuclei hemizygous for the respective chromosome regions at subsequent nuclear divisions, and these nuclei are potentially unstable. Whatever the primary action of benlate, it evidently has genetic consequences in *Aspergillus*. Searches for possible cytological and genetical effects in other species are required in view of the likelihood that benlate will be widely used in agriculture. I have seen no reports of relevant experiments.

Inhibition of Nematode Infestation of Wheat Seedlings by *Polygonum hydropiper*

SOME nematode diseases of crop plants are ameliorated by *Brassica*, *Tagetes* or *Asparagus* grown previously or concurrently in the same soil[1-5]. Toxic principles within their roots or exuded into the soil are thought to be responsible. Having observed that leaf and root extracts of *Polygonum hydropiper* L. have nematostatic properties against *Rhabditis* and other soil nematodes *in vitro*[6], I decided to study its effect on wheat disease caused by the wheat gall nematode, *Anguina tritici*.

Wheat seeds (variety "Red Coat") were surface sterilized, germinated at room temperature (28° C) and each sown in a pot (diameter 25 cm) of sterilized sandy soil supplemented with fertilizer. Sixteen seedlings of *P. hydropiper* at the eight or nine leaf stage (12–15 cm tall) were washed in distilled water and planted in eight of the pots. After 2 weeks wheat seedlings at the four leaf stage (6 cm tall) were transferred to all sixteen pots, those with *Polygonum* receiving two each and the rest four each. Half the pots containing *Polygonum* and wheat, and half those containing wheat alone, were inoculated with *A. tritici* (six galls/pot) and the remaining pots served as uninoculated controls. The pots were then soaked in water to soften the galls and release the nematode larvae which, although 10 yr old, contained active larvae. Within 4 weeks of inoculation heart leaves of some wheat seedlings were finely wrinkled and rolled and some stems were bent—symptoms of disease caused by *Anguina*[7]. After 7 weeks the intensity of disease was assessed. In pots without *Polygonum*, two wheat seedlings out of the four present were examined at random. Using the Baermann[8] technique many *Anguina* larvae were extracted from infested plants.

Table 1. EFFECT OF *P. hydropiper* ON THE INCIDENCE OF FOLIAGE SYMPTOMS OF WHEAT CAUSED BY *A. tritici*

Test	No. of wheat plants	Total leaves of wheat plant	Healthy leaves/plant	Diseased
Wheat only				
uninoculated	6*	97·8	All	None
inoculated	8	85·0 ± 12·0†	54·5 ± 7·9	36 per cent
Wheat plus *Polygonum*				
uninoculated	8	54·0	All	None
inoculated	8	52·6 ± 6·3	54·4 ± 7·8	4 per cent

* One pot lost. † Standard error.

Table 1 shows that most wheat leaves remained healthy when grown together with *P. hydropiper*. Nothing is known of the way in which *P. hydropiper* influences *A. tritici*, but possibly its root diffusates are toxic and prevent emerging larvae from moving and invading the host plants. Fewer leaves were produced by the wheat plants when they were grown together with *Polygonum*, probably because of competition for light, water and nutrients, but toxic root diffusates may also have been involved.

I thank Dr A. Morgan Golden, US Department of Agriculture, Beltsville, for wheat galls and grains and Dr R. P. Purkayastha, Department of Botany, Visva-Bharati University, for his help.

Effect of Cobalt Applications to Pasture on Herbage Digestibility

THE importance and essential role of vitamin B_{12} and cobalt, its precursor, in ruminant nutrition and metabolism have been described[1-3]. Cobalt deficiency in sheep results in marked changes in the rumen microflora[4], and although some difference in the efficiency of fibre digestion may thus be expected to follow, there is little evidence to support this. Marston *et al.*[2] state that the rate and course of carbohydrate fermentation are unaffected by low cobalt levels in the rumen. Other workers have reported that cobalt supplements increased the digestibility of fibre[5,6], while Becker and Smith[7] found fibre digestibility to be reduced by cobalt supplementation, although the digestibility of ether extract and nitrogen-free extract increased.

This communication presents evidence of a substantial increase in digestibility after the application of small quantities of cobalt to pasture. Chemical analysis of Italian ryegrass (var. RVP) and perennial ryegrass (var. Reveille) showed both grasses to have a low cobalt content. Cobalt sulphate solution was therefore sprayed in early March on to half of each pasture (200 g Co per ha) (+Co) the other half being left untreated (−Co). Eight weeks after spraying, the grasses were harvested separately and artificially dried. The application of cobalt had no effect on herbage growth or on its botanical composition. Chemical analysis showed nitrogen (2·0–2·2 per cent) and fibre (26·5–28·6 per cent) contents to be similar for both varieties and to be unaffected by the cobalt application. Both varieties seemed to contain nutritionally adequate quantities of minerals other than cobalt, although Reveille showed a low content of calcium (0·27 per cent). Cobalt application significantly increased herbage cobalt content (Table 1) and, on the basis of published estimates[8], the untreated RVP was deficient, and the untreated Reveille marginally adequate, for lambs.

The artificially dried grasses were offered to four groups of six (three month old) lambs for nine weeks before digestibility was determined. No significant difference in the amount of feed consumed per day occurred between the groups offered the +Co and −Co herbages of either variety. For the first six weeks, lambs offered the +Co and −Co Reveille herbages gained weight at the same rate, but in the last three weeks the +Co group gained significantly more weight ($P = 0{\cdot}01$). There was no difference in the live weight gain of lambs offered the +Co and −Co RVP herbages.

After nine weeks the digestibility of each herbage was estimated, using three lambs from each of the four groups in the previous experiment. Faeces and urine were collected for eight days after a preliminary feeding period of ten days, and the lambs had therefore been offered the experimental feeds for over ten weeks before digestibility was determined. The digestibility of dry matter, organic matter and fibre was significantly higher ($P = 0{\cdot}01$) for the +Co than for the −Co Reveille herbages, but there was no difference in digestibility between the +Co and −Co RVP herbages (Table 1). There were no significant differences between treatments in intake of feed.

Table 1. COBALT CONTENT, DRY MATTER INTAKE AND DIGESTIBILITY OF THE EXPERIMENTAL FEEDS

			Mean values for three lambs		
Feeds	Co content (p.p.m.)	Intake (g $KgW^{0.73}$ per day)	Percentage of dry matter digested	Percentage of organic matter digested	Percentage of fibre digested
RVP +Co	0·25 †	69 *NS*	67 *NS*	70 *NS*	60 *NS*
−Co	0·06	59	67	69	62
S.E. of difference	0·01	4·3	0·50	0·68	1·96
Reveille +Co	0·27 †	58 *NS*	72 *	74 *	72 *
−Co	0·11	61	66	69	65
S.E. of difference	0·01	3·7	0·91	0·79	0·88

NS, Not significant.
* Significant difference at $P = 0{\cdot}01$.
† Significant difference at $P = 0{\cdot}001$.

It is clear that, in certain circumstances, the digestibility of a grass variety may be substantially influenced by changes in cobalt content. It seems that in the present experiments the increase in liveweight gain noted in lambs offered the +Co Reveille herbage may be attributed largely to its greater digestibility. The fact that the additional cobalt did not influence liveweight gain over the first six weeks of feeding suggests that the difference in digestibility arose after the sixth week and that the effect may be caused by change in the rumen flora. A surprising feature of the results is that further cobalt did not affect the digestibility of the RVP ryegrass, although it contained less cobalt than the Reveille. This may indicate a difference in the availability of cobalt in the two varieties, and requires further investigation.

These experiments are being continued, but there are several implications already. In certain circumstances, the provision of extra cobalt seems to stimulate rumen activity and to increase fibre digestion. In herbage evaluation using *in vitro* digestion techniques, changes in the digestibility of varieties as a result of mineral deficiencies may not necessarily be found, for the inoculum used may be rich in cobalt. Finally, improved animal production may be possible by the application of trace amounts of cobalt to certain herbage varieties.

I thank Professor P. T. Thomas for his interest in this work and Mr Roy Hughes and his colleagues in the Agronomy Department for their collaboration.

GROWTH CYCLES

Is the Business Cycle Obsolete?

Edited by M. Bronfenbrenner. Pp. xii+567. (Wiley (Interscience): London and New York, March 1970.) 120*s*.

Economists and economic historians have long been fascinated by the way in which economic activity tends to fluctuate over time, and many theories have been put forward to explain cyclical behaviour. The papers in this volume (an outcrop of a conference held in London in April 1967) are primarily concerned, however, with the question of whether the business cycle is now defunct. The selection includes a number of case studies of individual countries, both capitalist and socialist, three econometric studies and two general articles on business cycle policies and the transmission of fluctuations from developed to underdeveloped countries. It is an impressive collection of papers written by distinguished scholars.

The general consensus of opinion seems to be that business cycles are still with us but that their characteristics are somewhat different from those before the war. Broadly speaking, cycles are shorter and less intense than they were previously, and in many cases high floors in the downswing have resulted in what might be termed "growth cycles" in which the recessions are characterized by decelerations in rates of growth rather than by absolute contractions in economic activity. Even these modified cycles may be on the way to extinction given the progress in macroeconomic and econometric model building and forecasting.

It is impossible to summarize briefly the great deal of information contained in this volume and, in any case, there is a long and very competent survey of the whole proceedings by the editor at the end of the volume. Unfortunately, the discussion of the debate is on a chapter by chapter basis, and only a very sketchy attempt is made to draw the common threads together in the preface. This is a serious shortcoming, because the contributions do vary a great deal in quality, scope, methodology, and in their conclusions. The most useful paper is Bert Hickman's elegant survey of econometric models, while the least informative are those by Nove on the Soviet Union and by Dow on France, Germany and Italy. Only a few authors put the post-war cycle in its long-term historical context, and in this respect Professor Matthews's paper on Britain is one of the best. The methods used to measure the amplitude of cycles and date their turning points vary considerably, and it is a pity that some effort was not made to achieve a greater degree of uniformity in this matter. Rather surprisingly, there is no specific paper dealing with the transmission of cycles among developed countries—a rather serious omission in view of the fact that it would have helped to clarify the issue of the relative mildness of the post-war cycle. Fortunately, an excellent chapter by Kurt Rothschild on Austria and Switzerland, a title which somewhat belies the wider context in which it is set, helps to repair this gap to some extent.

Perhaps the chief defect of the volume stems from the fact that the authors have been too concerned with presenting the facts and relating these to the conference title, to the ultimate neglect of analysing the reasons for the changes in cyclical characteristics in the post-war period. Nevertheless, the work as a whole provides a useful insight into the type of business cycle research now in progress.

DEREK H. ALDCROFT

URBAN DEVELOPMENT

Developing Patterns of Urbanization

Edited by Peter Cowan. (Centre for Environmental Studies.) Pp. vi+216. (Oliver and Boyd: Edinburgh, February 1970.) 40*s*.

Economic, social and physical development is proceeding so fast now that the importance of forecasting the future is being understood to an increasing extent. This volume contains an attempt by a group of specialists in fields related to urbanization to explore to what extent guidance can be given in this subject by a forecast of possible future developments. This has resulted in a collection of essays which, according to one contributor, "amounts to a lightly disciplined exercise in intuitive thinking; hopefully the next phase will introduce greater rigour and sharper purpose" (D. Bayliss). This is a somewhat modest statement, underestimating perhaps the significance of fascinating and thought provoking contributions. To forecast the future is indeed a difficult task, and it is not surprising that a group of distinguished writers does not necessarily reach a consensus of opinion; it may be judged in fact to be one of the merits of the essays that the reader is presented with differing alternatives, and so encouraged, if he is interested in and concerned with urban problems, to evolve his own interpretations.

It seems very likely that the broad pattern of urbanization, which has not been changed much in the geographic sense during the past 50 or even 500 years, will look not so very different in AD 2000, existing investment in the built environment being a compelling constraint (E. Jones and P. A. Stone). Besides, people are not prepared to spend as much on housing as they do, for instance, on motoring, and may well favour a greater output of restored and reconditioned dwellings which can be produced quicker and cheaper and will therefore command lower rents. In any case, there are doubts as to whether the space economy practised since the Second World War has produced housing which will be sufficiently adaptable for future needs; the oldest section of the housing stock will probably not be the first social slums of the near future (C. Price). But the expected population growth cannot be accommodated entirely in existing cities, nor, with some exceptions, in self contained new cities: it will have to be retained in the suburban ring of existing metropolitan areas (P. Hall). Such a pattern will meet the clear demand for more space both near the home and in a not too distant countryside; it will permit central decongestion and follow well established trends of decentralization along fast transportation radials on a regional scale and perhaps reconcentration at the local suburban scale. Such a trend may be accelerated by developing traffic technology, increasing speeds and improved telecommunications (P. Cowan).

Considerable changes in life styles and activities can take place, however, without a change in the physical pattern of our urban areas. There seems to be a growing popularity of family life related to a shift towards the home and marriage partnership. More people, including skilled and unskilled manual workers, buy their own homes. People get married much earlier, which means that their grown up children will leave them on their own for very much longer periods than was the case in earlier generations (P. Wilmot). But, whereas at the child rearing age suburban homes may be preferred, at the subsequent stage a central home with ready access to work for the wife may be preferred. Many families in central areas would like a second home in the country; could it be that the home in the central area could become the second home with a family base in the suburb or in the country? (A. Price). Will the coloured population be permitted an adequate place in the evolving pattern? (N. Deakin). Provision for recreation will be an issue of increasing importance (B. Rodgers). Leisure activities are more likely to be affected by developing life styles rather than by income or working hours; as is well known, many work overtime or take second jobs. But will it be necessary to invent "pseudo work" as a leisure activity? (D. Bayliss). It is a strange belief in our society that western man must always be active; we pay lip service to the civilizations of the East, but can we not learn from them: contemplation?

Finally, there are some important comments on the approach to "planning" itself. Goals should be precisely articulated and should be subject to public debate (A. G. Wilson). The relation between the planners and the planned may well become one of the most crucial and decisive questions during the next few decades (P. Cowan). All the contributors seem to have accepted as unalterable the considerable population growth forecast for the end of the century; but one would like to think that a limitation of population growth in the interest of the community as a whole could also become an important political issue.

It is the aim of a reviewer of a deserving work to stimulate the interest of the readers; I hope I have succeeded in doing so.

V. Z. NEWCOMBE

WHAT IS CYBERNETICS?

Survey of Cybernetics

(A Tribute to Dr Norbert Wiener.) Edited by J. Rose. Pp. xi + 391. (Iliffe: London, January 1970.) 105*s*.

ONE of the contributors to this book writes aptly, "We have covered a great deal of ground and have done it rather unevenly". Although to the editor of the book, Wiener's contribution to cybernetics stands supreme, it is Wiener's definition which makes another contributor ask, "What is cybernetics? Or rather, what is it not?"

Boulanger claims that Ashby's homeostat foreshadows the future auto-pilot. Surely, any such random-trial, non-learning machine would crash most planes? But to overlook completely the features of randomness and probability in robots, as do some of the contributors, would seem to be just as wrong as making them paramount.

Several contributors concentrate on the listing of definitions. Perhaps this is useful, but should not practical results come first? As Walter states, "This peculiar gap between theory and practice is a feature of cybernetics". One welcomes Walter's criticism of Wiener, because it is only with the spread of such a critical attitude that further progress can be expected.

Clark's review of medical cybernetics is most useful, but Rosie's chapter on information theory seems rather out of place. At last, after fifteen years of secrecy, Pask publishes some details of his early work on learning matrices, but by now this is of historical importance only.

Apter suggests that his particular segment of the field should become more central to cybernetics, in spite of its deterministic, non-probabilistic nature. Leondes and Mendel review artificial intelligence control, but admit that the widely used single linear threshold element is "off-line". Should not then the cybernetic validity of all such work be questioned, because clearly any animal learning system must always be "on-line"?

The editor of the book seeks to eliminate the fragmentation of scientific thought and activity. But is it not this very fragmentation which has, in the past, produced scientific progress? Do we really want to impose a somewhat totalitarian structure on technology, by such steps as "The reduction of the numbers of technological societies"? What is really needed to unify the technologies, the editor writes, is a common cybernetic basis.

Surely, it is important not to ignore the fact that if we allow any attempt by any national, or worse still by any new international, body to impose any such unification, then scientific progress is likely to cease, for progress implies freedom and the absence of regimentation.

This book has helped to confirm the suspicion that between those who actually pursue active research work in practical cybernetics, and those who merely write and talk about it, there is a widening barrier. For we are told in the book that it is cybernetics which "would forge various disciplines into a unit that is part of the human search for truth and for understanding of man's place in society".

One would suggest humbly that there is no need to apply the name of cybernetics to this, because a more suitable name is in existence. The process is more usually simply called "science".

JOHN F. YOUNG

CELL TO CELL MESSAGES

Mediators of Cellular Immunity

Proceedings of an International Conference held at Brook Lodge, Augusta, Michigan, April 28–30, 1969. Edited by H. Sherwood Lawrence and Maurice Landy. (Perspectives in Immunology: a Series of Publications based on Symposia.) Pp. xv + 469. (Academic Press: New York and London, December 1969.) 89*s*.

MUCH the most profitable kind of meeting for furthering an area of experimentation is one restricted to about thirty expert participants who have no closely set programme. A volume compiled from prewritten pieces is then quite inappropriate and is a custom that increasingly discourages attendance at symposia. The present volume is the best answer found so far for conveying the resulting wisdom to those not fortunate enough to have been invited, and whose very numbers in attendance would have inhibited the searching discussions and criticisms that are of such value.

This book is essential reading for all immunologists, mentally indigestible though it is. The many criticisms as a readable book must be excused by what it achieves, even its typographical errors by its speed of publication. The confused state of the subject is the reason for its choice and it can be likened to a detective novel where clues are overabundant, some false, but at the end the criminals are not brought to trial. Thus there is no summary; you read it all or you do not read it.

It is astonishing that a free ranging discussion can lead to such a good overall sequence; in this respect it is an improvement on the first volume of the series and reflects admirably upon chairmen and speakers alike. The whole content is alive and complex; Dr X ends a piece with ". . . I don't know if that answers your question". Dr Y replies "I am not sure either. . .". References are provided sparsely in some parts of the text, other parts could profitably have included as many.

I submit that for conveying the gist of the content this is a particularly difficult kind of volume to deal with. There are six sessions reported verbatim, each excellently introduced by a speaker who seeds the congregation with chips from the particular axe he grinds. In the last 18 pages chairmen attempt to summarize their sessions, but this is disappointing; it is not summarizable material. Particularly interesting discussions cover the following important areas. Session one, events preceding the appearance of blast cells when lymphocytes are stimulated *in vitro*; the commitment of 1 to 2 per cent of a cell population in cell mediated immunity is compared with a maximum of 0·01 per cent of cells destined to secrete antibody. Only the latter figure is consistent with clonal selection, some form of which most immunologists would like to settle for. Session two includes the hypothetical nonsecretable IgX that, if it exists, would bring recognition for cellular immunity in line with that for humoral responses; cell co-operation in thymus dependent populations and the role of non-thymus dependent lymphocytes and of macrophages are discussed. Session three has all the data on transfer factor that is below 10,000 molecular weight but seems to transfer specific cellular responsiveness between individuals. Is it some kind of immunogen or do we not yet have a pigeonhole to file a molecule like that ? It can now be compared with the "factors" discussed in sessions four and five that are released from stimulated cells *in vitro*. There may be seven (migration inhibitory, lymphotoxic, skin-reactive, chemotactic, mitogenic, plus interferon and antibody), but we may hope that apparent differences may reflect the different test systems used and there may be fewer. Finally, session six considers the difficulty of having a foolproof surveillance system that would distinguish between an unwanted tumour cell and a self + X entity leading to self damage arising from delayed hypersensitivity.

The overall result is a sorting out of what evidence is conflicting, what are crucial points to establish, what alternative interpretations might be put on results that conflict with the most plausible hypotheses, and what weak points can be discerned in the defences where best to apply renewed experimental pressure.

D. A. L. DAVIES

ACTION OF ANALOGUES

Analogues of Nucleic Acid Components

Mechanisms of Action. By P. Roy-Burman. (Recent Results in Cancer Research, Vol. 25.) Pp. xi+111. (Springer-Verlag: Berlin and New York, 1970.) 28 DM; $7.70.

DURING the past twenty years large numbers of analogues of purine and pyrimidine derivatives have been synthesized as compounds of potential therapeutic value and there has been a large volume of research effort devoted to elucidating the biological activity, metabolism and molecular modes of action of these substances. The results of these researches are scattered widely throughout the literature and this monograph is of value in that a large amount of information has been assembled and condensed by the author into a single slim volume.

The book includes brief, but well illustrated, summaries of the biosynthesis and degradation of purine and pyrimidine nucleotides. A representative selection of the more important purine and pyrimidine analogues is considered, and in each case the evidence relating to the metabolism of the compound, its effect upon enzyme systems and, where appropriate, the consequences of its incorporation into nucleic acids are reviewed briefly.

The author has managed to condense a great deal of information into a remarkably small amount of space. While the presentation is somewhat concentrated, it is fully documented and well supported with diagrams illustrating on the one hand the metabolism of the analogues and on the other the reactions with which they, or their metabolic derivatives, interfere. This compilation will be a useful source of information to many scientists in the field of cancer therapy and to those with more general interests in the area of nucleotide and nucleic acid biosynthesis and metabolism.

While the circulation of a highly specialized publication such as this will inevitably be small, it is unfortunate that it should have been so highly priced. At a more modest figure the book might have been attractive to many individual purchasers and would certainly have been much better value for money.

R. M. S. SMELLIE

ESSAYS ON BOTANY

Cellular Differentiation in Plants and other Essays

By C. W. Wardlaw. Pp. 160. (Manchester University Press: Manchester; Barnes and Noble: New York, March 1970.) 40*s*.

FOR fifty years Professor Wardlaw has been a keen student of plant morphology and morphogenesis. Readers of his previous books, such as *Phylogeny and Morphogenesis*, *Embryogenesis in Plants*, and more recently (1965) *Organization and Evolution in Plants*, will be familiar with his interests, as well as his predilection for the philosophical aspects of biologic organization. This new book is a collection of five essays, or "emeritus excogitations", in Wardlaw's phraseology, written in the past few years on subjects dear to his heart. In one of the essays Professor Wardlaw tells of the reception his *Organization and Evolution in Plants* received at the hands of the critics: "there was one sapient chap who indicated that I had explained very little and that all I had given my readers was words". I imagine that that same reviewer would have said something similar about this book. But yet, there are still challenging questions in plant morphogenesis that lie along "the dangerous, jungly pathways which I, in my still youthlike enthusiasm, feel impelled to tread", and we, the readers, should follow —at least a little way.

This book is not for the impatient reader after hard, clear facts; nor is it a propaedeutic book easily accessible for the interested beginner, as the dust-cover rubric states; rather, it is for one familiar, and preferably in empathy, with Wardlaw's earlier writings. The longest essay of the book, entitled "Aspects of Cellular Differentiation", is in two parts. The first gives us a historical perspective of the subject, reminding us that the current view relating a cell and its milieu to the developmental pathway it will take, was anticipated by the botanists of old (Grew, Vöchting, Driesch). The second part considers modern aspects of differentiation. Here Wardlaw relies largely on Bonner's book *The Molecular Biology of Development* for his attempt to see how far molecular biology can be profitably used to interpret morphogenesis and epigenesis.

If cell differentiation is "one of the most important, beguiling, provoking and difficult themes in botany" then what of epigenesis, the topic of the fourth essay ? It is "just plain enigmatic". Enigmas arise out of ignorance: we need to think more deeply, more clearly, or in new directions if they are to be dispelled. But in which direction ? For instance, if we seek the aid of the molecular biologist should he be concerned with the chemistry of atoms and electrons or with macro and megamolecules ? Wardlaw recognizes the challenge but does not give any guidance or new ideas. Some may think that he deliberately invokes obscurity by introducing into his thesis the intangible Aristotelian concept of entelechy, and by speaking of "the deep inwardness of cells during their growth and development . . . that makes our understanding of them more and more remote", as well as by injecting a touch of unorthodoxy by mentioning that cells may transcend their genetic potentialities in creating neoformations.

Perhaps the most successful essay is the third, "Reconciliations among Apex Lovers". Wardlaw attempts to resolve rival points of view about the structure and function of shoot apical meristems that still prevail. His criteria for reconciliation are nothing more than the call for scientific objectivity and it seems an unfortunate reflection on those working in this field that their conflict of views attracts an essay of this kind.

Professor Wardlaw's style of writing is unique. It is difficult to decide whether it is unforced literariness, or whether he writes with Robin Goodfellow at his elbow. If the former, the product is eccentric and the effect is irritating; if the latter, then the following passage from the first essay "On Writing Botanical Essays" is a gem of self-parody: "When I was a mere botanical neophyte, in the early spring sunshine of promise, in fact at the ripe old age of twenty, every new volume that my revered Professor commended to me and, indeed, was often kind enough to put into my hands, seemed to me to exhale a rare, exotic perfume, a distilled fragrance, nay ! the very elixir of true learning". If the botanical neophytes of today, as well as those of maturer years, can grope through the exotic perfumes exhaled by this book they will find something. But that something they will probably have thought of for themselves or have read elsewhere, at less length, in books of more substance.

PETER BARLOW

TRIBUTE TO A BOTANIST

J. Sen Memorial Volume

Edited by H. Santapau, A. K. Ghosh, S. K. Roy, S. Chanda and S. K. Chaudhuri. Pp. xxi + 498. (J. Sen Memorial Committee and Botanical Society of Bengal: Calcutta, 1969.) Rs. 40; $10.

INDIA has had the misfortune to lose several of its distinguished botanists in the prime of life. Birbal Sahni, FRS, died before he was 58; P. Maheshwari, FRS, soon after 60; and Jitendrakumar Sen, deputy director of the Botanical Survey of India, died in December 1966 at the cruelly premature age of 45.

This book, published to perpetuate Sen's memory, begins with a tribute from John Walton, Emeritus Professor of botany in the University of Glasgow, followed by a short biography provided by Dr Sunirmal Chanda, Bose Research Institute, Calcutta. Dr Sen's publications are then listed, sixty-eight in twenty-three years, testifying to his industry. His contributions lay chiefly in the fields of palynology, palaeobotany and wood histology, later turning to horticulture. Appropriately, the fifty-eight articles making up the bulk of the volume are grouped into four sections: palaeopalynology, palynology (Recent), palaeobotany and taxonomy and other topics.

Sixteen papers on palaeopalynology, chiefly from Indian authors, describe spores or pollen from the Cambrian to the Quaternary. A. K. Ghosh and A. Bose record "vascular microfossils" from North American Cambrian rock samples supplied by Professor B. F. Howell of Princeton University. The authors provide no illustrations. Without these it is difficult to evaluate their claim that "it is obvious that the vascular plants had an origin long before the Silurian period". G. O. W. Kremp and J. G. Methvin discuss the increasing problems of data retrieval in palynological research and suggest that the application of computer techniques can save the situation and promote fruitful research on a world scale.

The section on Recent palynology has seven contributions: one by G. Erdtman and A. Dunbar on the fine structure of *Macrozamia* pollen, the rest by Indian contributors on the pollen of Scrophulariaceae, Casuarinaceae, Gardeniaceae and Sterculiaceae, and on Indian fern spores.

Of the twenty-one palaeobotanical papers, eighteen are by Indian authors and most of these deal with floras or individual taxa ranging from the Lower Gondwanas of India to the Tertiary. Of particular interest here is Manju Banerjee's paper on *Senotheca*, a new fructification, associated with leaves of *Glossopteris taeniopteroides* Feistmantel, from which cuticularized seeds were obtained by maceration. In the same section Emeritus Professor Tom M. Harris discusses the problems of naming Jurassic conifers and Dr Edna Plumstead reflects on the earliest plant life.

The last section has fourteen papers, all by Indian authors. Subjects covered include cytology, chemotaxonomy and pharmacognosy applied to taxonomy, systematics of various Indian plants, floristics, conifer wood structure, and lastly an account of the Dehra Dun Herbarium by Professor Emeritus M. B. Raizada.

The book is set in easily readable type and cleanly printed on rather poor quality greyish paper. There are commendably few printing errors. Text-figures are excellent, but some of the plates are poor, notably those between pages 152–153 and 208–209, where alternating dark and light vertical bands make it difficult to understand spore ornamentation. Apart from these small technical blemishes, the book is a praiseworthy production and a fitting tribute to one who did much in a short working life to advance the cause of Indian botany.

WILLIAM S. LACEY

SPIDERS, SCORPIONS AND MITES

The Arachnids

An Introduction. By Keith R. Snow. Pp. 84. (Routledge and Kegan Paul: London, April 1970.) 25*s* boards; 14*s* paper.

THE word Arachnida has recently appeared in the syllabuses of several examining boards, and this book is a timely response to the need for more information than is contained in the ordinary textbooks.

An introductory chapter describes the general structure, outlines the physiology of the class, and ends with short diagnoses of the six orders chosen for fuller treatment. First place is then given to the Acari, which are scarcely typical arachnids, but which occupy twenty pages, or a quarter of the whole. Perhaps the economic importance of ticks and mites is held to justify this proportion. Spiders and scorpions together account for another quarter.

Dr Snow has kept prominently in mind the needs of examination candidates, and this may be taken to explain the meagre space given to the other orders. A better balance might have been obtained by shortening the glossary: readers for whom this book is meant should not need definitions of such words as lateral, marine and prey, and many others. But compression was essential, and is regrettable only when particular statements appear to be generalizations. Obviously, exceptions cannot often be mentioned, but the implication that all spiders' webs are orb-webs should have been avoided. There are a few mistakes: for example, Fig. 18 gives a spider four lung-books, and the remark that harvestmen mate two or three times a season is an understatement of their remarkable promiscuity.

Some readers will be surprised and others pleased at the inclusion of *Limulus*, an animal which, though not a true arachnid, can undoubtedly teach us much that has not yet been learned from its study. Many, too, will appreciate the advice on fieldwork and laboratory methods.

A word of praise is due to the illustrations, admirable line drawings that show precisely all details of structure. The book, in fact, is successful as just what it set out to be—not a monograph, but a helpful introduction to a group that is beginning to receive that appreciation it has always deserved.

THEODORE SAVORY

ADRENAL PATHOLOGY

Functional Pathology of the Human Adrenal Gland

By Thomas Symington. Pp. xvi + 551. (Livingstone: Edinburgh and London, 1969.) 200*s*.

THIS book contains a wealth of information about the adrenal gland as is only to be expected from its chief author, Professor T. Symington. He states that he has tried to avoid the temptation to produce just another book with a descriptive catalogue of the pathology of the adrenal gland but to produce a more dynamic approach to adrenal disease based on the knowledge of normal structure and function. In my opinion he has certainly succeeded.

The book commences with a very large section on the adrenal cortex, describing features of the foetal, neonatal, infant and adult stages of this gland. The biosynthesis and metabolism of steroids are discussed, and the physiology and pathology of the cortex both in health and disease are more than adequately covered. Technical and chemical methods used for the investigations of disorders of the gland are also given. I am pleased to see that the author aptly points out that investigations of the biosynthetic ability of adrenal tissue by radiochemical incubation studies *in vitro* need not reflect what is happening *in vivo*. More *in vivo* studies should certainly be made where possible.

The next section of the book deals with the adrenal medulla by A. M. Neville and again the same pattern of describing the foetal and adult gland followed by the biochemistry, physiology and pathology is followed as for the cortex section. An excellent chapter on the detection and measurement of catecholamines in tissues and body fluids ends this section.

A section on the chemoreceptor system follows. At first this might seem to be out of context in a book about the adrenal gland, but the demonstration of catecholamines in the normal carotid body and in some tumours arising from it together with the possible neuroectodermal contribution to its development serves, I suppose, to emphasize the close relationship between the chemoreceptor and chromaffin systems.

A remarkable section devoted to an atlas of human adrenal cortex ultrastructure by A. MacKay now follows. This atlas, which is divided into three parts, gives well detailed electron micrographs of the three zones of the normal human cortex, then micrographs of the pathological human adrenal, and finally details of the processing techniques are given. Altogether more than a hundred micrographs are presented, which makes the book rather unique. Much of our present knowledge of steroid biosynthesis has been acquired from tissue slices or homogenates of normal and abnormal adrenals, and the electron microscope shows that all such preparations have a much greater structural heterogeneity than had been suspected by light microscopy. While the cells involved in normal and abnormal steroid biosynthesis have, however, been better characterized, many problems on the correlation of structure and function of the adrenal cell still exist. It is nice to see that the major drawbacks of interpreting the electron micrographical data are pointed out.

The book finishes with a short section on the metabolic and hormonal response of the body to injury.

This book, though intended primarily for pathologists, will interest biochemists and endocrinologists. It seems rather expensive, but with its 550 pages with its excellent atlas of human cortex ultrastructure I believe it to be well worth the money. D. EXLEY

DECOMPRESSION SICKNESS

Subatmospheric Decompression Sickness in Man

By D. I. Fryer. (AGARDograph No. 125.) Pp. 343. (Technivision: Slough, 1969.) 145*s*.

IT is surprising to hear that in spite of all the advances in aircraft technology resulting in the provision of reliable pressure cabins and operational pressure suits, the hazards to man of subatmospheric decompression sickness have not decreased.

This book admirably illustrates the value of taking a critical overall look at a subject. It gets the problems into perspective and in this case reveals how fragmentary our knowledge is.

In an effort to determine precisely where we are in our understanding of subatmospheric decompression sickness the author, who is a serving medical officer in the Royal Air Force, has assessed with remarkable perception a multitude of papers which have been written on this subject. In his evaluations he has made extensive use of his own practical experience and experimental observations. It is clear that we undoubtedly possess a lot of knowledge about decompression sickness but very little understanding, and the author rightly comes to the disappointing conclusion that "there can be few subjects as frustrating as that of subatmospheric decompression sickness, for its manifestations are so protean, its mechanisms so obscure and its prevention so difficult in practice".

For those who may wish to take up the challenge and to give serious consideration to this intriguing problem there is a wealth of informed opinion in this book and an excellent bibliography of more than 450 references.

D. N. WALDER

JOINT ACTION

Lubrication and Wear in Joints

Edited by Verna Wright. (Proceedings of a Symposium organized by the Biological Engineering Society and held at the General Infirmary, Leeds, on April 17, 1969.) Pp. 152. (Sector: London, March 1970. Distributed in the USA and Canada and South America by J. B. Lippincott.) 53*s*.

THIS collection of papers delivered at a symposium held about a year ago represents the thinking at that time of research groups, chiefly in the United Kingdom, on the subject of lubrication of diarthrodial joints. The newest theory, that of "trapped pool" lubrication, is given the greatest coverage. Observations on the structure of articular cartilage as interpreted by electron scanning are reported in some detail and excellent illustrations are provided in support. Those who support other theories of lubrication also had their say, both positively and, through the discussion, in challenging the validity of the data on which the trapped pool theory is based. A contribution on artificial lubricants, the last chapter, is spoiled by the omission of the table of criteria which a lubricant should fulfil before it could be used in an animal joint. Nor is there any evidence to support the premise that artificial lubricants could halt the disintegration of articular cartilage once fibrillation is established in weight-bearing areas.

The chapter on joint disease and the causation of osteoarthritis is disappointing in that it presents a standard list of causes which has been in use for many years and does not indicate that any new thinking about the subject is being indulged in by any of the groups represented at the meeting. There were no contributions dealing with the subject of wear of articular cartilage, but the impression is left that "wearing out" of cartilage as a purely mechanical process can be an important cause of osteoarthritis. It is evident from these papers that bioengineering research groups should have one member who is a biologist. Although the discussions applied some correctives there is no substitute for a built-in stabilizer.

Chapters are also devoted to joint prostheses and joint simulators—the problem of wear is a very real one when dealing with joint prostheses.

Elegant analyses of the forces acting on the hip and knee are presented by Paul. This work is the best dynamics study of joint forces so far available and must be required reading for everybody interested in joint function. We must also learn the lesson that the magnitude of force changes rapidly when the normal person is ambulant and is not accurately simulated by many of the compression studies carried out on cartilage to date.

As a deliberate policy an index has been dispensed with and bold marginal sub-headings have been used to indicate important topics. This has produced an attractive arrangement for reading, but the reason for choosing some of the subheadings is not clear, and an index would have improved the presentation. To compensate, there is an extensive list of pertinent references in an appendix. Photographs and diagrams are excellent throughout.

As is true for most symposia records, this one will be of most value for those wishing to become acquainted quickly with the principal lines of investigation. Clinicians and biologists will probably derive most benefit, while engineers may conclude that there is still a lot to be learnt about the physiology of diarthrodial joints.

C. G. Woods

NEW NUCLEAR TEXT

Nuclear Electronics

By E. Kowalski. Pp. x402. (Springer-Verlag: Berlin New York, 1970) 96 DM; $26.40.

I used to start my courses on electronics by ritually smashing a valve with a hammer. I don't do it now because there was always a slight danger in the procedure and the message about transistors has reached all but the most reactionary quarters. If, and it must be said that the style, presentation and general quality of production are a formidable inhibitory influence, one were to extend the principle to the work by Dr. Kowalski, there would be little to do for the book is up-to-date and illustrates most of the techniques with diagrams showing integrated circuits or transistors.

The author starts by giving the theoretical background to radiation detectors but in this, as in the work as a whole, he fully illustrates the argument with circuit diagrams. In the introduction he had made the point that it is never too soon to get away from the vagaries of analogue circuits into the sweet certainty of digital representation and in the middle section he makes much of the tools, both technical and mathematical by which the transformation may be accomplished. The last section of the work contains a comprehensive review of digital techniques complete with a note on Boolean algebra.

As small digital computers are changing the approach to the problem of processing digital information at the same frenic rate that transisters have changed the methods and scope of instrumentation, it would be churlish to complain that the section on them is too short, particularly in view of the quality of the background information on digital circuits in general. Nevertheless it is possible to see that this section should, in future editions, be enlarged.

It is stated in the preface that one of the aims of the text is that it should be useful as a reference work in years to come and the extensive references must alone make this a strong possibility. The list includes more than 900 entries most of which have been published within the last three or four years. Altogether the book is to be recommended as an important and timely addition to the literature of the subject.

Lindsay Molyneux

This review has been set by the combination of a 'Micro 16' computer (Digico Ltd) directly interfaced with the photo-unit of a 'Linotron 505' typesetting machine. The computer, as well as deciding the line endings and adjusting the spaces for justification, also simulated the functions of the logic unit of the 505. Because the first proof (set in 39 seconds) contained an error, a second proof was made using the ADDATAPE correction system; this took 44 seconds. The programs and interface were developed by Dr Molyneux in the School of Physics, University of Newcastle upon Tyne, during a Ministry of Technology Computer Typesetting Research Contract.

ORGANIC CHEMISTRY REVIEWS

Topics in Carbocyclic Chemistry

Vol. 1. Edited by D. Lloyd. Pp. xi+373. (Logos Press, in association with Elek Books: London, 1969.) 125*s*.

In recent years an increasing number of publications devoted to reviewing specific areas of organic chemistry has appeared. These are, on the whole, welcomed by organic chemists because they relieve to some extent the ever-growing burden of the original literature. This book is the first of a series which is to provide reviews in the field of carbocyclic chemistry. The series is entitled "Topics" rather than "Advances" because the articles are intended to "present the subject with sufficient background to make them acceptable to all readers". In my opinion this distinction is somewhat pedantic because most comprehensive reviews, even of the recent literature, would more or less satisfy this demand.

The necessity for a publication of this type is also debatable because its usefulness to a particular chemist will be severely limited by the enormous scope of the field of carbocyclic chemistry. Of the articles in the current volume, that on the benzidine rearrangement, for example, could easily have found a place in *Advances in Physical Organic Chemistry*, and that on bicyclo[3.3.1]nonanes would have been suitable for *Advances in Alicyclic Chemistry*.

Aside from this carping, the book, which is excellently produced, will be a valuable addition to any chemical library. The standard of the individual articles is high and they mostly cover the literature up to 1968 with more recent work in addenda. D. V. Banthorpe in "The Benzidine Rearrangement" provides a comprehensive and critical account of this problem which has now beset chemists for more than a hundred years. D. H. G. Crout, in "The Biosynthesis of Carbocyclic Compounds", has performed the difficult task of compressing a vast amount of material into an intelligible account. Of necessity there are various incursions into the domain of heterocyclic chemistry. G. L. Buchanan, in "Bicyclo[3.3.1]-nonanes and Related Compounds", entertains the reader to a lucid account of these interesting systems, and D. M. G. Lloyd provides a short article on "Feist's Acid".

H. P. Figeys, in an article entitled "Electronic Structure and Spectral Properties of Annulenes and Related Compounds", presents a critique of the theoretical chemistry of the annulenes which is both readable and intelligible to the experimental organic chemist. Particular attention is devoted to antiaromaticity as is merited by recent interest in this area. Breslow's speculations on the fusion of two 4n systems are dismissed as "two wrongs do not make a right". Much discussion is devoted to the red herring of benzo-annelated systems whereas the annulenyl and annulenium ions are unfortunately entirely omitted.

M. V. Sargent

REFRACTORY METALS

Properties of Refractory Metals

By Walter D. Wilkinson. Pp. x+355. (Gordon and Breach: New York and London, November 1969.) $33; 275*s*.

The text of this book was completed in May 1967 (but not published until November 1969) under the direction of the American Society for Metals on behalf of the United States Atomic Energy Commission. It is consequently a book on refractory metals for use in nuclear reactors and covers vanadium, chromium, niobium, molybdenum, tantalum and tungsten. A somewhat pedantic choice of a lower melting limit of 1,855° C for deciding the metals to be discussed results in the exclusion of zirconium (m.p. 1,852° C) and the inclusion of chromium (m.p. 1,875° C). This seems to be straining to rationalize a choice that could otherwise have been made straightforwardly and, by omitting zirconium, it results in the book being less useful to technologists in the nuclear power field than it need have been. Although this is a minor point, it does seem to reflect the author's approach to his task, which is an uneasy attempt to combine the academic (with its aridity for the practical man) with the practical (with its more than occasional fatuity for the high flown academic).

The author has his academic fling in the first five chapters in which there has been some hard work to squeeze generalizations from the plethora of experimental data on these metals. The first chapter is called "Atoms, Electrons and Fabricative Properties", and, as might be expected, is an odd mixture. After pages which deal *inter alia* with *d*-electrons, N(E)–E curves, bandwidths and Bragg disordering energy, we come down to earth with "proper thermal conductivity is essential for any material used as cladding or jacketing* for nuclear fuels". While wondering what "proper" thermal conductivity is, the reader's eye seeks the asterisked footnote, to be told "cladding" is a coating or layer of metal metallurgically bonded to a substratum. " 'Jacketing' (often called 'cladding' in the nuclear energy field) is sheathing that is not metallurgically bonded" (p. 25). Such a combination of the slipshod with the trivial reduces faith in much of the remainder which, being a recital of experimental facts, must be taken at its face value.

The next four chapters are on "Corrosion, Compatibility and Protective Coatings", "Interstitials and their Effect on Properties", "Ductility and Brittleness" and "Mechanical and Deformation Characteristics".

Two chapters are then devoted respectively to the tantalum and tungsten group metals. The final chapter is on heat treatment. Each of these contains more information of the sort presented in the earlier chapters but with less of the academic fluff.

To me, the book appears as an inappropriately organized and indigestible presentation of detailed experimental data. It is an expensive buy which could have benefited from a tough and critical editor. J. G. BALL

REACTOR PHYSICS

Experimental Neutron Thermalisation

By P. A. Egelstaff and M. J. Poole. With a Mathematical Appendix by P. Schofield. (International Series of Monographs in Nuclear Energy, Vol. 106.) Pp. ix + 399. (Pergamon: Oxford, London and New York, September 1969.) 130*s*; $17.50.

THE scale of investment in nuclear power already dwarfs that in almost every other science based industry, and will presumably increase very rapidly for some decades, unless there is a sudden breakthrough in fusion technology. It is estimated that the market for uranium ore alone will be worth more than $1,000 million yearly by the mid-1970s, and there is an obvious incentive to make the best use of this valuable material. On this scale, even apparently insignificant improvements in the accuracy of reactor core physics calculations can lead to very large financial savings. Basic to these calculations is an understanding of the physics of neutron scattering and thermalization in the most common reactor materials, and in this area considerable progress has been made in recent years, chiefly by groups working at the large national laboratories. Much of this work has been presented at IAEA conferences or in report form, and perhaps the major contribution of this book is to bring together the most significant elements of this material in a more readily digestible form. The authors have been responsible for many important advances in this field over a number of years, and the book can be regarded as an authoritative statement of progress up to 1968, which is the latest date on the referenced material.

The first three chapters are devoted to a rather brief development of the basic theory of neutron scattering in condensed matter, and to the analysis of theoretical models for the spectral density in various moderator materials. Chapter four covers the experimental techniques available for the production of neutrons of specified energy, and for the measurement of the energies of scattered neutrons. This is followed by an account of the application of these techniques in the measurement of scattering cross-sections, and by three chapters which discuss the analysis and interpretation of the resulting data. The second half of the book is given over to a description of techniques developed for the measurement of neutron energy spectra in moderators and reactor lattices, and to a detailed review of the results obtained by these means. Some of the methods used in the calculation of neutron energy spectra are discussed at greater length in an appendix.

In general the book is well written and the material is presented and discussed in logical sequence. It will undoubtedly be of considerable value to every worker in the field and to anybody involved with reactor physics calculations. It could also be recommended to students coming fresh to the subject, with the reservation that they should seek elsewhere for the material covered in chapters one and four.

At first glance the book is well produced, but detailed reading of some sections reveals an unfortunate incidence of misprints; where these arise in the text the meaning is usually clear, but in several instances the errors in equations lead to undue confusion in reading the associated text. In any future edition of this useful book some attention might be given to proof-reading.

The neutron chopper depicted schematically on the jacket would seem to have some useful properties.

J. SCOBIE

GRAVITATIONAL OBSERVATIONS

Gravitation and the Universe

By Robert H. Dicke. (Jayne Lectures for 1969. Memoirs of the American Philosophical Society, Vol. 78.) Pp. xvi + 82. (American Philosophical Society: Philadelphia, 1970.) $2.50.

BEFORE 1969, the last occasion on which the Jayne Lectures of the American Philosophical Society were devoted to a topic in the physical sciences was in 1965, when Professor William A. Fowler gave his notable series of talks on nuclear astrophysics. Last year, it was again the turn of astronomy to provide the subject for the Jayne Lectures, when Professor R. H. Dicke discussed "Gravitation and the Universe", and his three lectures have now been published in monograph form. Dicke discusses the problems inherent in any attempt to distinguish between Einstein's theory of gravitation and the scalar–tensor theory of which he is a major proponent, the first lecture being devoted to the Eötvös experiment as an example of laboratory tests of both theories, the second discussing the possible contribution of solar oblateness to the many perturbations of Mercury's orbit, and the third dealing with cosmological effects and the significance of the "3° K" background radiation.

Laboratory tests cannot distinguish between the predicted effects of the two theories, but provide solid evidence in support of both. Also, as Dicke sums up, although the scalar–tensor theory could provide a key to our interpretation of observations of the "cosmic fireball" if there were other strong evidence in favour of the theory, it is doubtful that "observations of the cosmic fireball will ever supply the essential element needed for the confirmation or rejection of the scalar–tensor theory". The issue here is further confused by the recent observations (not discussed by Dicke) suggesting that the background radiation may be "grey" rather than "black", so that the question of solar oblateness and the real magnitude of the residue in the perihelion rotation of Mercury is at present of overriding significance as a test to distinguish between the two theories, although sufficiently accurate measurements of the gravitational bending of light may shortly provide an independent test. There is no attempt to gloss over the difficulties involved with each kind of experiment, although naturally Dicke is not an unbiased reporter, and this book provides a useful insight into the way in which cosmologists, solar astronomers and laboratory physicists can all contribute to an investigation of the gravitational interaction.

Suitable for the non-specialist or student rather than those working directly on these problems, the monograph is excellent value, being lavishly illustrated and generally well produced apart from a few minor misprints.

JOHN GRIBBIN

Obituaries

Dr D. F. Martyn

THE death of David Forbes Martyn on March 6 has removed a pioneer of research on the upper atmosphere and a leader of Australian science. He was born on June 17, 1906, in Cambuslang, Scotland, the son of Dr Somerville Martyn. His early education at Plymouth College and Allan Glen's School was followed by a period at the Royal College of Science, London, from which he graduated BSc, ARCSc, in 1926. He took his PhD in 1929, and in 1936 was awarded the degree of DSc by the University of London. He was Houldsworth Fellow of the University of Glasgow from 1927 to 1929.

In 1929 Martyn moved to Australia, to a post with the Radio Research Board, which was attached to Mount Stromlo Observatory, Canberra. This was later incorporated into the Commonwealth Scientific and Industrial Research Organization (CSIRO), and at the time of his death he was chief officer of the CSIRO Upper Atmosphere Section.

In 1936 Martyn reconciled a number of apparently conflicting observational results by providing a remarkable model of the upper atmosphere. He showed that, although there is a warmer region above the stratosphere, the temperature must drop again to a very low value (about 160 K) at 82 km and then rise to very high values (about 1,000 K) at heights above 250 km. He also concluded that the gases at such heights were fully mixed by winds and so consisted mainly of nitrogen. These results have since been amply confirmed.

Before the Second World War he also collaborated in a number of ionospheric problems including the basis of the theory of interaction of radio waves and the polarization of downcoming radio waves. After the war he continued these studies, discovering the existence of large semidiurnal lunar oscillations in the height and electron density of the ionospheric F region. He showed that the oscillations are the result, not of local winds, but of electrodynamic drifts caused by electric fields generated in the lower "dynamo" or E region and communicated upwards along the highly conducting geomagnetic field lines. Martyn was the first to give a clear outline of the morphology of ionospheric "storms" and to show that they develop almost simultaneously all over the globe according to a relatively simple pattern when expressed in geomagnetic time.

In 1948 Martyn attacked the long outstanding problem of the dynamo theory of the daily geomagnetic variations. The known tidal velocities and electrical conductivity in the ionosphere are inadequate to explain these variations. Martyn suggested that Hall conductivity might remove the discrepancy and later, in collaboration, developed a full theory. He contributed also to the theory of radio emission from the Sun.

Immediately before the Second World War, Martyn was sent to Britain by the Commonwealth Government to learn the secrets of radar. On his return he became the first chief of the Radiophysics Laboratory of CSIRO, where he started radar development in Australia. As director of operational research for the Australian fighting services from 1942 to 1944 he took an important part in the war in the Pacific.

Martyn's greatest contribution to science in Australia was probably his role in the foundation of the Australian Academy of Science. As one of the Fellows of the Royal Society resident in Australia who initiated and carried through this difficult task, he worked indefatigably, with great patience and tact, never allowing the many personal and practical difficulties to dampen his enthusiasm. It was Martyn who as first Secretary (Physical Sciences) produced from the proposals made by his colleagues the statutes and rules, on the basis of which a Royal Charter was presented to the founding fellows by the Queen, during her visit to Canberra in 1954. He was president when he died.

Martyn was chairman of the Australian National Committee for Space Research and the United Nations Scientific and Technical Committee on the Peaceful Uses of Outer Space. He served with URSI as chairman of the Radio Astronomy Commission and as chairman of the Ionosphere Commission. He was awarded the Chree Medal of the Physical Society of London in 1954, the Lyle Medal of the Australian National Research Council in 1947, the Sidey Medal of the Royal Society of New Zealand in 1947 and the Burfitt Medal of the Royal Society of NSW in 1950, and his contributions to science were recognized by other learned societies. He was elected to the Royal Society in 1950.

David Martyn was a man of strong convictions, held tenaciously and often pugnaciously, so that his friendships and his enmities brought him troubles and anxieties. He fought fearlessly for integrity and high standards in science. He is survived by his widow whom he married in 1944.

Correspondence

Dust-up in Nevada

SIR,—*Nature* states[1] that Emiliani *et al.*[2] did not prove a causal relationship between underground nuclear explosions and earthquakes. If a proof was not provided, it is not for the reasons advanced by *Nature* but for the much more fundamental reason that you cannot prove anything by statistics.

In the paper in question[2], it was stated that significant earthquake activity increase took place in annuli up to 860 km away from testpoint. Anderson *et al.*[3] wrote that these results "would be important" if a significant earthquake activity increase could be shown between 400 and 860 km from testpoint. In their reply, Emiliani *et al.*[4] showed just that. Therefore, the results obtained should be important, at least by CalTech standards. However, it is within the realm of statistical possibility that analysis of data across a much greater time interval (largely as yet not available) might lead to different or even opposite conclusions.

Nature is correct in claiming that the reaction of nine distinguished seismologists to our paper is more psychological than geophysical. The overreaction is explained by the fact that the authors of the paper are not seismologists and have never contributed to this field, thus making their contribution of (presumably) important results vastly annoying to some. As to priorities, the first published suggestion to use underground nuclear explosions to control earthquakes is due to Brune and Pomeroy[6]. This idea, however, appears to have been previously the object of informal discussion and speculation[5] to which, alas, Emiliani *et al.* were not invited (personal communication).

Yours faithfully,

C. EMILIANI

Coping with Oil Slicks

SIR,—In his letter about oil slicks (*Nature*, **226**, 573; 1970) Mr B. Pounder advocated taking away from the Board of Trade responsibility for dealing with oil pollution at sea because of the Board's alleged impotence in the face of the technical problems involved.

This responsibility was given to the Board of Trade last summer because it was the civil department in the best position to undertake it. The major work of planning that was required all round the coast is now well advanced and the Board is procuring special equipment to enable it to deal with serious spillages. The Board does not stand alone in this work, but can call upon the help of the Royal Navy and the Royal Air Force and on scientific and technical advice from Government laboratories, especially the Warren Spring Laboratory.

However, this does not mean that we shall be able to clear up every oil slick at sea. The obstacle to this is not technical but economic. The slicks reported round our coasts are numerous, and to attempt to investigate and deal with each one would be disproportionately costly in money and resources. Our planning must therefore concentrate on serious spillages threatening the coast.

The real answer to the threat to seabirds from continual relatively minor oil pollution is to prevent the oil from getting on to the sea in the first place by bringing in a more readily enforceable set of restrictions on discharges from ships. This has to be an international matter, and the United Kingdom has taken the lead in securing agreement to amendments to the International Convention on Prevention of Pollution of the Sea by Oil 1954 for this very purpose. The Oil in Navigable Waters Bill that was introduced into Parliament on May 12 is intended to enable the government to accept these amendments formally.

Yours faithfully,

MICHAEL YOUNG

London SW1.

Prowess of P's

SIR,—Dr Weale (*Nature*, **226**, 195; 1970) suggests that there may be a marginal disadvantage in having a name beginning with a letter coming towards the end of the alphabet. A few years ago I noticed that the midpoint in the membership lists of the Biochemical and Nutrition Societies came among the Ls whereas in the Royal Society and National Academy of Sciences lists it was in the Ks. This suggested a slight forward drift in organizations recruited on the basis of apparent merit. It would be interesting if someone with more patience would conduct a more comprehensive survey.

Yours faithfully,

N. W. PIRIE

42 Leyton Road,
Harpenden, Hertfordshire.

Tektites tracked to Toba

SIR,—D. H. McColl and G. E. Williams are to be congratulated on their excellent observation[1] concerning the pattern of tektite infall in Australia. Making the assumptions that each line of infalling tektites was ejected from its own aperture of a cryptovolcanic structure, with velocities between 8 and 8·5 km/s, with azimuths of 135° and 150°, and with angles of elevation of approximately 75°, brings the intersection point of the infall lines to Lake Toba, Sumatra, after consideration of the effect of the Earth's rotation.

Lake Toba is considered a volcano-tectonic sink of the Pleistocene age[2], and is as unlikely a cryptovolcanic structure as one could hope to nominate. I should like, however, to suggest that its age be more accurately determined and that the area be investigated for the presence of coesite and shattercones.

Yours faithfully,

C. W. KAYSING

Announcements

University News

Dr Paul A. Marks, acting dean of the College of Physicians and Surgeons, has been appointed dean of the Faculty of Medicine and vice-president for medical affairs at **Columbia University,** in succession to Dr H. Houston Merritt.

Professor E. N. Hiebert, University of Wisconsin, has been appointed professor of the history of science at **Harvard University.**

A Research Unit for Instrument Physics has been established in the Department of Applied Physical Sciences, University of Reading, under the supervision of Professor P. B. Fellgett. **Dr G. F. Reynolds,** director of research and development, Shandon Scientific Company Limited, has been appointed head of the new Unit, which will be concerned primarily with industrial collaboration and with industrial research and consultancy. At first, the Unit will be supported by the University Grants Committee, but it is hoped that the fees for projects undertaken will enable it to become self-supporting. Work is already under way on problems concerning meteorological instruments, machine tools, and plastics optical systems and components, and suggestions for further projects will be welcome. Further details about the Unit can be obtained from Dr G. F. Reynolds, Research Unit for Instrument Physics, Department of Applied Physical Sciences, University of Reading, Whiteknights, Reading RG6 2AY, Berkshire.

Appointments

Dr Anna M. MacLeod, Heriot-Watt University, Edinburgh, has been made the first woman president of the Institute of Brewing.

Professor Albert B. Sabin was formally installed as **President of the Weizmann Institute of Science** on May 4.

Mr A. G. Beynon, director of Veterinary Field Services, has been appointed **Chief Veterinary Officer of the Ministry of Agriculture, Fisheries and Food,** in succession to Mr J. Reid.

Mr Frank O'Hara, Royal Aircraft Establishment, Bedford, has been appointed **Director-General of Civil Aircraft and General Services Research Development in the Ministry of Technology,** in succession to Mr D. E. Morris.

Miscellaneous

The **Experimental Pathology Club prize** for 1970 has been awarded to **Mr R. A. Little,** MRC Toxicology Unit, for his essay "The Effect of Age on the Response to Injury".

The **Spearman medal** of the British Psychological Society has been awarded to **Dr K. J. Connolly,** University of Sheffield, for his research on the genetics of behaviour and the development of skill in children.

The Council of the Royal Society has awarded a **Bruno Mendel travelling fellowship** to **Miss R. Ashkenazi,** Hebrew University—Hadassah Medical School, to enable her to work for one year at the ARC Institute of Animal Physiology, Babraham.

Dr A. R. C. Westwood, deputy director of the Research Institute for Advanced Studies, Martin Marietta Corporation, has been awarded a gold medal and a prize of £100 by the administrators of the Sir George Beilby Memorial Fund, for his work in materials science.

ERRATUM. The following corrections should be made in the article "Increase in Antiviral Activity of Polynucleotides by Thermal Activation" by E. de Clercq, R. D. Wells and T. C. Merigan (*Nature*, **226**, 364; 1970): The second sentence of the first paragraph should read "The thermal activating effect . . . was most marked with the alternating polyribonucleotides such as poly (A–U) and poly (I–C)". The second footnote in Table 1 should read "†Minimal Eagle's medium (MEM), *p*H 7·0–7·5 . . . ". In the paragraph following Table 1, the first sentence should read "Preincubation at 37° C, compared with 0° C, rendered all polynucleotides, including poly I·poly C, significantly more active in reducing virus plaque formation in human cells, when the incubation was carried out in MEM (Table 1)", and the sentence beginning on line 16 of that paragraph should read "Addition of 10^{-3} M EDTA following the 37° C incubation step or rapid cooling to 0° C (by immersion in solid CO_2–ethanol) did not reverse the activating effect . . . ".

International Meetings

June 3–4, **Launching the Corporate Plan,** Brussels (Administrative Secretary, European Society of Corporate and Strategic Planners, 71 rue de la Loi, B-1040 Brussels, Belgium).

June 7–9, **Computer Applications in the Earth Sciences,** Lawrence (R. F. Treece, University Extension, University of Kansas, Lawrence, Kansas 66044, USA).

June 9–11, **Electrical Interference in Instrumentation,** London (The Manager, Conference Department, IEE, Savoy Place, London WC2R OBL).

June 10, **Biochemistry of Photosynthesis,** London (Dr D. O. Hall, King's College, 68 Half Moon Lane, London SE24).

June 16–19, **Hospital Equipment Medical Engineering and Services Exhibition,** London (Posner-Cox Public Relations, 102 Charing Cross Road, London WC2).

June 18, **Animal Viruses as Genetic Modifiers of the Cell,** London (The Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1).

June 29–July 2, **Book Indexing** (training course), London (Mr L. M. Harrod, c/o School of Librarianship, North Western Polytechnic, 207–225 Essex Road, London N1).

July 5–6, **Liquid Scintillation Counting for Radioisotope Measurement,** San Francisco (C. T. Peng, School of Pharmacy, University of California, San Francisco, California 94122, USA).

July 6–10, **Microwave Spectroscopy,** Bangor (Professor J. Sheridan, Department of Chemistry, University College of North Wales, Bangor, Caernarvonshire).

July 7–9, **Scanning Electron Microscopy in Materials Science,** Newcastle upon Tyne (E. H. Boult, School of Chemistry, The University, Newcastle upon Tyne NE1 7RU).

July 25–30, **Applied Psychology,** Liège (EDITEST, rue Général Capiaumont, 94–1040 Bruxelles, Belgium).

August 5–7, **Applications of X-ray Analysis,** Denver (Metallurgy and Materials Science Department, Denver

Research Institute, University of Denver, Denver, Colorado 80210, USA).

August 18–27, **General Assembly of the International Astronomical Union,** Brighton (Press Office, Science Research Council, State House, High Holborn, London WC1R 4TA).

September 7–9, **Ion Implantation,** Reading (Meetings Officer, The Institute of Physics and the Physical Society, 47 Belgrave Square, London SW1).

September 13–15, **Science and Technology of Metal Materials,** Tremezzo (Fondazione "Guido Donegani", Accademia Nazionale dei Lincei, Via della Lungara 10, 00165 Roma, Italy).

September 15–18, **Gas Discharges,** London (Manager, Conference Department, IEE, Savoy Place, London WC2R OBL).

September 27–October 2, **Cell Walls and Cell Membranes,** Ashford, Kent (Executive Secretary, 7 Warwick Court, London WC1R 5DP).

September 29–October 1, **Autumn Meeting of the Chemical Society,** London (Dr John F. Gibson, The Chemical Society, Burlington House, London W1V OBN).

October 28–29, **Radiation and Isotope Techniques in the Building Industry,** Brussels (EURISOTOP Office, Commission of the European Communities, Berlaymont Building, 200 rue de la Loi, B-1040 Brussels, Belgium).

November 10–12, **Laboratory Automation,** London (Conference Registrar, Institution of Electronic and Radio Engineers, 8–9 Bedford Square, London WC1B 3RG).

Sabbatical Itinerants

In the hope of providing some practical assistance in the good cause of mobility between laboratories, *Nature* advertises the needs for housing of families about to take up periods of sabbatical leave. To begin with, no charge will be made for advertisements like this. It is hoped that a period of experiment will show what form these advertisements could most usefully take and whether they are effective.

Wanted: Flat in London for 6 months from July 1, 1970, by visiting Australian chemist and wife. Convenient for access to Imperial College. Central heating preferred. Please contact Dr M. J. Gallagher, East Chemistry Building, University of Illinois, Urbana, Illinois 61801, USA.

Wanted: By Dutch lecturer with four children, furnished house, near either the Torry Research Station, Aberdeen, or Unilever Research Laboratories, Bedford. From July to October inclusive. State whether crockery and blankets can be provided. Please contact Professor D. G. Hawkridge, Open University, Bletchley, Buckinghamshire, before June 21.

Wanted: Furnished 3 bedroom house or flat in London or environs, with easy access to Chelsea College, from September 1, 1970, for approximately one year. Please contact Professor John W. Martin, Department of Chemistry, Bridgewater College, Bridgewater, Virginia 22812, USA.

Vacant: Modern detached house in Hassocks to let from mid-July for one year. Three bedrooms, lounge, dining room, central heating. Close to Brighton and the University of Sussex. London one hour by rail. Please contact Dr A. D. Baddeley, 47 Wilmington Close, Hassocks, Sussex.

British Diary

Tuesday, May 26

Excavations at Marlik (5.45 p.m.) Professor E. O. Negahban (Tehran) University of London, at the Institute of Archaeology, 31–34 Gordon Square, London WC1.

Vibration Theory I (6 p.m.) Professor B. Fraeijs de Veubeke, University of London, at Queen Mary College, London E1.

Wednesday, May 27

Eighth Annual Tribology Group Convention (three days) Institution of Mechanical Engineers, Tribology Group, at Brighton.

Electronic Circuits for Medical Instrumentation (2 p.m. discussion meeting) Institution of Electronic and Radio Engineers, Joint IEE/IERE Medical and Biological Electronics Group, at the Institution of Electrical Engineers, Savoy Place, London WC2.

Human Pituitary Diseases (5.30 p.m.) Professor Russell Fraser, University of London, at the Royal College of Physicians, St. Andrew's Place, London NW1. (Sandoz Foundation Lecture in Endocrinology.)

The Architect and Power Engineering (5.30 p.m.) The Rt. Hon. The Lord Holford of Kemp Town, Institution of Electrical Engineers, at Savoy Place, London WC2.

Thursday, May 28

Annual General Meeting followed by Technical Films (5.30 p.m.) Institution of Electrical Engineers, at Savoy Place, London WC2.

Challenge of the Environment to Architecture and Building Science (5.30 p.m.) Professor Albert G. H. Dietz (Massachusetts), University of London, in the Botany Theatre, University College London, Gower Street, London WC1.

Computer Aids in Mechanical Engineering Design and Manufacture (9.30 a.m. discussion meeting) Royal Society, at 6 Carlton House Terrace, London SW1.

On Line Electrochemical Sensors (6.30 p.m.) Society for Analytical Chemistry, Electroanalytical and the Automatic Methods Groups, at the Leicester Lounge, 44 Glasshouse Street, London W1.

Regional Variation in Indian Ocean Coral Reefs (two-day symposium) Royal Society and the Zoological Society of London, in the Meeting Room of the Zoological Society of London, Regent's Park, London NW1.

Virtues and Vices of Pressure Testing (6 p.m. discussion meeting) Institution of Mechanical Engineers, Applied Mechanics Group, at 1 Birdcage Walk, London SW1.

Friday, May 29

Developmental and Diagnostic Pathology of Endocrine Polypeptide Tumours (11 a.m.) Professor A. G. E. Pearse, University of London, at the Royal Postgraduate Medical School, Du Cane Road, London W12.

Monday, June 1

Immunological Tolerance: Its Possible Role in Organ Transplantation (5 p.m.) Professor L. Brent, University of London, at the Wright-Fleming Institute, St. Mary's Hospital Medical School, Norfolk Place, London W2.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire	**£14.0.0** each
United States of America........(by air freight)	**\$48** each
Canada........(by air freight)	**\$52** each
Elsewhere overseas by surface mail	**£14.0.0** each

(Charge for delivery by air mail on application)

*Shorter periods *pro rata*. (Minimum three months.)

UNIVERSITY OF LONDON KING'S COLLEGE

DEPARTMENT OF CHEMISTRY

Applications are invited for two POSTGRADUATE awards (S.R.C. rates plus fees) for research in the field of organophosphorus chemistry. Candidates would be expected to register for the degree of Ph.D. (University of London) and should have, or expect to have, a good B.Sc. degree or equivalent qualifications. The Department is fully equipped with modern instruments (including n.m.r. and e.s.r.) and attendance at postgraduate summer courses would be supported and encouraged.

Applications (including curriculum vitae and the names of two referees), should be sent, as soon as possible, to Dr. C. D. Hall (c/o Professor D. H. Hey, F.R.S.), Department of Chemistry, King's College London, Strand, London, WC2R 2LS.

(1934)

UNIVERSITY OF SOUTHAMPTON

INSTITUTE OF SOUND AND VIBRATION RESEARCH

LECTURESHIP IN STRUCTURAL DYNAMICS

Applications are invited for the post of Lecturer in the Institute of Sound and Vibration Research. Applicants should have experience and research interests in the field of structural dynamics. The person appointed will be expected to assist in the undergraduate and postgraduate teaching in the Institute and also to develop research work in one or more aspects of structural dynamics. Salary scale: £1,585 to £2,850 with a merit bar at £2,045.

Further particulars may be obtained from the Deputy Secretary, The University, Southampton SO9 5NH, to whom applications (seven copies from United Kingdom applicants) should be sent by not later than May 30, 1970, quoting ref.: N. (1922)

UNIVERSITY OF LONDON

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

COURTAULD INSTITUTE OF BIOCHEMISTRY

A graduate Biochemist is needed to undertake a study of the Biosynthesis of Plasma Lipoproteins of the role of the Liver in maintaining plasma lipoprotein patterns. The appointment, initially for three years, will provide opportunities for study for a higher degree. Salary, subject to review, within the scale £860 to £1,010 and superannuation under the F.S.S.U.

Applications to Dr. Mills, Courtauld Institute, The Middlesex Hospital Medical School, London, W1P 5PR. (1965)

UNIVERSITY OF GLASGOW

RESEARCH ASSISTANT IN DENTAL BIOCHEMISTRY

Applications are invited from graduates with an Honours degree in Biochemistry or related subject for the post of Research Assistant in Dental Biochemistry. The successful applicant will perform research into the enzymology of carbohydrate metabolism by bacteria. The project will be partially financed by an award from the Medical Research Council and may provide the opportunity for a suitably qualified candidate to register for a higher degree. Salary scale—if postdoctoral £1,240 to £1,470 per annum, otherwise £800 to £1,250 per annum. F.S.S.U.

Applications (three copies), should be lodged with the undersigned, from whom further particulars may be obtained. In reply please quote Ref. No. 5016-M.

ROBT. T. HUTCHESON,
Secretary of the University Court.

(1931)

For further Classified advertisements see page iv

AUSTRALIA

NEW SOUTH WALES DEPARTMENT OF AGRICULTURE

Senior Research Officer

(WHEAT BREEDING AND GENETICS)

Agricultural Research Institute, Wagga Wagga

Applications are invited for the above position.

Salary

$A6,551 Range $A7,004 per annum with progression to $A7,571 per annum subject to conditions.

Qualifications

Degree in Agricultural Science or equivalent

Experience

essential—several years experience in Wheat Breeding and/or Wheat Genetics.

Duties

To formulate and pursue a research programme in Wheat improvement in both basic and applied aspects, and to continue an existing programme in these areas.

Accommodation

Single accommodation can be supplied to male appointees at $A7–41 per week.

Appointment and Travel

the services of the appointee are required as soon as possible and applicants should be prepared to emigrate in the near future

Subject to certain conditions the successful applicant will be eligible for:

- ★ Payment of fares to Sydney.
- ★ Financial assistance towards removal and establishment expenses.
- ★ Financial assistance towards initial accommodation expenses.

For further information and application form write to the Recruitment Section, New South Wales, Government Offices, 56 Strand, London, W.C.2, where applications close on the **19th JUNE 1970**. When writing please quote reference 44/442

Hon. A. Landa, Agent General.

KODANSHA (PUBLISHERS) LTD., TOKYO

ENGLISH LANGUAGE EDITOR (CHEMISTRY)

Kodansha, Japan's principal publisher, has an immediate opening for a full-time English Language Editor to prepare manuscripts for publication in the field of chemistry.

Requirements:	Hons. degree in chemistry minimum; preferably postgraduate studies in polymer science or related subjects; experience in book publishing. English as mother tongue; knowledge of Japanese useful but not essential.
Duties:	Language correction of translations from Japanese; editing and preparing manuscripts for book publication. Full responsibility.
Conditions:	Initial term 2 years, renewable by agreement. Good salary, commensurate with experience and qualifications. Passages paid.

Written applications stating full name, place, date and year of birth, nationality, marital status, present employment, details of education, qualifications and experience, and previous acquaintance with Japan, if any, should be addressed to **Mr. Y. Haga, Dept. of Research for Scientific Edition, Kodansha Ltd., 12-21, Otowa 2-chome, Bunkyo-ku, Tokyo 112, Japan,** to arrive not later than 17 June, 1970.

(2027)

National Council for Scientific Research, Lusaka - Zambia

VACANCIES EXIST FOR PROFESSIONAL AND TECHNICAL OFFICERS AS UNDER:

PROFESSIONAL OFFICERS

1. Entomologist—Tsetse Breeding—Tsetse Research Team

Duties: To maintain and develop colonies of tsetse fly, and to carry out research investigations leading to improved fly breeding and feeding techniques. To cooperate with other members of the team in the various projects leading to the use of chemosterilization for tsetse eradication.

Qualifications: Good University Hons. Graduate in Entomology or alternatively Zoology or Biology with appropriate graduate and post graduate training or experience. Approved post graduate experience in entomology would be required, and it would be particularly advantageous if this were in the field of tsetse.

2. Ecologist—Tsetse Research Team

Duties: To investigate the relationship of tsetse populations to various components of their habitat, in connection with research into the use of chemosterilants as a means of tsetse eradication.

Qualifications: Good University Hons. Graduate in Zoology, Ecology, Entomology or other appropriate subjects. Post graduate research and/or practical experience in ecology, field entomology or related areas would be required. A knowledge of tsetse control activities would be advantageous, as would experience in the direction of field workers.

3. Field Ecologist—Unit of Tick Bionomics

Duties: To assist in field work on tick biology, host relationships and disease transmission.

Qualifications: Degree in biology, agriculture or veterinary science.

4. Microbiologist—Unit of Tick Bionomics

Duties: Biology of microbes associated with ticks, including mammal pathogenicity.

Qualifications: Biologist, Hons. degree or equivalent in Zoology. Post graduate experience of modern methods of cultivation and typing of micro-organisms. Familiarity with veterinary pathogens an advantage, but not essential.

5. Insect Physiologist—Unit of Tick Bionomics

Duties: The influence of environment on survival development and reproduction of ticks, the behaviour responses of ticks, and the biochemistry of host stimuli.

Qualifications: Hons. degree or equivalent in Biology, with post graduate experience in insect physiology. Experience of modern biochemical techniques an advantage.

TECHNICAL OFFICERS

1. Tsetse Research

Duties: To be responsible, under the direction of the Professional Officers, for the execution of the research programme. In particular the day-to-day running of the field investigations, together with the collecting and maintenance of all necessary records on tsetse populations, etc., would be a major responsibility.

Qualifications: G.C.E. 'O' levels or equivalent, together with a suitable diploma or alternatively experience and inservice training. The applicant should have experience in tsetse field investigations or closely related field projects, He should also have experience of man management, and will probably have worked in a tsetse control department. game department or similar organization.

2. Unit of Tick Bionomics

(a) One technical Officer with experience of pathological and diagnostic methods.
(b) One technical officer with entomological training. To be in charge of laboratory work on ticks.
(c) One technical officer with entomological or general parasitological training, or training in or experience of animal husbandry.

Qualifications: G.C.E. 'O' levels or equivalent, together with a suitable diploma or alternatively appropriate experience and inservice training. He should also have experience of man management.

According to qualifications and experience, salary scales are as follows:

Professional Officers	K2,610 × 240—K3,810	(Graduates with at least 3 years' post graduate experience)
Senior Professional Officers	K4,050 × 240—K5,010	(Ph.D. qualifications and six years' experience)
Principal Professional Officers	K5,250 × 180—K5,970	(Ph.D. qualification and ten years' experience)
Technical Officers, Grade III	K1,440 × 120—K1,800	(Diploma or equivalent)
Technical Officers, Grade II	K1,800 × 180—K2,180	(University degree or equivalent)
Technical Officers, Grade I	K2,280 × 180—K3,720	(University degree and experience)

For Zambians there is a superannuation scheme. Non-Zambians will be paid a gratuity of 25 per cent of aggregate basic salary earned during resident service of not less than thirty months. Non-Zambians will be paid a contract allowance of K600 per annum. Accommodation will be provided at an economic rental of 10 per cent of basic salary. Hard furniture will be provided.

Applications (five copies) giving full personal details, qualifications and experience, and naming three referees, to be sent to the Secretary-General, National Council for Scientific Research, P.O. Box RW 166, Ridgeway, Lusaka, Zambia, from whom further particulars may be obtained.

Closing date June 30, 1970.

(K1—US$1.4 K1—£ sterling .58)

(2098)

UNIVERSITY OF DUBLIN
Trinity College

LECTURESHIP IN BIOCHEMISTRY

Applications are invited for the above post which has been established in conjunction with the Irish Flour Millers' Association.

The lecturer, who should have experience in the chemistry or biochemistry of proteins, will be expected to interest himself in research on the chemical and nutritional aspects of flour.

Salary Scale:
£1,650 × 67 – £1,985 (Merit Bar)
£2,088 × 67 – £2,892

It is not expected that an appointment will be made above the Bar in the Lecturer's scale.

Marriage and children's allowances are paid and there is a non-contributory F.S.S.U.-type pension scheme.

Further particulars may be obtained from:

The Assistant Secretary (Staff),
Trinity College,
Dublin 2.

who will receive completed applications up to June 22, 1970. (2109)

AUSTRALIA

Queensland Institute of Technology

BRISBANE

Applications are invited for the following positions :

Department of Biological Science

SENIOR LECTURERS
LECTURER

Positions are available in the following fields :

Genetics—population genetics, human genetics, or microbial genetics.
Education in Biological Sciences.
Fresh-water Ecology.
Herbicides. Entomology.

Initiative in the development of applied research programmes ancillary to the courses offered is a primary concern of the Department. The Department conducts a degree level course in Biological Science.

Department of Chemistry

LECTURERS IN GEOLOGY

Positions are available in the following fields :

Sedimentology.
Stratigraphy. Palaeontology.

Suitably qualified persons with experience in other aspects of geology should apply. A three-year Associate Diploma in Applied Geology may be introduced in 1971. This will be of degree standard.

Department of Physics

SENIOR LECTURER
LECTURERS

The Senior Lecturer should have a major interest and experience in one of the fields of applied physics with a definite bias towards experimental applied physics in the areas of :

Applied Geophysics.
Materials Science. Biophysics.

The Lecturer should have interest and experience in one of the fields of applied physics.

Qualifications

Applicants should possess at least an honours degree or equivalent and should have adequate experience.

Salary Ranges

Senior Lecturer A, $A7,500 to $A8,750.
Lecturer Grade IA, $A5,400 to $A7,300.
Lecturer Grade II, $A4,400 to $A6,000.

Salaries of the A scale are equivalent to University rates and will be subject to future movements of University salaries.

Appointments will be made within the above ranges according to qualifications and experience.

Application forms and further details available from Queensland Government Offices, 392/393 Strand, London, W.C.2.

Closing date—June 15, 1970. (2086)

BIOCHEMIST

The Centre needs a biochemist to develop methods of labelling with carbon-14 and tritium using enzymatic or microbiological synthesis. The work requires a continuing awareness of the needs of users of these products in university and medical research units in this country and abroad.

Applicants should possess a good honours degree and have at least two years' post-graduate experience in research and development. The starting salary, determined by the successful candidate's age and experience, will be within the range £1,630–£2,895.

Housing or assistance towards house purchase may be available.

Application forms may be had from the Personnel Officer (Ref: S.162)

THE QUEEN'S AWARD TO INDUSTRY 1967 1970

The Radiochemical Centre
Amersham Bucks

(2045)

Elsevier Publishing Company

(International Publishers of scientific journals and books) has immediate openings for full-time

Editorial Assistants

Requirements:
- Degree or equivalent education in geology, chemistry, biochemistry or biomedicine
- English as mother tongue
- High degree of accuracy

Responsibilities:
- Language correction of contributions written by non-English-speaking authors
- Subediting and proof-reading

We offer:
- Responsible work in a congenial atmosphere
- Salary according to qualifications
- Good social security arrangements

Handwritten applications, giving details of education and previous experience and an indication of the salary expected, should be addressed to the **Personnel Department of Elsevier Publishing Company, P.O. Box 211, Amsterdam, The Netherlands.**

(2105)

GEOLOGISTS

COMMONWEALTH OF AUSTRALIA

Bureau of Mineral Resources

These are senior positions offering first class career opportunities. The appointments are based in Canberra, but periods of field duty will be called for from time to time.

Position 1—($A6,868–$A7,573)—to check samples supplied from drilling operations and arrange for palaeontological and petrological examination of cores and cuttings. Examine all cores and report on lithology and sedimentary structures in a form suitable for publication. Prepare critical comments, for publication, on final reports. Visit drilling operations to check on methods and equipment used by well-site geologists.

Position 2—($A5,905–$A6,631)—To undertake complex studies (in both field and laboratory) of sediments for determination of their sources, environment of deposition and post-depositional history. Prepare scientific reports, plans, sections and diagrams dealing with these investigations. Supervise subordinate staff as required.

Qualifications—Appropriate science degree at good honours level or higher degree together with considerable related experience. For position 2, experience in carbonate sedimentology will be preferred.

Salaries—Commencing salary for both positions will depend on qualifications and experience ($A1 = 9/4d. sterling).

Allowances—Travelling, camping, district and overtime allowances are payable where applicable.

Conditions—First class passages, by sea or air for successful applicants and their dependants, together with generous baggage allowances. Salary paid from date of embarkation. Three weeks' annual leave and cumulative sick leave provisions. For British subjects there is a comprehensive Superannuation Scheme.

Application forms may be obained from:

The Recruitment Officer,
Office of the Public Service Board,
Canberra House, 10–16 Maltravers Street,
Strand, London, W.C.2

Please state in which position you are interested.

(2064)

University of Leiden, The Netherlands

Faculty of Medicine

CHAIR OF PHYSIOLOGY

Applications are invited for an appointment to the above-mentioned chair, rendered vacant by the death of Professor J. W. Duyff, M.D.

The appointment will carry with it the responsibility for co-ordinating physiological research projects within the Department of Physiology as well as in clinical departments of the University Medical Centre, and preference will be given to applicants with research interests related to clinical physiology.

Further particulars may be obtained from, and applications should be submitted to, the Advisory Committee,

c/o Professor E. L. Noach,
Department of Pharmacology,
Wassenaarseweg 62,
Leiden.

(2103)

UNIVERSITY OF GLASGOW

LECTURESHIP IN PHYSIOLOGY

Applications are invited for a LECTURESHIP IN PHYSIOLOGY. Salary within the range £1,240 to £2,850 per annum on the Lecturers' scale (presently under review). Initial salary will be fixed according to experience and qualifications. F.S.S.U.

Applications (eight copies) should be lodged not later than June 4, 1970, with the undersigned, from whom further particulars may be obtained. In reply please quote Ref. No. 3026-M.

ROBT. T. HUTCHESON,
Secretary of the University Court.

(1992)

MACQUARIE UNIVERSITY SYDNEY, AUSTRALIA

Applications are invited for appointment to positions in the fields indicated below. The positions are tenable from the commencement of 1971. Normally appointees should take up duty by mid-February, 1971. Later dates of entry on duty may be arranged in special cases.

SENIOR LECTURERS/ LECTURERS

BIOLOGY

School of Biological Sciences (lecturers only, in the fields of animal physiology, ecology and animal population or biochemical genetics).

CHEMISTRY

School of Chemistry (lecturer only, any field).

The salary for a Senior Lecturer will be within the range $A7,600 by $A230 to $A8,750 per annum; and for a Lecturer $A5,400 (6) by $A270, (1) by $A280 to $A7,300 per annum. These salaries are at present under review.

Macquarie University occupies an attractive site in Sydney, and is planned to develop rapidly over the next decade. The University commenced postgraduate teaching in 1966 and undergraduate teaching in 1967. Some 4,200 students are currently enrolled including approximately 400 postgraduate students. The organisation of the University provides considerable flexibility in the construction of degree courses for individual students and provides for interdisciplinary studies.

Further information, including advice regarding the method of application, should be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, Macquarie University, North Ryde, New South Wales 2113, Australia.

Applications close on June 26, 1970.

(2068)

UNIVERSITY OF SOUTHAMPTON

INSTITUTE OF SOUND AND VIBRATION RESEARCH

Applications are invited for the post of Shell-Mex and B.P. Lecturer. There will be lecturing commitments in human factors at both undergraduate and postgraduate level. In addition to primary interests in sound and vibration, the successful candidate will be expected to conduct and organize research in a wider variety of human factors, with particular reference to the transportation environment. Salary scale £1,730 to £3,105, with a merit bar at £2,230. F.S.S.U.

Further particulars may be obtained from the Deputy Secretary, The University, Southampton, SO9 5NH, to whom applications should be sent before May 30, 1970, quoting ref.: N

Chemical Applications of Far Infrared Spectroscopy

A. Finch, P. N. Gates, K. Radcliffe *Royal Holloway College, Surrey, England*
F. N. Dickson *Mellon Institute, Pittsburgh, Pennsylvania, USA*
and F. F. Bentley *Materials Division, Wright-Patterson Air Force Base, Dayton, Ohio, USA*
May 1970, viii+278 pp., 100s. (£5.00)

This book is an account of the applications, techniques and instrumentation of far-infrared spectroscopy, and interferometry: a definitive work intended for students, researchers and industrial workers concerned with the application of vibrational spectroscopy to problems of chemical interest.

Contents Introduction. Instrumental considerations in the design of far-infrared spectrometers. Techniques. Barriers to internal rotation: Torsions. Hydrogen-bonded and charge-transfer systems. Complex inorganic systems. Metal-organic and organic compounds. Spectroscopy of crystal lattices. Author index. Subject index.

Space through the Ages

The evolution of geometrical ideas from Pythagoras to Hilbert and Einstein
C. Lanczos *Dublin Institute for Advanced Studies, School of Theoretical Physics, Dublin, Ireland*
May 1970, x+320 pp., 80s. (£4.00)

This book presents the philosophical logic of deduction and induction in the development of the aesthetic concepts of man's perception of space. As a history of geometrical thinking, this work will interest all mathematicians, logicians, philosophers, and physicists, as well as students who have an understanding of the basic concepts of algebra and calculus.

Contents Early beginnings. Greek geometry. The evolution of metrical geometry. Tensor algebra. Tensor analysis. The geometry of Gauss and Riemann. Einstein's theory of gravitation. Abstract spaces. Projective geometry. Bibliographical index. General index.

Advances in Microbial Physiology Volume 4

Edited by A. H. Rose *School of Biological Sciences, University of Bath, England*
and J. F. Wilkinson *Department of General Microbiology, University of Edinburgh, Scotland*
April 1970, xii+354 pp., 105s. (£5.25)

This series presents critical review articles on all aspects of the physiological and biochemical activities of micro-organisms. It deals with subjects of interest to microbiologists and biochemists which have until now received little attention from reviewers.

Contents Biosynthesis of secondary metabolites: roles of trace metals. Antimicrobial agents and membrane function. Encystment in amoebae. Serotype expression in paramecium. The aliphatic amidases of *Pseudonomas aeruginosa*. The place of continuous culture in microbiological research. Catabolite repression and other control mechanisms in carbohydrate utilization. Author index. Subject index.

Methods in Microbiology Volume 3A

Edited by J. R. Norris *Milstead Laboratory of Chemical Enzymology, Sittingbourne, Kent, England*
and D. W. Ribbons
Department of Biochemistry, University of Miami School of Medicine, and Howard Hughes Medical Institute, Miami, Florida, USA
April 1970, xii+506 pp., 140s. (£7.00)

This volume is concerned with the techniques used for isolating, growing and preserving micro-organisms.

Contents Media for the maintenance and preservation of bacteria. Culture collections and the preservation of bacteria. Design and formulation of microbial culture media. Quantitative relationships between growth media constituents and cellular yields and composition. Enrichment cultures of prokaryotic organisms. The isolation of mutants. Improvement of micro-organisms by mutation, hybridization and selection. Author index. Subject index.

FEBS Proceedings of the Sixth Meeting, Madrid April 1969

Volume 19: Metabolic Regulation and Enzyme Action

Edited by A. Sols *Institute of Enzymology, Madrid, Spain*
and S. Grisolia *University of Kansas Medical Center, Kansas City, Kansas, USA*
May 1970, x+382 pp., 105s. (£5.25)

The volume contains thirty-five papers presented at two symposia, one on "Metabolic Regulation" and another on "Mechanisms of Enzyme Action", and at a colloquium on "Enzyme Pathology", all held at the Madrid FEBS Meeting in April 1969.

It presents a very significant proportion of the current research trends in key areas of these two fields, particularly in such fundamental problems as gene expression, complex metabolic pathways, interconvertible enyzmes, active sites, modulation of enzyme activity, and molecular bases of inborn metabolic errors.

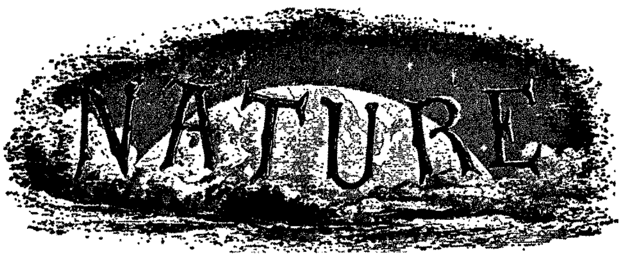
Knowing Where to Draw the Line

THE decision to hive off the special laboratories at MIT is at once sensible and courageous. The Lincoln Laboratory and the Draper Laboratory have been thorns in the institute's flesh for at least two years. More than a year ago, in March 1969, they were the focus of the one-day strike against too close a mixture of military and academic research which spread outwards from MIT to several other universities. Before and since, the special laboratories at MIT have also become familiar parts of the protests of the students against the establishment. But openly to acknowledge that the step now to be taken to separate the two laboratories from the institute is a step in the direction which the students have been urging is not a victory for out and out radicalism—indeed, for the more extreme among the students, the steps now taken may not go far enough (see page 793). The truth is that the anomalies which the Lincoln and Draper Laboratories have created go back much earlier than the past few years of campus discontent. For at least a decade, entirely level headed people have been saying that MIT had become too dependent on the overheads to be earned from military research. The fact that the institute will now have to look elsewhere for $8 million a year, roughly one seventh of its present budget, at a time when all universities are feeling the pinch is a proof at once of the degree to which MIT has come to rely on subsidies of this kind and of the courage—possibly the courage of despair—with which Dr Howard Johnson has faced up to the need for a clear decision.

The origins of the defence laboratories associated with universities are to be found in the years of hectic preparation for military defence during the Second World War. The Lincoln Laboratory is itself the descendant of the old Radiation Laboratory, at which much American work on radar and associated devices was carried out. Then and since, several American universities have found themselves committed to the management of laboratories like these. Thus the University of California has been ostensibly the manager of the weapons laboratories at Los Alamos and Livermore since the end of the Second World War. In another field, possibly a less contentious one, the California Institute of Technology manages the Jet Propulsion Laboratory on behalf of NASA. Then there are laboratories like the research institutes at places such as Stanford (and until recently at Buffalo) where the natural interests of previous faculty members have led to the setting up of specialized laboratories which live from year to year on military contracts. In the past quarter of a century, these laboratories have performed a valuable service for the military and, by extension, for the United States as a whole. In some cases, but not all (Los Alamos is an obvious exception), the intimate connexion between the university and the laboratory has been of benefit to the latter and sometimes even to the former. In other cases, the mutual benefits of these arrangements have been more mundane in character—defence laboratories managed by universities rid the United States Government of direct responsibility for the continuity of a research programme, and also provide a convenient means by which the salary scales of the public service do not have to be strictly applied. For their trouble, the universities are provided with a frequently handsome overhead. In the present climate, it is hard to know which of these arrangements is the more liable to attack. The argument that the universities should never be associated with military work is obviously untenable—if academics paid no attention to military research, they could even be held to be neglectful of making a proper contribution to the unfortunately necessary task of national defence. Moreover, in the past few years, it has become apparent that much of the research that goes on in university departments has some commercial value, which means that the old simple doctrine of complete access to all academic information has had to be shaded to a significant extent. There is, however, a clear difference between the part-time involvement of a part of an academic's energy in some secret project and the employment by universities of large numbers of full timers all busily engaged on secret projects. The former may be acceptable, but the second has several obvious drawbacks, not least of which is that it can seriously debase the currency of academic life. This is one argument against some of the special laboratories where the university connexion has been strong and intimate. At the other end of the scale, as with Los Alamos, for example, the connexion has been so tenuous that the University of California has always been able with justice to assert that the laboratory has had no adverse effect on the quality of academic life, but this, of course, has laid it open to the charge that it has been living not merely off illgotten but off unearned gains. And tactically, of course, the universities which depend on the overhead contribution from research projects which are not directly under university control are likely to come a cropper any day if there should be a sudden cut in the budget of some mission oriented agency. Dr Johnson's administrators at MIT may find in the weeks ahead some wry comfort in the thought that if they had not voluntarily forgone their commission for operating the special laboratories, the money may have been snatched from them next year by some act of Congress or of the Administration.

Several questions now arise, not the least of which is the likelihood that other universities will find themselves following MIT (California Institute of Technology may yet be lucky that its student body remains one of the most docile, although there is also no doubt that the Jet Propulsion Laboratory is a somewhat different kettle of fish from the Draper Laboratory at MIT). The issue is already alive in the University of California and the chances are that the continued management of Los Alamos and Livermore will be impossible. It is therefore only fair to acknowledge first of all that useful laboratories should have room to carry on if their cosy but anachronistic relationships with universities are severed. It is also important, but in the present climate less likely to be acknowledged, that universities should be helped with money to carry out the research likely to be denied to them now that the overhead contributions with which they have financed a good deal of their internal research are likely to be snatched away.

100 Years Ago



PERHAPS the most extraordinary instance of excessive and depraved appetite on record is that of a French soldier, named Tarare, whose case is described in vol. XXI. of the *Dictionnaire des Sciences Médicales*, by Dr. Percy. He was born near Lyons, and came up to Paris, where his first exploit was to eat a basket of apples—at a friend's expense. On various occasions he swallowed a series of corks and other indigestible materials, which produced such violent colic that he was obliged to attend the Hotel Dieu, and whilst being examined almost managed to swallow the watch-chain and seals of the surgeon in attendance, M. Giraud. Desault, on the occasion of one of these attacks of colic, tried to frighten him out of his gross habits by declaring that it would be necessary to open his stomach, and arranged the instruments; he ran away, and relieved himself by copious draughts of warm water. Soon after he found that his appetite had really increased to an excessive amount, probably owing to the continued irritation produced by these absurd tricks.

In the presence of some officers he swallowed, at one sitting, 30lb. of liver and lights. His insatiable appetite was for once in his life made useful, by his being selected to convey a correspondence between General Beauharnais and a French colonel, which was inserted in a box and swallowed; but he was caught and soundly thrashed. He fell under suspicion of having eaten a child fourteen months old. It is stated that he was of mild and gentle manners and aspect. After death his stomach was found in a very diseased condition.

OLD WORLD

INCOMES

Threat to FSSU Pensions

AN unpleasant and entirely unnecessary surprise is to face 35,000 university teachers in the Finance Bill, which is scheduled to be debated in the House of Commons this week. As members of the pension scheme operated by the Federated Superannuation System for Universities (FSSU), they have enjoyed particular flexibility in the way they receive their retirement benefits, as well as particularly generous provision for dependants in the event of death during service. Unless the relevant clauses are excised from the Finance Bill this week, the value of the FSSU scheme may be severely eroded.

What seems to have happened is that people with larger incomes than FSSU members have exploited the rules of this type of pension scheme as a means of evading tax. The Department of Inland Revenue has worded the new Finance Bill so as to close this loophole, but whether through incompetence, oversight or plain indifference has apparently ignored the fact that FSSU members will be caught in the net as well as the tax evaders.

The basis of the FSSU scheme is that a member contributes 5 per cent of his salary each year towards the scheme and his employer contributes a sum equal to 10 per cent of salary. The pension, which in fact is more like a life assurance, can be received in the form of a lump sum on retirement.

At present the employer's contribution is not considered part of the member's taxable income and in at least two previous finance bills special exceptions have been made to ensure that FSSU contributions remain untaxed. The new Finance Bill makes no exception for the FSSU. Moreover, it is clear that the FSSU will not be counted by the Inland Revenue among the approved list of pension schemes that are exempt from tax.

This means either that the UGC, as paymaster for the universities, will have to make up the added burden of taxation on university teachers' salaries, which it is not prepared to do, or that the FSSU must conform to the new regulations for approved schemes. These, in effect, would destroy the flexibility of the FSSU by restricting the pension payable in a lump sum to a small fraction of the total amount due, the rest being received in weekly payments.

FSSU members and those who represent them may be placing too much hope in a clause of the Finance Bill which gives the Inland Revenue discretion to waive the tax on employers' contributions. Despite the discussions held with the Association of University Teachers (AUT) and the council of the FSSU, the department has apparently given no sign of being prepared to let the FSSU slip through its indiscriminate net.

Perhaps the worst aspect of the Finance Bill in its present form is that if it becomes law it will be retrospective in its application; present members of the FSSU will be denied the kind of benefits to which they had always believed their contributions would entitle them.

TRANSPORT

All Stations to Heathrow

THE best way of carrying passengers from Heathrow airport to the centre of London would be to extend the Piccadilly underground line from Hounslow West to the airport, according to a study group set up by the Ministry of Transport. The extension, which London Transport would be able to build by the mid 1970s, would be 3·5 miles long and might carry 17 million passengers a year by 1981. Alternative schemes for a British Rail link with Heathrow should be ruled out because they would cost up to twice as much as the estimated £19 million for the underground link, the study group concludes in its report (*Rail Links with Heathrow Airport*, Part I; HMSO, London, 12½p).

If, as London Transport claims, the Piccadilly line will be capable of absorbing the extra traffic, this choice will have several further advantages. Passengers would be dispersed easily into the underground network at interchange stations, whereas the proposals by British Rail for a ground level railway would involve bringing everybody to Victoria station and leaving them to find their own means of transport for the onward journey. Workers at Heathrow could also use the underground line because a station could be built in the airport maintenance area, and fewer existing buildings would need to be demolished if the line were to go under the ground.

The London Transport scheme is favoured by British European Airways and the British Overseas Airways Corporation, but the British Airports Authority, which runs Heathrow, would prefer a British Rail link because of its belief that conditions on the underground line would be too uncomfortable. In the early morning overcrowding might be serious, because arrivals of transatlantic flights would clash with the heavy commuter traffic which makes tube travel unpleasant enough as things are. Getting baggage out of the underground trains at each station might lead to cumulative delays, and in any event the journey would be quicker by the non-stop services that British Rail has proposed.

SCHOOLS

Wooing Children to Science

by our Education Correspondent

ENCOURAGING more schoolchildren to opt for mathematics and for science subjects in the sixth form is a long-standing problem which has no easy solution. But this week the Joint Mathematical Council, the Royal Institute of Chemistry and the Institution of Chemical Engineers have published documents which might help to relieve the situation. On the one hand, the Joint Mathematical Council is concerned that mathematics teaching should be kept up to date and, on the other, the Royal Institute of Chemistry and the Institution of Chemical Engineers are concerned to improve the image of careers in chemistry.

The Joint Mathematical Council has published a statement on the present state of change in mathematics at secondary school level, in which it sets out the principles which underlie what it considers to be the best features of the new mathematics curricula. The aim of the statement is to provide a basis for discussion of so-called "modern mathematics" teaching. One problem is to decide what aspects of mathematics to teach, and to relate school curricula to recent advances in mathematics. But perhaps the most pressing problem is how to keep mathematics teachers fully informed of developments in teaching methods. The most effective way, the statement says, is to provide more facilities for in-service training.

The council believes that centres should be established in several parts of Britain, to provide in-service training on a regional basis. Such a centre is already operating in Nottingham, where staff from the University of Nottingham and from local colleges of education go out to schools to explain the thinking behind new courses. This approach, the council believes, is more effective than providing standardized courses for serving teachers.

Looming large over the council's thinking are the proposals for changing sixth form curricula and examinations. The council particularly wants to be sure that the proposals will not hold back the mathematically gifted child, and that they will not aggravate the shortage of mathematics teachers. It has set up a working party to consider the implications of the proposals for mathematics teaching, and the council will consider a report from the working party when it meets next week.

Improving the standard of teaching might help to attract students to mathematics, but perhaps the most effective incentive is the prospect of an interesting and highly paid career. It is with this thought in mind that the Royal Institute of Chemistry and the Institution of Chemical Engineers have launched a pamphlet which tells of the advantages to be gained from a career in the chemical industry. The pamphlet is aimed at children aged between thirteen and fifteen who, under the present system of specialized courses, will be taking crucial decisions about their future education. The Royal Institute and the Institution of Chemical Engineers believe that the need to convert more people to chemistry is so pressing that there is no time to wait for changes in sixth form curricula to take effect.

MEETINGS

Astronomers Meet at Brighton

THE Regency exuberances of Brighton will be echoing to talk of quasars and pulsars this summer. For the first time since 1925, the triennial general assembly of the International Astronomical Union is meeting in Britain, at Brighton and on the nearby campus of the University of Sussex. On the first and last days of the meeting, August 18 and 27, the administrative affairs of the union will be conducted, but the main business will be the meetings of the forty or so commissions into which astronomy has been successfully compartmentalized by the union. There should be plenty to talk about.

Commission 15, for example, is concerned with the physics of comets, and the members will be keen to discuss what to make of the vast hydrogen clouds which surround comets Tago-Sato-Kosaka and Bennett. Then there is commission 17, charged with lunar affairs, which has its hands full with trying to perfect a system for naming lunar features. At the last general assembly at Prague in 1967, hundreds of names were proposed for features on the far side.

As an antidote to specialization there will be invited discourses by A. Hewish and V. L. Ginzburg on pulsars, and by B. J. Bok and C. C. Lin on the spiral structure of galaxies, and a special meeting on the interpretation of results from Apollos 11 and 12.

About fifty countries support the IAU financially, but the union is almost unique in that the membership is made up of individuals who do not pay dues. More than half of the present membership of 2,000 are expected to visit Brighton for this year's general assembly.

MONGOLIA

Tidings from Ulan Bator

THE president of the Mongolian Academy of Sciences was in Britain last week to receive an honorary degree from the University of Leeds. The Snow line is not recognized in Mongolia, and the academy over which Professor B. Shirendev presides includes institutes of literature and history as well as of science. The natural sciences are studied in five institutes devoted to physics and mathematics, chemistry, biology and botany, geography and geology, and the academy also supports an observatory.

Modern science has only been studied in Mongolia since the revolution in 1921, but sciences such as astronomy have a venerable tradition, which was kept alive in the monasteries and other seats of learning. Besides the institutes maintained by the academy, the chief places of scientific study in Mongolia are the universities and the research institutes attached to particular ministries. Altogether the scientific strength of the country numbers about 2,000 research workers.

The budget for the Academy of Sciences is about 30 million roubles or £3 million. Professor Shirendev was unable to specify the total expenditure devoted to scientific research in Mongolia, but in any event his government is amply recompensed by the fruits of the research it supports. The Academy of Sciences is proud of its close links with scientists in other countries and that it numbers foreign scientists, such as Professor Owen Lattimore of Leeds University, among its members.

NUCLEAR PHYSICS

Prospects at CERN

AN important decision that is likely to confront the Secretary for Education and Science in the early months of the new parliament is whether or not Britain should back the revised version of the CERN 300 GeV accelerator project. Renewed pressure on the government is already mounting. As the first shot in the campaign, a group of leading British physicists signed a letter to *The Times* last week which urged the government to give the new proposals strong support now that the British balance of payments position has regained its health. The Science Research Council also disclosed this week that it has been considering the new proposals informally and greatly welcomes them. It is now awaiting detailed design studies for the new accelerator.

In the original 300 GeV scheme the goal was a clearly defined energy for which all parameters in the design were optimized. The cost was therefore well known in advance. In what may be called the creeping GeV plan put forward recently by Dr Adams, director of the 300 GeV project, the maximum energy can be increased in a series of stages. This means that at relatively little extra cost per GeV there is a guarantee of some value for money at each stage of expansion. Thus the initial expenditure for achieving energies up to 150 GeV would be about two thirds that for the original 300 GeV plan, but the incentive to go to higher energies would be very much stronger. The new scheme could turn out to be not only a way of making high energy physics more palatable to governments but also a means of ensuring the continued expansion of the subject if the research looks promising. Certainly if the development of superconducting magnets proceeds as well as is hoped, the demand for channelling more funds into high energy physics would become very strong.

There are, of course, other considerations which make the new proposals attractive. CERN has long been held as an example of how international collaboration can work, and the revised plan would remove the previous stumbling block of where the accelerator should be housed, as there would be room for it at the present site near Geneva. Moreover, the British Government would have to find a well chosen argument to fend off the claims of CERN for the second time in three years.

CONSERVATION

Burgeoning of Beavers

from our Soviet Correspondent

THE threatened beaver population of the Ukraine is now making a comeback. With the help of conservation measures and infusion of fresh stock the beavers have extended their range to the coasts of the Black Sea, according to a report from the Kiev Institute of Zoology.

The Ukrainian beaver was hunted extensively as a source of meat and fur throughout the historical epoch, from the time of the grand princes of Kiev (9th–13th centuries) until 1927, when the maximum beaver population of the Ukraine was estimated as being less than 80 individuals. Strict conservation laws were at once introduced and in 1934–35 some restocking was carried out. Canadian beavers were

introduced on the headwaters of the Horyn. Unfortunately, the beaver population of Ukraine was once again almost wiped out, this time by the military operations of the Second World War. The Zhitomir and Kiev regions were restocked with some 50 animals from Byelorussia in the early post-war years and by 1965 the total beaver population of Ukraine was estimated at 2,000, situated, according to the *Ukrainian Soviet Encyclopedia* (vol. 17, 1965) on the Dnieper, Teperev, Pripyat, Desna and Horyn rivers, the greatest concentration being on the areas newly flooded in connexion with the construction of the Dnieper dams at Kiev and Kaniv. Further expansion of the beavers' range is being assisted by careful trapping and subsequent release of suitable specimens (numbering some 400 to date) into rivers with no surviving indigenous population. This resettlement, together with the natural expansion of the population (in a general southward and eastward direction), gives the beavers a more promising future than they have had for many years.

EXAMINATIONS

More Evidence against A-Levels

UNIVERSITIES should not select their students on the basis of 'A' level results alone, and other criteria, such as a student's outside interests, his headmaster's report, and his attitude to his future career, should be given much more weight in the selection process than they are at present. These conclusions, drawn by P. R. Freeman of University College, London, are based on an analysis of the performance of students in first year examinations at the University of Reading (*Journal of the Royal Statistical Society*, **133**, 38; 1970).

The variables used in the analysis were the results of questionnaires designed to measure students' intelligence, motivation and personality, and also taken into account was an autobiographical sketch in which the students were asked to imagine they had just reached the age of sixty. There were also seven scholastic variables including 'A' level results, 'S' level results and headmaster's report. 'A' level results turned out to be the best single indicator of university performance, but the headmaster's report, the student's projective autobiography and some personality factors also proved to be valuable guides to his academic ability as measured by university examinations. But admissions tutors should be wary of using intelligence tests and personal interviews as a basis for selection because, according to Dr Freeman's analysis, none of the chief components of a student's psychological "make up" are strongly associated with his academic ability, and intelligence tests are not a very useful guide.

These findings, which broadly agree with those made by D. G. Bagg from a study of the performance of engineering students at Manchester (*Nature*, **225**, 1105; 1970), should be seen as strong grounds for eschewing the emphasis on 'A' level performance for university selection, Dr Freeman suggests. Such a change in emphasis, and its effect on sixth form syllabuses, would be most welcome to the advocates of broader sixth form curricula, and improved ability to predict a student's performance could also be used to provide an early warning if his standards start to fall.

Dr Freeman is careful to point out that there are many possible variables not included in the analysis. For example, the content of degree courses and the quality of the teaching would be expected to influence a student's performance and there is, in any case, no guarantee that university examinations are the best method for assessing a student's ability.

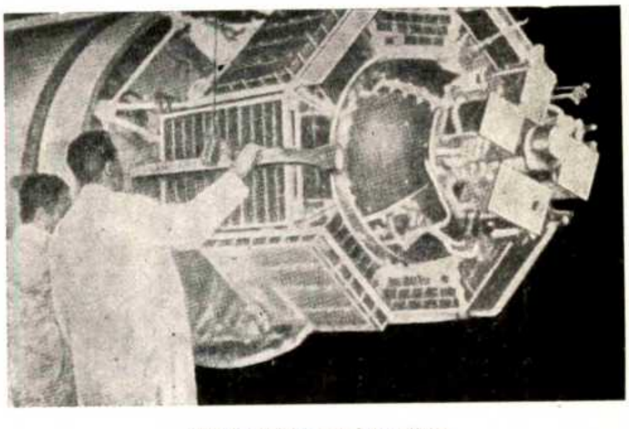
SATELLITES

Polarized Bursts

from our Soviet Correspondent

AN interesting feature of the conference now being held by the Committee on Space Research (COSPAR) in Leningrad is the publication of the preliminary results of the experiments performed by the first of the Interkosmos series of satellites (see *Nature*, **225**, 117; 1970). Interkosmos–1, launched on October 14, 1969, carried instrument packages provided by Czechoslovakia, East Germany and the Soviet Union, designed to measure the ultraviolet and X-ray radiation of the Sun and its effect on the upper atmosphere. The satellite had a perigee of 240 km and an apogee of 640 km.

Among the preliminary results, observations of solar bursts between October 20 and 30, 1969, indicate that the X-ray emission from solar bursts is partially polarized, the coefficient of polarization varying as the burst develops, which is evidence that this radiation is not purely thermal in origin. A correlation between the X-radiation from bursts and processes in the lower ionospheric has also been observed, which, of course, is known to have considerable significance for long-wave broadcasting.



The Interkosmos-I satellite.

Other results include data on the composition of the upper atmosphere (obtained by absorption measurements with a Lyman-alpha photometer) and optical photometer determinations of the density of aerosols produced in the upper atmosphere by meteoric dust. (The exact figures for these experiments are yet to be published.)

Interkosmos–1 had an orbit very close to those of the Earth satellites Kosmos–166 and 230 which observed the Sun. It is expected that when the complete data of Interkosmos–1 are published, they will include not only the results of the Russian, Czech and East German experiments but a comparison with the data obtained by its two Kosmos predecessors.

UNITS

Going Metric in Britain

THE Metrication Board published its first report earlier this month (*Going Metric—The First Five Years*. HMSO, 12*s* 6*d*). Professor M. L. McGlashan, a member of the board, writes as follows:

The changeover from imperial to metric weights and measures throughout the whole of Britain's industry, commerce, and everyday life had been set in motion by the government in 1965, with 1975 as the target date for its substantial completion. The Metrication Board was appointed just a year ago to catalyse the changeover. When the Board began its work much had already been achieved: by the British Standards Institution, especially in the preparation of metrication programmes for various sectors of industry, by government departments, by the professional and trade associations, by the Industrial Training Boards, by educational associations of all kinds, and by many other institutions, firms, and individuals. Metrication was on its way; the point of no return had already been reached. It remained to be seen only how efficiently and quickly it could be carried through; for, by and large, the earlier and more thoroughly it has been planned and the more quickly it is then done, the lower will be the cost. The Board's task was first to inform itself and then to inform others; to help and encourage the leaders and to prod the laggards; and to identify stumbling-blocks and see that they were cleared from the path.

Typically the Board would find that metrication was going well in all except one of a group of similar industries. In that industry the stumbling-block was (say) metric "bobbles". The Board would be told by the firms consuming bobbles that they were anxious to go metric but could not obtain metric bobbles from their stockists. The Board would be told by the stockists that they were unable to obtain metric bobbles from the manufacturers, and that in any case there was no demand for them from their customers. The Board would be told by the manufacturers that they were ready and willing to supply metric bobbles but that there was no demand for them from the stockists. It is the Board's job to solve such puzzles.

One of the early tasks of the Board was to resolve some confusion about just which units were implied by the word "metrication". This task was greatly helped by a statement by the Minister of Technology in the House of Commons on July 24, 1969, that the International System of Units (SI) was accepted by the government as the basis for the changeover to the metric system. In particular the Board has been at pains to correct a view which had unfortunately gained ground that the centimetre should no longer be used, and even that it was not a unit of the International System, or at best a second-class one or a kind of baby-talk. This view arose from the internationally agreed recommendation of a preferred selection of multiples and sub-multiples of the SI units, excluding the centimetre, for use in industry by technicians, for example, in drawing-offices and on the workshop floor. That recommendation had never been intended to apply to science, or to trade and commerce, or to everyday life; and certainly not to education—except in the most specialized technical training.

The Board's hope that no child starting school after the autumn of 1969 would ever again be exposed to the imperial system as his or her "first language" of measurement has largely been realized. In other spheres of education a good start has also been made. Most public examinations will be fully metric (SI) by the summer of 1972 and the rest very soon afterwards. The educational publishers and manufacturers of educational equipment are responding nobly to the demands made on them by the teachers.

In all other sectors of the economy and national life metrication is either being rapidly implemented, as in the construction and engineering industries, or has been realistically and fully programmed; for example, the statutory speed limits on roads will be changed to round numbers of km/h in 1973.

The Board now faces the rapidly expanding task not only of catalysing all these changes but also of informing the public in good time about them, a task which will reach its peak as, beginning in 1972 and accelerating in 1973, metrication begins to appear in the market place: in the measures used for the sale of petrol and coal and gas and of butter and milk and beer.

The Board does not pretend that metrication can be achieved without cost, but emphasizes that no meaningful estimate has been, or can be, made of the total cost; or, for that matter, of the financial gains to be expected, not only from metrication itself in terms of trade with the rest of the world, but also from the standardization and variety-reduction with which it will so often go hand-in-hand. Case histories of a few individual firms which have completed the change suggest that the cost of the necessary investment is a good deal less than had been feared and that the return is quick and considerable.

Ten Universities Too Few

by our Education Correspondent

THE number of places which existing universities can reasonably expect to provide by 1980 is about 50,000 short of what the government wants. This warning, contained in a statement published last week by the Committee of Vice Chancellors and Principals, is based on estimates sent in by individual institutions of how far they could expand if the necessary resources were made available. It was also accompanied by the message that all but one of the government's suggestions for reducing costs are unacceptable to the universities. This will be cold comfort to the Department of Education and Science, which has been trying to find ways of accommodating the demand for higher education as cheaply as possible.

The universities' estimates are based on the particular circumstances of individual institutions and also, it seems, on the assumption that there will be no major changes in the length of courses or in the relations between the universities and other institutions of higher education. The universities reckon that about 400,000 full-time student places is about the most that they can hope to provide by the end of this decade. The Department of Education and Science, on the other hand, has worked out that if 53 per cent of the school leavers with two or more A-levels are going to get into university in 1980, about 450,000 places are required. If the extra places are not found, universities will be forced to put up their entry requirements, and to turn away more and more good students. Opportunities are, in fact, already being reduced because universities are now taking only 49 per cent of qualified school leavers compared with 53 per cent in 1963.

What, then, is to be done? The shortfall could, of course, be taken up by establishing some new universities, but even if this were done almost immediately it would require at least ten new institutions to provide the required capacity by 1980, and Mr Short has already hinted in a written reply that the government has no definite intention of following such a course. The answer therefore seems to lie in some restructuring of the whole higher education system, and the vice chancellors have cast an eye on the colleges of education. But they have been careful not to be too presumptuous because sweeping changes in the system require long study, and in any event it is not their place to make recommendations about other institutions. At the centre of their thinking is the possibility of introducing two-year courses of study to a sub-degree level. This is, in fact, the only suggestion for reducing costs which has been canvassed by the government and which the universities believe requires further study. But they see it as more of an educational measure than a short-term way of saving money.

Such courses could take one of several forms. One suggestion is that they could be given in modified colleges of education to students who could be expected to reach the limit of their academic ability after two years of study. On the other hand, some universities believe that there might be scope for reviewing the university course structure in a way which would permit a basic two year course to be followed by one or two years of study for those wishing and able to proceed to a specialist honours degree or to a higher degree. The two year course could, in this case, be given in a modified college of education associated with a particular university.

Such two year courses are not a new idea. They were suggested by Professor Brian Pippard in the Swann Report in 1968 and again this month in an article in the *Cambridge Reporter*, and there seems to be an influential lobby developing in the vice chancellors' committee for changing the role of the colleges of education. Dr F. S. Dainton, vice chancellor of the University of Nottingham, for example, has suggested that colleges of education should be turned into liberal arts colleges, providing courses to a first degree level from which students could proceed to more specialist courses at the universities (see *Nature*, **226**, 490; 1970). Such a development would, of course, require stronger links to be forged between existing colleges of education and the universities.

A more intractable problem is how the polytechnics are going to develop during the next decade. The government has staked many of its hopes in the polytechnics, and has provided for a rapid expansion in their capacity during the 1970s. But their role has not been clearly worked out. The vice chancellors statement drew attention to the possibility that there will be wasteful duplication of resources if they develop along the same lines as the universities, but, on the other hand, the universities are chary of suggesting that there should be a unified system of finance and control of all higher education institutions. Such proposals, they argue, require much deeper study. But there seems to be general agreement that stronger links must be forged between the polytechnics and the universities and, in Dr Dainton's plan, some polytechnics would be directly affiliated with the universities while others would develop along similar lines to the colleges of education.

As far as cost saving is concerned, the universities have rejected the government's suggestion that they could be more restrictive in admitting students from overseas, that grant-aided students might be required to enter specific types of employment, and that a loans system might replace the present system of maintenance grants for students. All these proposals, they argue, would be socially unacceptable and, in any case, they would not save very much money. The suggestion that some universities should take the bulk of their students from surrounding areas is also unacceptable because students living on the fringes of the "catchment area" would have to spend too much time travelling, and because living away from home is, in many cases, a good maturing influence. The vice chancellors' statement also pointed out that capital grants for residential accommodation have fallen sharply over the last few years, and much greater savings might arise from loan-financed student housing schemes.

One suggestion that the universities are particularly anxious about is that student numbers might be allowed to increase at a greater rate than the number of staff. Because staff salaries form the largest portion of recurrent costs in the universities, such a measure would result in considerable savings. The vice chancellors' answer is that, although there may be a few departments where some change could be made in the staff/student ratio, they would be very reluctant to see it altered to any great extent. For one thing, close personal contact between staff and students, which is only possible if the staff/student ratio is small, is a particular hallmark of British universities, and it is essential for maintaining the standards of university degrees. In any case, the vice chancellors argue that the growth in numbers of full-time staff has not kept pace in the past few years with the growth in student numbers, and the staff/student ratio is therefore already under pressure. And there is little prospect that the universities will have enough money during the remaining years of the present quinquennium to halt this trend.

The government can, however, take a few crumbs of comfort from the universities' obvious intention to do all they can to expand. But the vice chancellors' statement pointed out that a growth rate of some 6 per cent a year would require a government decision to devote a higher proportion of the national product than hitherto to higher education. Such a decision, the statement said, "would be both right in the interests of the nation, and inescapable in view of the prospective demand".

NEW WORLD

No Boom for Atomic Energy

THE Joint Committee on Atomic Energy, the watchdog of the Atomic Energy Commission, has deserved its reputation with the commission's firmest friends by recommending a budget authorization which is \$7·7 million more than the \$2,283 million for which the Administration had asked in February. Without dissent, the budget passed through the Senate and the House of Representatives a week ago, although it remains to be seen whether this larger sum of money will actually be appropriated for the coming year and whether, if it is, the AEC will be allowed to spend it. Those who will have been impressed with the evidence given to the committee about the effect of some of the Administration's policies on the ability of the AEC to support basic research in the physical sciences will no doubt be disappointed that the joint committee has nothing to add to these items in the Administration's budget.

If there is no extra money, however, the committee does have something to say about the consequences of the Atomic Energy Commission's new attitude to basic research. In the year ahead, the commission's expenditure on physical research will be \$274 million, a decrease of \$3·75 million from the preceding year. In addition, the AEC has asked to spend in the coming financial year a total of \$119 million on capital projects, chief among which is the 200 GeV accelerator—now to be made capable of accelerating protons to 500 GeV. The joint committee says that the decision during the coming year to "start to phase out" the proton accelerator operated jointly by Princeton University and the University of Pennsylvania and which has been, according to the joint committee, the mainstay for high energy research for fifteen university groups in the past five years, is most disturbing. The joint committee goes on to say that the shutdown should be postponed at least until the universities can find the money to keep on operating the accelerator, in which light it is more than a little surprising that the joint committee offers no extra money.

In other parts of the physical research programme supported by the AEC, the committee says it is concerned that there is nothing in the 1971 budget for the building of high energy particle storage rooms comparable with those at CERN, saying that the result will be that increasing numbers of American scientists will try to carry out work at facilities abroad, to the detriment of what they undertake in the United States. One of the fields in which the AEC proposes to increase its rate of expenditure is in medium energy physics, chiefly in connexion with the Los Alamos meson physics facility, but the committee takes the view that the plan to build into the machine facilities for biomedical research some time in the future should be paid for with other funds. Without recommending extra money, the committee has also shaken its head over the reduction of expenditure on low energy physics, chiefly by the shutting down of Van de Graaff accelerators at a number of universities. In spite of the enthusiasm of the AEC for thermonuclear research based on variations of the Russian Tokamak devices described in the past year, the joint committee believes that there is still much to be gained from a study of other types of thermonuclear machines and hence it has lopped off \$1 million from the AEC's request.

The joint committee has dealt with other parts of the AEC's programme for 1971 with similar care. One of its more vigorous decisions has been to ask the AEC to spend more effort on the development of liquid metal fast breeder reactors, which is "of the highest priority". The joint committee says that it would like to see more interest in industrially sponsored reactor projects and fears that the amount of money allocated for helping such work along is insufficient. In the coming year, the AEC is planning to spend \$43 million on liquid metal fast breeder reactors, mostly at its own establishments, but something like \$7 million is also being spent on the definition of prototype reactors. The joint committee is doubtful of the significance of this work and has attached to the authorization bill a requirement that the Atomic Energy Commission should give it 45 days in which to consider and approve of proposals for collaboration with industrial companies for the building of experimental reactors. In general, however, the committee does urge that the AEC should build itself a breeder demonstration plant without delay.

The other amendments to the Administration's request for funds recommended by the joint committee spring from its belief that more needs to be done to build up stocks of fissile material for military as well as civil purposes. In particular, the committee quarrels with the AEC's proposal to close one of the two reactors at Richland, Washington, which has been used for the manufacture of plutonium for the best part of two decades; it fears that the remaining military reactors—one at Richland, two at Hanford and three at Savannah River—would not be able to meet a sudden increase in the demand for nuclear explosives that might arise from the antiballistic missile programme now under way. It also asks that the AEC should be allowed to begin work on what is called the Cascade Improvement Program by means of which it has been suggested that the output of enriched uranium from gaseous diffusion plants could be substantially increased. One of the committee's anxieties is that at the present level of operations, it will be hard for the US Government to honour its promise that enrichment services will be available to all qualified customers, in the United States and elsewhere, at a reasonably low cost.

Much of the joint committee's commentary on the AEC's proposals for 1971 is linked with the current preoccupation with the quality of the environment. Several parts of the proposed budget have been increased by modest sums of money. Thus the committee urges the expenditure of an extra \$140 on the food irradiation programme, chiefly so that the commission can carry out more careful studies of the mutagenicity of irradiated foods before applying to the Food and Drug Administration for permission to use them experimentally.

Decision-making on Massachusetts Avenue

from our Cambridge Correspondent

HARVARD and MIT, at opposite ends of Massachusetts Avenue, have had their share of problems in the past year or two. Some have been those of all the thinking campuses of the United States—attitudes to war in South-east Asia, new directions for research into the issues of industrial society and questions as to the political responsibilities of a university. But some have been distinctly their own. Two such which have just surfaced are those of defence related research and whether to support the campaign to make General Motors more socially responsible.

The GM issue has had to be faced by universities and other bodies all over the nation, but the votes of Harvard and MIT (600,000 of 280 million), if cast in favour of Campaign GM's proposals, would have carried more weight than 10 million in most other places. The complex and often incestuous relations between the governing bodies of Harvard and MIT and that of GM have made the decision the more ticklish and the outcome perhaps the more inevitable. Neither voted in favour of the campaign.

This came as a shock to many of the eastern liberals who have been pleasantly surprised to see august institutions gaily distributing academic time to teach-ins, teach-outs, walks, canvasses, rallies and strikes on the Cambodian issue. Indeed, the attention that has been focused on Cambodia has taken quite a lot of the steam out of the apparently more mundane issue of bringing the mammoth corporation to heel, while the general dispersal of students at the end of their term has made it easier for the decision to be taken without bricks being thrown through treasurers' offices. In hindsight, it is clear that students have put too much emphasis on the next to impossible—shifting middle America—instead of the not improbable—embarrassing an unloved giant.

University investment policy has never until now been a wildly exciting issue (the Church of England has more experience of unfortunate financial involvement in the nineteenth century). But universities which like to regard themselves as centres of enlightenment ought also to be spreading this enlightenment into some regions where they have an unusual opportunity to make their voice heard. Of course, Campaign GM was bound to fail first time round, but there should be no stigma for a university in backing a loser. One suspects that although executive committees charged with the job of deciding how to vote were scrupulous in excluding from the decision making anyone with a direct interest in GM, they are bodies too tight knit to break ranks entirely with their colleagues.

The statement issued by MIT's Executive Committee bears examination. It had received strong representations from official channels to support Campaign GM, but eventually decided by an "extremely narrow margin" to vote against the proposal to enlarge the board of the corporation. After conceding that the constitution of boards of large corporations is an appropriate matter for public concern, the committee declared, however, that it could not reach agreement that the proposed addition of three to represent consumer interests would be better than leaving the board at its present size. It agreed, however, that there ought to be a greater diversity on the board than there is at present and gave General Motors the gratuitous advice that it should add new members or inject new blood. The difference between taking this stand and supporting Campaign GM is subtle if it exists at all. Perhaps the argument whether there should be 23 or 26 on the board was just a debating point to enable the committee to get itself out of an embarrassing corner. It knows full well that in company affairs, votes are what count; the best way to hide support for the status quo is to give apparent moral support and praise to the opposition.

An equally thorny issue came up with President Howard Johnson's statement to the MIT faculty on Wednesday, May 20, of his decision about the relationship of the institute to the Special Laboratories. The care with which the problems of Lincoln Laboratory and Draper Laboratory have been considered is remarkable at a time when many universities were happy to rid themselves of defence laboratory commitments at the sight of the first radical on campus.

The issues were basically these. Draper Laboratory (formerly Instrumentation Laboratory), situated in the middle of the MIT campus, has an unrivalled pre-eminence in inertial guidance systems. It has held contracts for Poseidon developments, and much of the MIRV technology springs from the expertise of the laboratory and the singular Dr Charles Stark Draper. At the same time, the Draper Laboratory justifiably gets the credit for the remarkable accuracies of navigation in the Apollo missions. Beyond that, its capabilities are only those of any thoroughly competent industrial contractor. Its staff are distinctly more patriotic than is fashionable these days in Cambridge, Mass.

Lincoln Laboratory lives twelves miles out and has a much broader base. It has no presiding genius, its staff are lukewarm to MIT (one member epitomized it by describing his relations with MIT as hitting a monthly high when he sees the magic words on his pay-check), but it has a much more stable base. Words like data, systems, networks, processing, hardware and software—the magic currency of the present—tend to evoke favourable responses at Lincoln. The Department of Defense has repeatedly used the pool of expertise in Lincoln to initiate new projects, although these have been dominantly defensive rather than offensive.

MIT operates both laboratories and so has a very large pool of talent, unlike that of almost any other educational establishment, under its ultimate authority.

An analogy is bound to be incomplete, but it is as if the University of Reading had the Royal Aircraft Establishment at Farnborough under its wing.

The decision which President Johnson took on himself last year was to come to a conclusion within less than a year on whether such attachments were appropriate. The further restraints were that the Executive Committee had barred work on systems for operational deployment as weapons and that financial support had to be forthcoming for any diversification. Add to this the ingredient that MIT, by acting as host to these basically contract laboratories, receives about $8 million annually for administration overheads at a time when the institute is beginning to go into the red, and it appeared that Dr Johnson had a variety of fairly unpalatable options and no easy way out.

His personal standing among most people is, however, high, almost unique for university presidents, and his unassuming nature has probably helped where rhetoric has failed. Another unusual ability in a nation that lives on press leaks is his skill in keeping a secret. Three days before the meeting "informed sources" had told the *Boston Globe* that MIT would keep the laboratories. When he announced his decision, it was that Draper Laboratory would have to go.

The rationale was simple. The styles of the two laboratories differ, and Draper could not stop work on weapons without carnage to the laboratory and its employees. There is insufficient demand for civilian inertial guidance to guarantee the same level of employment, and dismantling the expertise accumulated for a very specific purpose would perhaps ruin the laboratory. As Johnson saw it, forcing the Draper Laboratory away from its present objectives would not work, so immediate steps are being taken to move the laboratory first to being an entirely separate entity of the institute and then, within a year, to being a separate corporation whose ties with MIT would be no greater than those of the many organizations spun off from MIT and Lincoln in the past.

Lincoln Laboratory, with a greater potential for diversification, stays with MIT and defence related research continues, although the need for the declassification of projects and closer educational ties is emphasized. The development of the relations between the mission oriented laboratory and the institute is going to be an object of great interest in the next few years. Whether the Department of Defense will change its funding levels in any significant way and whether Lincoln can attract substantial money from outside, only time can tell. Inspired guesses about finance are few these days with the American financial situation so worrying.

It is early to gauge yet what response the decision to divest the Draper Laboratory will have from those most vociferous in demanding changes. The most strident demands were that the institute retain control and stop war research and among such people there will be bitterness that in years to come the Draper Laboratory will be indistinguishable from most other members of the military industrial complex. However, little constructive advice has been forthcoming about how Draper's expertise can be used to solve America's domestic problems. It looks very much as if Howard Johnson's decision is the least of the possible evils and is probably as little self-destructive as any decision could be under these circumstances.

AIR POLLUTION

Down with Sulphur Dioxide

A COMMITTEE of the National Research Council, set up last year in response to a request from the Department of Health, Education and Welfare, has now published a proposal for a five-year research programme intended to provide ways of reducing concentrations of sulphur dioxide in the atmosphere. High on the committee's list of suggestions is that there should be more research on methods of removing sulphur dioxide from waste gases, principally the exhausts from central power station boilers. The committee was driven to this view by its discovery that there is at present no "commercially proven technology for controlling sulphur oxides", and it goes on to say that in the present state of technology, it would be unwise to force widespread use of unproven processes. This opinion will be something of a blow for the government agencies at present seeking to encourage the adoption of devices for removing sulphur dioxide from power station exhausts.

The committee argues that if present tendencies were to continue, the amount of sulphur dioxide released into the atmosphere in the United States would be four times as great as at present by the year 2000. The forward projections for electricity production in the United States suggest that the total generating capacity will amount to one million MW by 1990, more than three times as much as at present. Coal and oil will be used on an increasing scale until well after the year 2000, although nuclear generating capacity will be greater than that of coal burning stations before the end of the century. In other words, nuclear energy production will not prevent an increase in sulphur dioxide production from generating stations in this century, especially because the increasing use of low grade coal implies that more sulphur is released. Indeed, by the end of the century, it is calculated that 125·8 million tons of sulphur dioxide will be released to the atmosphere from United States industrial operations, close on 80 per cent of it from power stations.

The committee has evidently spent much of its time wondering whether the best way of controlling sulphur dioxide in the atmosphere would be to accelerate the development of nuclear power stations and particularly the breeder reactors without which rapid development would not be possible. Not surprisingly, it comes to the conclusion that this would be to put the cart before the horse. So what can be expected of the technical devices at present offered as means of controlling sulphur dioxide emission ? Although it is possible to remove sulphur from fuel oil, the committee calculates that reducing the sulphur content from 2·6 per cent to less than 1·6 per cent would entail an increase in the cost of fuel of between 20 and 35 per cent, the equivalent of 0·7 mills (1 mill=1/1,000 of a dollar) per kW hour. The notion that it might be possible to remove sulphur from coal by washing is a greater surprise—the committee estimates that coal cleaning could remove all but 1 per cent of sulphur from a quarter of the most heavily contaminated coal and 40 per cent of the sulphur in the rest of the coal used for power generation could be removed by washing processes costing as little as 25 c per ton of coal. In the past few years, most attention seems to have been given to methods for removing sulphur dioxide from stack gases, and the committee has examined 25 of these being developed in the United States as well as a number of methods being tried out elsewhere in the world. It says that only one of the processes has so far been installed in a large commercial installation, and it concludes that there is an urgent need for commercial demonstration plants, presumably supported with federal money, to test the feasibility of the more promising devices, probably at a cost of several million dollars. Among the committee's favourites are the limestone processes for removing sulphur dioxide—processes along these lines have been tried out in Britain since the 1930s, but it seems to be agreed that their efficiency and effectiveness leave much to be desired.

STUDENTS

Origins of Abuse

from a Special Correspondent

Palo Alto, California

President Nixon's disastrous description of American students as "bums", which has united both university staff and students against him, seems to have sprung from a single incident in his home state, California, and on a single individual's special pleading. The evidence for this is now clear. The fire that prompted the remarks did not even take place at a university and there is no incontrovertible evidence that it was caused by students.

During the momentous last week of April (when the President took the Cambodian decision), he received a letter from an American professor on a year's leave of absence for private research at the Center for Advanced Study in the Behavioral Sciences. The centre is an independent institution providing seclusion for internationally selected scholars in the social sciences. It is paid for by the Ford Foundation and located on a woody hilltop on Stanford University property. It has no other links with Stanford or any other university. The letter to President Nixon presented a rather exaggerated account of an arson attempt on the centre when it was deserted the previous weekend (Friday, April 24). It also described how as a result the fruit of a distinguished Indian anthropologist's 22 years research on a multi-caste village in southern India had gone up in smoke. The writer also speculated on the identity of the fire raiser or fire raisers, though the culprits were unknown and remain so.

Another American fellow at the centre, Professor J. Bunzel, who had been active against campus radicals at nearby San Francisco State University, denounced the incident on television as a personal attack by radical students against himself. He had not in fact suffered in the fire, which was rapidly controlled, causing damage to the studies of only three out of fifty fellows.

The principal victim, Professor M. N. Srinivas of the University of Delhi, has been most careful not to lay blame in any quarter, and certainly not on protesting students. The evidence is simply non-existent. There is evidence that the fires were caused deliberately (two took hold), but it seems unlikely that the arsonist will ever be traced.

In his letter of condolence to Professor Srinivas in the last week of April, President Nixon firmly pinned the blame on dissident student elements. "To say they are simply evil does not make them go away." As Professor Srinivas freely admits, this has made it difficult for him to reply to the President without discourtesy. He achieved it on April 29.

A week after the exchanges with the President, and after his remarks on May 1 about "bums burning up books", and when it emerged that the incident at Palo Alto centre had achieved a notoriety out of all proportion to its significance, a letter signed by 33 of this year's 45 resident fellows was sent to the local newspaper, the *Palo Alto Times*, attempting to put the record straight.

The damage to Professor Srinivas's original material has proved less catastrophic than first supposed. About two-thirds of the data burned can be reconstituted by emergency measures already in hand and the rest is being replaced from India, and a research assistant is being specially flown in to help the professor. "I feared he would have to spend a further decade reworking his material," the centre's acting director, Dr Preston Cutler, said last week. This can be avoided. Dr Cutler's ultimate concern has been damage to the centre's principles of operation. "Our self image has always been wide open, hospitable and safe." Now the centre has armed guards on duty 24 hours a day on its open gates.

POPULAR ENTOMOLOGY

Year of the Locusts

Washington is now facing with some surprise an infestation of the periodic cicadas—popularly known as the seventeen-year locusts. The last severe onslaught of these insects was in 1953, and this one is being borne with some fortitude because the next will not be until 1987. The locusts have an extended life cycle in which the females each lay some 400–600 eggs in the branches of trees during June, and shortly after the birth the worms burrow underground to remain there for the next sixteen years and ten months. The males emerge from the ground first, climb up into the trees, and begin to sing after some four to five days (a high pitched humming which now characterizes the countryside around Washington) to attract the later emerging females, which then lay their eggs to restart the cycle.

Unlike the more commonly known and feared virulent locust, the cicadas—about an inch and a half long with large translucent wings—are harmless to man and only indirectly harmful to vegetation. They do not eat the leaves of plants in their short lifetime above the Earth, and their only deleterious effect upon the local ecology is the damage caused to the branches of trees by the holes punched by the females during egg laying. Although this can be a serious commercial problem for orchards, it is not more widely damaging.

Although Washington can expect relief from locust infestation for more than sixteen years, some areas of the American continent will suffer each year, for there are seventeen "broods" of periodic locusts, one for each year. Each brood seems to be part of the same species. But because any particular brood appears above ground only in its characteristic seventeenth year, it is reproductively and ecologically isolated from the others. The cycle seems to be maintained with high regularity and the occasional stragglers which emerge a year too early or too late usually die. Also assisting their ecological isolation, the different broods have different preferred areas; this year's brood (number X) is the most numerous and the widest ranging, being found in an area bounded by the Great Lakes in the north, New York in the east, Virginia in the south and Mississippi in the west. Three other broods will also be seen in Washington (XIV, due in 1974; II, due in 1979; and VI, due in 1983), but none so fiercely.

All in all, locusts are probably a little more complicated than just a single species divided into seventeen yearly broods. More recently, it has been suggested that there may be some six distinct species of periodic cicadas, each existing as a pair-species. That is, each may have broods with both seventeen and also thirteen year cycles. In that case, there would be a chance for the different broods to mingle, presumably one year in 221, when the thirteen year and seventeen year cycles coincide—but this is not due again until the twenty-second century.

The seventeen year cycle of the locusts was known to the American Indians and was first studied before the beginning of this century—the first brood was numbered in 1893—but this system has been subjected to surprisingly little scientific study in recent years. It provides, after all, an unparalleled opportunity to study the differences which there may be between the gene pools of a single organism existing in different ecological niches, but with the unusual factor that these niches are not necessarily separated geographically, but may be only temporarily distinct. That is, apart from year to year differences in climate, some of the various broods have the same ecological environment.

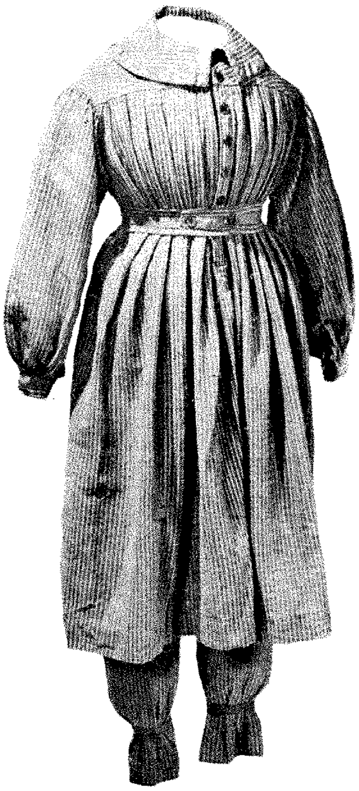
Another intriguing problem is that of how the insect maintains itself in what must be essentially a metabolically inert state for almost seventeen years. But perhaps it is not so surprising that little is known about how the locusts maintain their reproductive cycle with such unfailing regularity, for, after all, one research scientist can fit only two, at most three, locust cycles into his working lifetime.

FASHION

Swimming for Freedom

It is not just a matter of physical relief that the present 1920s look in women's clothing fashions has not been extended to swimming costumes. In any case, the evolution from the bathing costumes of those days to the contemporary garment demonstrates the metamorphosis of woman from the subordinate weaker sex to the "equal and active member of society" she is today. This at least is the thesis of Claudia B. Kidwell of the Smithsonian Institution, who has compiled a historical survey of the female bathing costume in the United States (*Contributions from the Museum of History and Technology*, p. 169. Smithsonian Institution Press, 1969).

It was the rise of the Christian Church that spelt the demise of the social aspects of bathing as practised by the Greeks and Romans, and it was not until the seventeenth century that women re-entered the water, and then only in small numbers. During the eighteenth century bathing became slowly more popular as the health-giving properties of water began to be emphasized, and by the 1800s women were being encouraged to swim. Bathing houses sprouted up wherever springs could be found, and bathing in the sea became an established pastime. However, throughout this period women paddled rather than swam and the bathing costume was designed more for adornment than use, besides which modesty demanded that it should cover every part of the female form.



Bathing dress of about 1855 (Philadelphia Museum of Art).

By slow degrees comfort as well as fashion crept into the styles until by the 1850s women were allowed to reveal themselves as bipedal, the original shapeless chemise-type gown giving way first to lace-edged pantaloons, and later to knee-length drawers worn beneath a long overdress. The skirtless bathing suit was next on the scene, but won greater popularity in Britain where bathing was segregated than in the United States where it was mixed. By the 1870s short-sleeved, low throated suits were being made and, as the century progressed and women grew more daring in the water, functional styles continued to advance. Costumes became more streamlined, trousers became kneelength, and by the beginning of this century freedom was on its way.

During the 1920s the swimming suit as opposed to the bathing suit gained ground, a trend accelerated by a growing advertising and ready-to-wear clothing industry. Women began to take the sport seriously, and though prejudice was rife a swimming costume almost recognizable as such began to take shape. When in the 1930s the desire to obtain a suntan forced costumes to become briefer and briefer, the marriage of style and utility was slowly but surely taking place. With the bikini the bathing costume has, of course, reached, if not its *ne plus ultra*, at least the end of an absorbing evolutionary track.

NEWS AND VIEWS

Swings and Ribosomes

ON the whole the followers of molecular biology have little difficulty in picking the winners. But occasionally they find themselves in the same invidious position as punters betting on a two-horse race contested by runners with comparable pedigrees and the same trainer. In the past two weeks just such a situation has developed over the question of which elements of the bacterial translation machinery recognize the different initiation signals in messenger RNAs that tell ribosomes where to start synthesizing proteins.

Undoubtedly in the first step of the translation of the information coded in a messenger RNA into the sequence of amino-acids in a protein the small 30S ribosomal subunit recognizes and binds to a specific initiator sequence in mRNA. Once this has happened formylmethionine, the initiating amino-acid, is carried by its specific transfer RNA to the complex, then the 50S ribosomal subunit is added and synthesis of the protein can begin. Clearly the specificity of this initiating process resides in the first step, the recognition of the initiator sequence by the 30S subunit. But only in the past six months has the degree of sophistication of this recognition process become apparent.

Last December (*Nature*, **224**, 957; 1969) Steitz reported that the three genetic messages which are contained in the RNA of the RNA coliphage R17, and specify the three phage proteins, begin with three different initiation sequences. The 30S ribosomes of *E. coli*, the host of these phages, obviously must be able to recognize these three start signals. Moreover, because the three phage proteins are not made in equimolar amounts in infected bacteria or cell free systems, the ribosomes must be able to discriminate between the three signals. Such discrimination, of course, provides cells with another point at which gene expression can be regulated, but how is this achieved?

One obvious possibility is that the ribosomes have permanently built into their structure the capacity to recognize specifically one particular initiation sequence. Alternatively a factor (or factors) might transiently associate with the 30S ribosome at initiation and temporarily confer on it the necessary specificity. This mechanism has the great advantage of flexibility. It does not force the cell to commit permanently its ribosomes to any particular start signal. Moreover, there is a precedent for mechanisms of this type. Sigma factors transiently associate with RNA polymerase and confer on it the ability to recognize particular sequences in DNA which signal where RNA synthesis should begin.

Knowing that *E. coli* ribosomes can discriminate between three initiation signals, and with the sigma factor precedent in mind, the stage seemed set for a series of elegant experiments proving that initiation factors regulate the selection of start signals in messengers. Of the three initiation factors in *E. coli* f3, the factor required for the translation of natural but not synthetic messengers in cell free systems, seemed the best candidate for the job. Some of the anticipated experiments have duly been done by Dube, Rudland and Steitz (see pages 820 and 824), but Lodish (*Nature*, **226**, 705; 1970) has well and truly upset the apple cart.

In brief, Dube and Rudland have shown that after infection with T4 phage the ribosomes of *E. coli* recognize the initiation signals of T4 mRNAs much more efficiently than they recognize start signals in *E. coli* or RNA phage messengers. Moreover, when initiation factors that can be washed off ribosomes from infected cells are added to washed ribosomes of uninfected cells, these ribosomes then behave as if they came from infected cells. In other words, after infection with T4 it seems that a new set of factors, specified by the phage, are made. These then displace the host cell factors and cause the ribosomes to recognize preferentially the start signals of T4 messengers, while restricting their capacity to recognize *E. coli* start signals. The new initiation factors subvert the host cell's synthetic machinery towards making phage protein. Rudland and Dube have gone some way towards isolating the new factors, and the next step is to characterize them.

With Steitz, Rudland and Dube have followed up their finding that T4 infection dramatically reduces but does not completely abolish the ability of *E. coli* ribosomes to bind to R17 phage RNA. Using factors and ribosomes prepared by Rudland and Dube in the system for isolating the R17 start signals, Steitz and her colleagues find that the factors from cells infected with T4 selectively change the capacity of *E. coli* ribosomes to bind to the three different R17 signals. Ribosomes with initiation factors from uninfected cells bind much more efficiently to the start sequence of the R17 coat protein than to the start signal of the maturation gene. By contrast, ribosomes with initiation factors from infected cells discriminate against the start signals of the coat gene; they bind with equal efficiency to both coat and maturation genes. The conclusion from these experiments must be that the initiation factors, not the ribosomes, determine the efficiency with which different gene initiation signals are recognized.

In *Nature* last week, however, Lodish reported equally clear cut experiments leading to precisely the opposite conclusion. He has measured the synthesis of coat, maturation and RNA replicase proteins of the RNA phage f2, a near relation of R17, in cell free systems primed with f2 RNA. In a cell free system from *E. coli*, the host of f2, all three proteins are made, but the amount of coat protein produced greatly exceeds the amount of maturation protein. A cell free system from *Bacillus stearothermophilus*, however, makes only maturation protein. Using mixed cell free systems with various components from *E. coli* and *B. stearothermophilus*, he shows convincingly that the source of the 30S ribosomal subunit uniquely determines whether three or one phage proteins are made. For example, a system containing *B. stearothermophilus* 30S subunits, *E. coli* initiation factors and 50S subunits makes only maturation protein. Conversely, if the 30S subunits come from *E. coli* all three proteins are made. Lodish also mentions that the ribosomes of *B. megatherium*, like those of *B. stearothermophilus*, will only translate the maturation protein gene.

Lodish's results point to the 30S ribosome as the determinant of the specificity of translation, while Dube and Rudland and Steitz's experiments indicate that the initiation factors play a part in messenger selection. But are *E. coli* and *B. stearothermophilus* infected with T4 phage really comparable? The messenger selection process involving initiation factors may be a specific feature of phage infection, a mechanism for sequestering the host's synthetic machinery for the production of phage protein just as sigma factors induced by T4 phage subvert *E. coli* RNA polymerase to making T4 phage RNA. On the other hand, it may be an example of a universal process for transiently programming ribosomes to recognize particular initiation signals.

In terms of cellular economy this is an attractive suggestion, but if it proves to be the case how can Lodish's experiments be explained? It would be particularly valuable to know how many R17 start signals can be recovered in Steitz's system using washed *E. coli* ribosomes and *B. stearothermophilus* factors. Lodish's experiments indicate that all three signals should be obtained, whereas if the initiation factors select start signals only that of the maturation protein should be found. Until further experiments have been done, you can pay your money and take your choice, or rather enjoy your prejudice.

PROTEINS

Through the Polarimeter

from our Molecular Biology Correspondent

IMPROVEMENTS in instrumentation during the past year or two have enormously increased the scope of optical rotatory dispersion (ORD) and circular dichroism (CD) measurements in protein chemistry. Aficionados of the technique will find several papers to engage their attention in the current literature.

In globular proteins, it is now a commonplace that Cotton effects, often of considerable magnitude, occur in the near-ultraviolet absorption bands of tyrosine and tryptophan. A systematic analysis of these effects has been attempted by Horwitz, Strickland and Billups (*J. Amer. Chem. Soc.*, **92**, 2119; 1970), who have followed up their previous papers on the optical activity of tryptophan and phenylalanine derivatives with a study of tyrosine, in relation particularly to ribonuclease, which shows a substantial Cotton effect associated with the absorption band of its six tyrosine residues. A series of simple derivatives studied in glassy solvents at liquid nitrogen temperature show fine-structure in both absorption and CD, which makes it possible to analyse the vibrational composition of the bands. The phenolic chromophore contains two transitions in the near ultraviolet, and Horwitz *et al.* have been able to make out the two corresponding vibrational progressions, one strong and one weak. Their positions are very solvent-sensitive, and it is therefore to be expected that in ribonuclease, which has three buried and three exposed tyrosine residues, there will be progressions arising from both classes (if both show enhanced optical activity). At low temperature, fine-structure appears, and with the aid of a curve-resolver, and only a modicum of imagination, bands representing the first members of three progressions can be discerned, two from internal, and one from the external, solvent-perturbed, residues. A large disulphide contribution extending to long wavelengths is also in evidence. Thus it is in principle possible to distinguish not only tyrosine from tryptophan components, but also internal from external ones, and the possibility arises of observing events around individual aromatic residues in globular proteins generally.

The remaining examples are concerned with some applications of ORD and CD in following changes in structure. Conjugated proteins, such as those containing haem, show complex systems of Cotton effects in the absorption bands of the prosthetic groups. Drucker, Campbell and Woody (*Biochemistry*, **9**, 1519; 1970) describe the Cotton effects of the cytochrome c_3 of three related sulphate-reducing bacteria. In spite of the low molecular weight of 14,000, these proteins are reported to carry three haem groups each. They have very large Cotton effects, particularly in the intense Soret absorption band. The results show that in spite of the considerable differences in amino-acid composition the three proteins are effectively identical in terms of the haem environment. On acid denaturation, there is a sharp diminution in the Cotton effects, and this can be used to follow the denaturation with great precision. Treating the process as a proton binding equilibrium, binding plots show that six protons are taken up on unfolding. Three of these are surmised to involve the haem-linked imidazole groups.

A number of workers have been much exercised to interpret the CD of intact membranes. This has, not surprisingly, proved difficult, because of the macroscopic nature of the material. Urry and Krivacic (*Proc. US Nat. Acad. Sci.*, **65**, 845; 1970) have analysed the effects of differential scattering of left and right-circularly polarized light—a phenomenon long known in optics—and have shown that it can in principle account for much of the distorted shape of the peptide Cotton effects observed in these systems. In spite of this kind of complication, however, it is occasionally possible to extract useful information from the CD of membranes. Glaser *et al.* (*ibid.*, 721) have, for example, found that the peptide Cotton effects, and therefore the protein conformation, do not change on treatment with phospholipase, which leads to the release of some 70 per cent of the total phospholipid. Moreover, the digestion is accompanied by the emergence of a series of resonances in the proton magnetic resonance

(PMR) spectrum, not evident in the intact membrane, and corresponding to the spectrum of extracted lipids in solution. By contrast, when membranes are heated, the breakdown of the protein structure can be followed by the change in CD, and this is associated with the appearance of the PMR spectrum of unfolded protein chains, but not of the methylene resonances of the fatty acid lipid chains, which evidently remain essentially immobile. It thus seems that the disordering of the proteins and of the lipids are independent and unrelated processes. Glaser *et al.* infer that the proteins are directly associated with only the minor fraction of phospholipids that are not destroyed by phospholipase, and are distributed in self-contained packets in a lipid bilayer matrix.

POLIO VIRUS

All or Nothing

from our Cell Biology Correspondent

At first sight the RNA coliphages have much in common with polio virus and its relatives. Both the RNA phages and the RNA viruses have a single stranded RNA molecule for a genome which also doubles as a messenger RNA. Moreover, the phage RNA certainly, and the viral RNA most probably, specifies a replicase enzyme for its own replication. But there the similarities end; the way in which the phage and viral proteins are made could hardly be more different.

The phages specify three proteins, their coat, their replicase and a maturation protein. Polio virus, on the other hand, has enough genetic information to specify about ten proteins, four of which are in the capsid and a fifth is the replicase. On the face of things polio virus is far more sophisticated than the coliphages, but compared with them it makes its proteins in a curiously unregulated fashion.

Both *in vivo* and *in vitro* the coat protein gene of the RNA phages is translated more efficiently than the other two genes. Apparently the coat protein molecules act as repressors for translation of the replicase gene while the maturation protein gene is initiated with a base sequence for which *E. coli* ribosomes have a comparatively low affinity. The net result is the preferential synthesis of coat, which one imagines confers a selective advantage on the phage, which needs 180 coat molecules but only one maturation protein to encapsidate one RNA molecule.

By contrast the translation of polio virus RNA, as the work of Baltimore and his associates has shown, is a profligate affair. The results of experiments carried out during the past several years suggest that the whole genome is translated into a single polypeptide chain which is then cut up to yield the specific viral proteins. By using three amino-acid analogues, Jacobson, Asso and Baltimore (*J. Mol. Biol.*, **49**, 657; 1970) now claim to have isolated for the first time this mammoth polypeptide. It has a molecular weight in excess of 200,000 daltons and, in the uniquely cumbersome terminology polio workers have saddled themselves with, is labelled non-capsid viral protein -00 (NCVP-00). Apparently the amino-acid analogues prevent NCVP-00 from being cleaved as it usually is before its synthesis is complete; the largest nascent polypeptides recoverable from cells infected with polio virus in the absence of analogues have molecular weights of less than 130,000.

Drawing on their own earlier work and that of others, and by isolating the various cleavage products of NCVP-00 and making tryptic peptide maps to sort out their relationships, Jacobson *et al.* have proposed the following scheme for the origin of polio virus proteins. NCVP-00 is envisaged as the common precursor which, when cleaved, yields NCVP-1, NCVP-2 and NCVP-X. Only NCVP-1 provides the proteins found in the virus. It is split to yield viral proteins VP1 and 3 of the procapsid as well as VP-0. VP-0 is envisaged as the precursor of the two other viral proteins VP2 and VP-4 which are generated as the procapsid matures. NCVP-2 and NCVP-X are presumably the precursors of the viral proteins involved in RNA replication and the switching off of host metabolism.

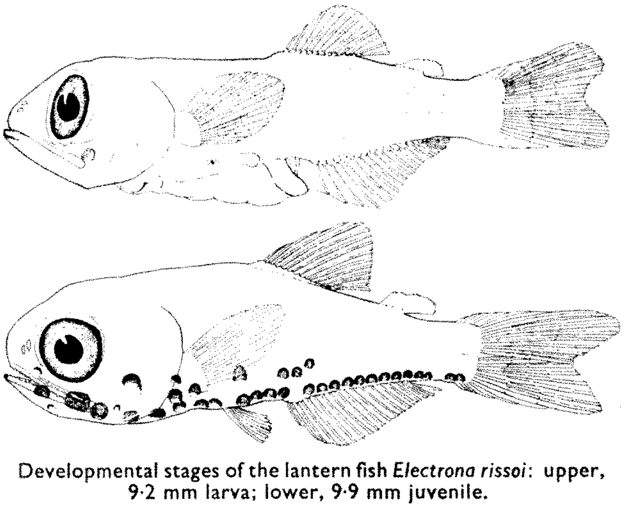
Apart from the problems of controlling the specificity of these cleavages the most surprising aspect of this process is that to make a coat protein polypeptide, polio virus apparently has to make all its other proteins. By comparison the RNA phages are models of cellular economy.

DEVELOPMENT

New Light on Lantern Fishes

from our Marine Vertebrates Correspondent

Lantern fishes, recently the subject of a valuable developmental study, are both abundant and widespread in the upper layers of the oceans, and therefore one of the primary forage foods for larger and commercially important oceanic fishes. In some cases densely shoaling species are fed on directly by tunas in the Pacific, and numerous lantern fish have been found in the food of the germon (*Thunnus alalunga*) in the Golfe du Gascogne.



Developmental stages of the lantern fish *Electrona rissoi*: upper, 9·2 mm larva; lower, 9·9 mm juvenile.

But the principal place of these myctophid fish in the feeding relationships of the ocean is at one remove, for they are preyed on by the smaller predators which are then eaten by the larger fish. They thus form a vital link in the food web of the seas. Lantern fishes are perhaps the most widely distributed family of fish in the world's oceans, represented by many species, which, in spite of some revisionary studies, are not fully understood. A recent important contribution to the better undertanding of the eastern Pacific species has been made by H. G. Moser and E. H. Ahlstrom (*Bulletin of the Los Angeles County Museum of Natural History*, Science No. 7, 1; 1970).

Moser and Ahlstrom have examined material collected during ten years of intensive and systematic surveys of the California Current Region off California and Baja California. They fully describe and illustrate the developmental stages of fourteen species of myctophid belonging to eleven genera, restricted to larvae in which the eyes are narrow (in the other major group the eyes are rounded). In spite of this restriction the work is of considerable value.

The first major contribution to the description of lantern fish larvae and young stages from an adequate series was that of Tåning, who in 1918 described several Mediterranean forms. This early lead was not followed until Pertseva-Ostroumova (*Akad. Nauk. SSSR Inst. Okeanologii Trudy*, **73**, 79; 1964) described the larvae of eighteen myctophid genera from the Pacific and Antarctic Oceans. Later she described the larvae of a further nine Antarctic lantern fishes. But Moser and Ahlstrom disagree with some of the identifications given by Pertseva-Ostroumova.

Moser and Ahlstrom's work can therefore be seen as a major advance in the identification of the larvae of this group of lantern fishes. It is now possible in this area to use these larvae as biological indicators of the water masses in which they were found, and Moser and Ahlstrom distinguish several major ecological assemblages off the Californian coast. This work will also improve knowledge of the ocean food web.

GENETICS

Chemicals and Mutations

from a Correspondent

THE Environmental Mutagen Society, founded last year as a result of the concern felt by many scientists about the potential mutagenicity of the ever increasing number of synthetic chemicals in the environment, has just held its first annual meeting. About 250 of the society's 450 members attended.

In his opening address, Dr H. Bentley Glass (State University of New York at Stony Brook) discussed many of the problems involved in the detection of the genetic effects of chemical mutagens in the human population and in the extrapolation to man of data obtained with experimental systems. He stressed the urgent need for more research to enable geneticists to evaluate the effects of such agents directly on man.

The problem of monitoring the human population for an increase in the frequency of genetic damage was also discussed by Dr J. Crow (University of Wisconsin, Madison), who pointed out that even if methods could be developed for the detection of an increase in the genetic load there might be great difficulty in determining the exact cause of the increase. The feeling that harmful genetic effects in man should be prevented by careful screening of man-made chemicals before they are released on to the market was reflected when various test systems were discussed. Several speakers considered the relationship between the mutagenicity and carcinogenicity of nitroso and other compounds.

An investigation of the cytogenetic effects of cyclohexylamine in *in vitro* studies on tissue culture of the rat-kangaroo and *in vivo* studies with rats was presented by Dr S. Green (FDA), and Dr J. Verrett (FDA) reviewed the striking teratogenic effects of cyclamates in the chick embryo.

Evidence was given for the mutagenicity of various man-made chemicals that pollute the environment, including ethylene dibromide (Dr F. J. de Serres and Dr H. V. Malling, Oak Ridge National Laboratory), methyl mercury (Dr C. Ramel, University of Stockholm), captan (Dr G. Fiscor, Western Michigan University, Kalamazoo, and Malling and de Serres), and sulphur dioxide (Drs R. Shapiro, R. E. Servis, B. I. Cohen and M. Welcher, New York University).

MINERALS

Mineral Wealth of Wales

from our Structural Geology Correspondent

THE exploitation of minerals and the economic geology of Wales were the theme of a University of Wales colloquium held on May 14 and 15 at Cardiff. It was appropriate that the meeting coincided with the announcement of new legislation affecting planning for mineral exploitation in Britain, and Mr Cyril Leigh (University College, Cardiff) pointed out that the current exploration boom in Southern Ireland could be directly related to analogous legislation in Eire.

In a stimulating contribution, Dr J. W. Baker (University College, Cardiff) defined the fundamental tectonic patterns of the Welsh Region, which he claimed had already been initiated by Late Pre-Cambrian times. He speculated on the relationship between these and deep-seated metallogenic provinces. In the context of the recent discoveries of workable mineral deposits in Eire, delegates discussed the possibility of a symmetrical tectonic pattern between Ireland and Wales, and consequently of mineral deposits yet to be discovered in the Welsh Region.

As an example of mineralization in the Caledonian Province, Dr W. J. Phillips (University College, Aberystwyth) discussed the lead and zinc mineralization in Central Wales. By the application of hydraulic fracturing in rock mechanics he showed that the mineralization process was instantaneous. The hydrothermal solution pressure built up until pre-existing tension fractures were suddenly dilated with the consequent upsurge of mineralizing solutions, producing breccias around which the lead and zinc sulphide phases were deposited.

The description of the various ore mineral associations in South Wales by representatives of the Wolfson Research Group (University College, Cardiff) ranged from the haematitic iron ores of Glamorgan (Dr R. A. Gayer), a branch of the mining industry suffering from severe competition from the massive importing of relatively cheap ore from the Commonwealth, through the lead, copper and zinc assemblages in the Carboniferous Limestones and Mesozoic strata of the Vale of Glamorgan (Dr C. M. L. Bowler and Mr G. A. Kingston) to the gold ores of Dolaucothi in Carmarthenshire. Work being carried out by Mr A. Pinches on microbiological and biochemical searching methods for the gold ores may well lead to an economic process of gold production from low grade ores and from gold which is difficult to extract by standard chemical processes.

Bulk mineral deposits also received their share of attention, and Professor J. G. C. Anderson (University College, Cardiff) showed that there are large deposits of sand and gravel beneath the coastal alluvial clays of the Severn Estuary. These largely occupy buried river channels overdeepened during the glacial period. In his contribution Dr R. G. Thurrell (Institute of Geological Sciences) explained the complex procedure required for the assessment of sand and gravel resources.

ELECTRONICS

Surface Wave Filters

A NOVEL development in integrated circuit technology is the use of acoustic surface waves to make cheap and effective frequency selective filters for television amplifiers. This latest application of the newly fashionable surface wave devices is a departure from their chief use as dispersive elements in radar systems. According to a report in the Mullard Research Laboratories (MRL) annual review, the new surface wave filter can be used instead of conventional resonant circuit filters in amplifiers operating at frequencies of a few tens of MHz. At such frequencies inductors become too big to be used as part of integrated circuits and an alternative way of providing frequency selective elements has to be found.

The new MRL filter relies on the interference between acoustic waves generated on the surface of a piezoelectric crystal to provide the necessary selectivity. It consists of a pair of transducers formed as geometrical arrays of thin gold electrodes on the surface of a piezoelectric chip; one to generate and the other to receive the waves. The geometric arrangement of the electrodes determines the way in which the waves interfere, so that by careful choice of the geometry the response of the filter can be tailor made to suit a particular amplifier circuit. Using computer optimization techniques the Mullard team has designed filters which have apparently worked well in a 37 MHz colour television receiver.

The filter is small enough to be used as part of an integrated circuit assembly, but there are still problems in the way of integrating it completely with a silicon chip. The other problem in making the new device commercially viable is to find a ceramic base which is more stable against changes in temperature.

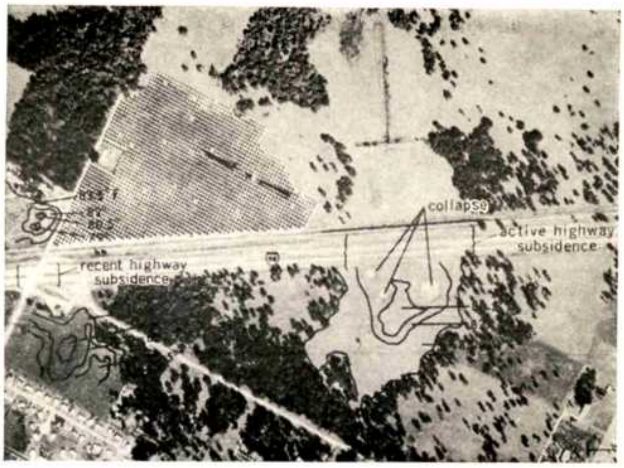
CATASTROPHES

Sources of Sinkholes

from our Geomagnetism Correspondent

NORTH AMERICA is subject to a remarkable variety of natural catastrophes—tornadoes, hurricanes, earthquakes and tsunamis, far from uncommon in one part of the country or another, are only the most devastating. Less spectacular, though equally frightening, expensive and, on occasion, fatal to those whom they afflict, are the minor geological perturbations which come under the general heading of land deformations.

"Sinkholes", or small localized regions of land collapse, are a case in point. The sudden formation of sinkholes is related to the existence of cavernous limestone, estimated to lie beneath about fifteen per cent of the forty-eight states which make up the continental United States. The most important of the areas where sinkholes are common is thus the "Great Valley" lying east of the Appalachian Mountains and extending from New York State to Alabama, Georgia and Florida, although land collapse of this type is not unknown in Kentucky, Tennessee and New Mexico.



A black-and-white print of a coloured infrared "thermal" map showing thermal contours superimposed on a photograph of sinkholes near Bartow, Florida. (Photo, US Geological Survey.)

From now on, however, sinkhole disasters should become less frequent because of progress made in the detection of potential sinkhole positions. The Bartow–Lakeside–Winter Haven region of Florida, an area particularly prone to sinkhole collapse, has been investigated by scientists from the US Geological Survey and the University of Michigan using airborne remote sensing devices. They found that collapsed regions and areas highly susceptible to collapse have anomalous thermal and moisture characteristics which are easily revealed by infrared detection devices. It is hoped that no further development will take place within clear disaster areas although, perhaps understandably, urban planners will have mixed feelings about the introduction of yet another restriction on their activities.

SIGNALS

Improving Radio Telephones

from a Correspondent

TRANSMISSION and reception of radio telephony at h.f. and v.h.f. provided the principal theme of the conference held by the Institution of Electrical Engineers in London from May 19 to 21. The topic for discussion was signal processing methods for radio telemetry, and there was no doubt that the most recent significant h.f. advance has been the Lincompex (linked compressor expander) system. This achieves a considerable saving in power in overcoming distortions due to multipath fading and noise. The principle of Lincompex is to bring all speech syllables to the same maximum amplitude (compression), so that all are transmitted at maximum power. A narrow band control signal is transmitted simultaneously, defining the degree of compression. At the receiver, the control signal is used to restore the received speech signal to its original form (expansion). Technical details and operational aspects of Lincompex were described in three contributions by a team from Marconi, GEC, STC, the Post

Office and Bell Telephone Laboratories. The first Lincompex system was introduced in 1967, and since then about 500 sets have been installed on point-to-point circuits.

Although radio telephony may suggest analogue techniques, about half the presentations dealt with digital signal transmission. Many aspects of signal processing are achieved more easily when the signal is digital, and analogue-to-digital conversion enables speech to be represented in this form. Digital transmission also brings the advantages of regeneration, tolerance to crosstalk and interference, and the opportunity for high security encoding.

Several contributors discussed the conversion of speech to digital form, including Mr R. M. Wilkinson (Signals Research and Development Establishment, Christchurch), who gave a subjective assessment of the various methods (all of which inherently give rise to distortion). He concluded, for example, that a six digit pulse code modulation system, compressed and then expanded, requiring a transmission rate of 40·6 kbits/s, gives a received speech quality which can be understood with almost complete relaxation in ideal transmission conditions. On the other hand, vocoder processing gives speech which is understood with slight effort, but the transmission rate is reduced to 2·4 kbits/s. Vocoder processing is important because 2·4 kbits/s can be transmitted in a single sideband channel normally used for conventional analogue speech transmission, although this is not achieved at h.f. without advanced signal processing. Four contributions dealt with adaptive methods of reception of such high rate data streams. This technique involves cascading the channel with a time varying network at the receiver, which serves to minimize dynamically the effects of channel distortion. But the usefulness of adaptive systems on h.f. channels was doubted by W. Struszynski (Marconi), who compared their performance with more simply realized systems.

Apart from the many problems of h.f. and v.h.f. radio telephony in analogue and digital form, the solutions of similar problems at higher frequencies were presented. G. L. Grisdale (Marconi) proposed a new application of swept frequency techniques for speech and data transmission from air to ground, via satellite, and R. C. Fitting (Motorola) presented design information and gave test results for a 2·8 Mbits/s tropospheric scatter data link.

ROCK MAGNETISM

Effects of Oxidation

from a Correspondent

THERE were some differences of opinion about marine magnetic anomalies and oxidized basalts at the annual meeting of the American Geophysical Union in Washington from April 20 to 24. The origin of the Mason–Raff magnetic lineations on the ocean floor has been explained by the Vine–Matthews hypothesis, which appeals to the normal and reversely polarized lava flows on the ocean floor. Direct confirmation of the hypothesis must wait until continuous coring can be extended beyond the sediments to the basalt flows. In anticipation of this, however, the basalts dredged from the mid-Atlantic ridge and away from it have been studied by Drs S. E. Haggerty (Carnegie Institution, Washington) and E. Irving (Observatories Branch, Ottawa) for an explanation of a certain peculiarity of the marine magnetic lineations.

The amplitude of the anomaly at the ridge is usually twice as large as the anomalies 5–10 km away (laterally). Farther from the ridge, the amplitude continues to decrease, but more slowly. Haggerty and Irving explained the initial decrease in amplitude on the basis of magnetic and petrological properties of basalts dredged from the Median Valley at the Mid-Atlantic Ridge (45° N) and those collected about 5 km away. They found that the opaque titanomagnetites in the Median Valley are unoxidized and carry an unusually large (10^{-1} gauss) natural remanent magnetization (NRM). Away from the ridge, however, titanomagnetites were oxidized ("maghaemitized") with a much lower (5×10^{-3} gauss) NRM. Haggerty explained the lack of oxidation in the Median Valley as the influence of the trapped sulphur volatiles: large concentrations of pyrite, pyrrhotite and chalcopyrite were found. Oxidation presumably starts as soon as the basalts are carried away from the ridge by sea-floor spreading. The NRM is partially destroyed and a chemical remanent magnetization (CRM) results which is much weaker than the initial NRM.

These results from dredged basalts were contradicted by laboratory oxidation studies performed on oceanic basalts by Drs M. Marshall and A. Cox (Stanford University). To be sure, they also found that the NRM can be destroyed by heating (to temperatures between 200° C and 300° C in air). But the new CRM that resulted from the laboratory oxidation was stable and strong and, for some specimens, several times larger than the original NRM.

There was doubt at the meeting as to whether the chemical composition and the crystallographic structure of the products of laboratory oxidation were the same as those relating to the maghaemites found by Haggerty in the naturally oxidized samples.

Professor K. Creer and his co-workers (University of Newcastle, England) presented magnetic data obtained from maghaemites or oxidized titanomagnetites, which were formed by heating to 200° C in air, after wet-grinding with water in a ball mill. Creer claimed that the preliminary wet-grinding process allows a more accurate simulation of the magnetic minerals found in natural basalts. But Creer was followed by Drs S. K. Banerjee and P. E. D. Morgan (Franklin Institute, Philadelphia), who reviewed all attempts at laboratory simulation of the magnetic minerals of natural basalts and pointed out their deficiencies. They pointed out that Mössbauer data obtained from Creer's wet-ground titanomagnetites show that even such materials undergo spurious changes in magnetic properties when oxidized, because the wet-grinding process produces ultrafine, superparamagnetic particles which later change their magnetic properties, not only because of oxidation, but also due to sintering and grain growth. It seemed to be crucial that in order to simulate natural oxidation, the starting laboratory samples must contain cation vacancies but no nuclei of rhombohedral haemo-ilmenite impurities. The presence of such impurities even in microscopic amounts (for example, stacking faults in the cubic titanomagnetites) leads to a kinetically preferred magnetite–ilmenite intergrowth, rather than the cation-deficient maghaemite found in nature.

Metabolic Adaptation in the Brain

by
HENRY McILWAIN
Department of Biochemistry,
Institute of Psychiatry,
De Crespigny Park,
London SE5

Enzyme adaptation in the brain involving substrates, hormones and neurotransmitters may participate in behavioural adaptation, consolidation in learning and central aspects of drug tolerance. This article is based on lectures given in October 1969 to the Oxford University Biochemical Society and to the Neurochemical Group of the Biochemical Society.

The brain has become the major means by which higher animals and especially man adjust to changes in their environment. Enzymatic and metabolic adaptation play large parts in the adjustment of most organs of the body to changed circumstances, and this article has been prompted by new data which demonstrate that metabolic adaptation occurs in the brain and is of much importance in cerebral functioning.

Cerebral Adaptation to Specified Substrates

The principal oxidizable substrate of the adult mammalian brain is subject to alteration by enzyme induction[1]. Limitation of glucose supply to the brain usually results in loss of consciousness; lowering the concentration of blood glucose by means of insulin causes coma, and other administered substrates do not then replace glucose in restoring full cerebral functioning[2,3]. But in starvation, when the carbohydrate reserves of the body are lost gradually and β-hydroxybutyrate becomes the principal oxidizable substrate in the bloodstream, the brain also gains the ability to utilize it[4]. This was found to occur after some weeks in man or after 2 days in the rat[1]. By this time the β-hydroxybutyrate dehydrogenase activity of the mitochondria in the rat brain had increased nine-fold. In man a cerebral respiratory quotient much below unity showed that compounds derived from fat were serving as major cerebral substrates.

Relatively normal consciousness was maintained during some weeks of starvation in man, although carbohydrate reserves would have been exhausted in 2 to 3 days even if the brain was the only organ which utilized carbohydrate[4]. Thus the brain not only oxidizes β-hydroxybutyrate but also derives essential energy requirements by doing so. The metabolic basis for this has been shown in the rat by demonstrating synthesis of adenosine triphosphate with β-hydroxybutyrate as the only oxidizable substrate in cerebral preparations from adapted animals[5].

This cerebral metabolic adjustment to changed bodily circumstances was a characteristic of β-hydroxybutyrate dehydrogenase rather than other enzymes[5]. The dehydrogenase was assayed when maximally activated, and so presumably this particular cerebral constituent had increased nine-fold while maintaining cerebral functioning during starvation. The mechanism is not at present specified, but there are resemblances to the way in which iron stimulates the synthesis of ferritin in the liver, and haematin stimulates the synthesis of the protein moiety of haemoglobin in reticulocytes or avian erythrocytes.

As for other enzymes of the brain, an increase in the activities of L-glutamate dehydrogenase[6] and tyrosine transaminase[7] was found when their respective substrates were added. Other examples of an increase in cerebral enzymes have depended on hormonal inducing agents—glycerol phosphate dehydrogenase[8] and Na, K-ATPase[9] stimulated by cortisol or cortisone, and lactate dehydrogenase[10] and adenyl cyclase[11] by adrenaline or noradrenaline, as discussed later. Cerebral examples thus seem to be available for two principal categories of enzyme induction[12]: one initiated by substrate or coenzyme and found in other tissues not to require synthesis of ribonucleic acid (RNA), and the other initiated by a hormone-like agent and typically needing additional RNA synthesis. The inducing agent, again, may affect either the synthesis or the breakdown of the component, RNA or protein, on which it acts; various principles may well be involved in the very different cerebral systems from which these examples are drawn (Fig. 1).

The ability to augment certain enzyme systems according to need has been regarded as an understandable part of the economy of simple organisms since the characterization of adaptive enzymes in bacteria[13]. The brain, also, can presumably be more compact and specific in function by not always possessing maximal enzyme activities for all the metabolic potentialities provided genetically. This implies regulatory processes conditioning genetic expression which in other organs can proceed by several mechanisms[12,14], some of which are considered later.

Adaptive Changes in Functioning

Augmentation of β-hydroxybutyrate dehydrogenase enables cerebral functioning to continue relatively unchanged when material supplies alter. Are comparable processes of metabolic induction involved when material supplies to the brain remain unchanged but cerebral responses alter? If so, evidence should be available for increased metabolic turnover in specified routes, or for increased synthesis of protein or of other necessary components. Table 1 summarizes four examples of such evidence.

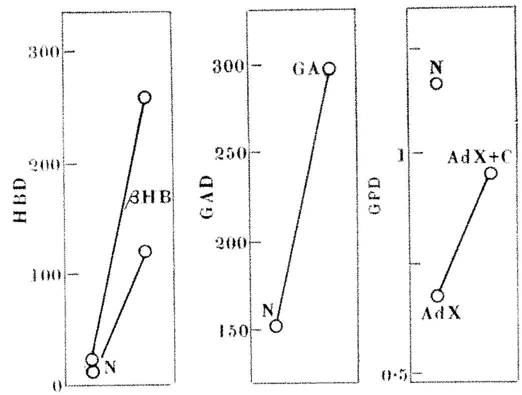


Fig. 1. Augmentation of enzymes in the brain of adult mammals by administration of a substrate or hormone. HBD, β-Hydroxybutyrate dehydrogenase (μmoles/g/h) on feeding rats diets which augmented circulating β-hydroxybutyric acid[1]; these animals (βHB) are compared with normal controls (N). The upper points give values for the enzyme activated with lecithin. GAD, Glutamic acid dehydrogenase (μmoles/g/h) of mice[6] with increased cerebral glutamic acid (GA) compared with normal controls (N). GPD, Glycerolphosphate dehydrogenase (μmoles/g/h) of rats[8]: animals were normal (N), adrenalectomized (AdX) and adrenalectomized and receiving cortisone (AdX + C).

Melatonin, an indole derivative which is formed exclusively in a particular part of the brain, the pineal, is involved in the first of these instances (second row of Table 1; Fig. 2). Melatonin controls diurnal and seasonal adjustments of activity in many species[15–17]. It has been found to modify the psychomotor activity (wheel-running)[18] of rats, and could cause an eight-fold change in the gonadal weight of hamsters[17]. The melatonin content of the pineals of rats varied seven-fold during the day according to the illumination incident on the animals[16]. The changes were found to be mediated by neural connexions which came from the eye and which terminated at the pineal and there liberated noradrenaline, which augmented hydroxyindole-O-methyltransferase, the final and rate-limiting enzyme synthesizing melatonin[19]. Two lines of evidence indicated this to be an enzyme induction. First, the enzyme was assayed in maximally activated conditions and had presumably itself increased several-fold in quantity and, second, the augmentation involved protein synthesis, being inhibited *in vivo* by puromycin[20] and in isolated pineal glands by cycloheximide[19].

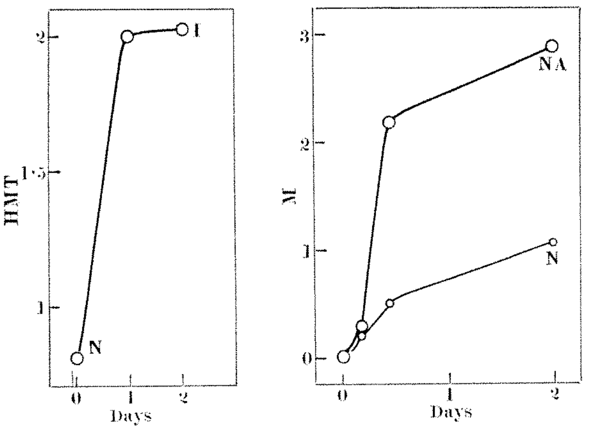

Fig. 2. Formation of melatonin (M; percentage yield from tryptophan) by hydroxyindole O-methyltransferase (HMT; pmoles/h) of the pineal gland of adult rats as a result of diminished illumination[20] (I), or of the addition of noradrenaline (NA) to cultured pineals[19]. N, Normal illumination or no addition.

Table 1. CHARACTERIZATION OF CEREBRAL ADAPTIVE PROCESSES

Process	Metabolic data
Maintenance of cerebral functioning in starvation and ketosis	Adaptive increase in mitochondrial β-hydroxybutyrate dehydrogenase
Adjustment of daily and seasonal rhythms by illumination: maintenance of certain gonadal functions	By pineal melatonin, the hydroxyindole-O-methyl synthetase for its formation being induced by noradrenaline
Development of tolerance to morphine on continued administration	Associated with increased incorporation of ^{32}P into phospholipids; inhibited by puromycin or cycloheximide
Sustained increase in cortical cell firing by surface-positive polarization	When established, persists after cooling the cortex to 20° C. Establishment blocked by cycloheximide or neomycin
Retention of certain induced behavioural changes:	
(*a*) Short-term memory	(*a*) Insensitive to inhibitors of RNA and protein synthesis
(*b*) Development of long term memory	(*b*) Blocked by acetoxycycloheximide and puromycin; actinomycin *D* depresses and could act by diminished protein synthesis

Metabolic data are chiefly from the rat; for references and further details, see text.

Phenomena of drug addiction and drug dependence have many characteristics which suggest that the changed behaviour of dependent animals is metabolically based. Development of tolerance to morphine in rats was found to be accompanied by changed oxidative and phospholipid metabolism in the brain itself (Table 1)[21,22]. When induced in acute experiments by intracarotid infusion of morphine, the development of tolerance was inhibited[23] by puromycin, cycloheximide or actinomycin *D*: enzyme induction thus seems to be involved in producing the state of tolerance. The cerebral metabolites most affected in the development of tolerance were phosphatidylserine and triphosphoinositide. The connexion between these and metabolic changes and the development of tolerance was demonstrated in the whole animal by several techniques. For example, there was slow reversion towards normal metabolism when addicting drugs were withdrawn[22], and some cross-tolerance was demonstrated at metabolic level between morphine, meperidine and methadone[21]. Mixtures of amphetamines and barbiturates, when causing long-term behavioural changes in experimental animals[24,25], were also concluded to act by blocking synthetic processes in the brain.

An imposed change in cerebral activity at electrophysiological level has shown properties which suggest it to be metabolically based (fourth row of Table 1)[27]. The firing of cortical cells in rats was accelerated four-fold by making the cortical surface electrically positive in relation to deeper structures[26]. After it had been imposed for about 10 min this change in rate of firing usually persisted for some hours after the positive polarization had been discontinued, and indeed it survived the cessation of electrical activity in the brain when this was brought about by lowering the animal's temperature. The immediate effect of the positive polarization in increasing cell-firing proved resistant to various treatments including the administration of inhibitors of protein synthesis, for example cycloheximide. Very significantly, however, these compounds prevented the continuance of the high rates of firing, which now reverted to their lower values when polarization was interrupted[27]. Persistence of the imposed change thus required new or augmented protein synthesis; the experiments did not indicate the nature of the protein so functioning, although an association with neurotransmitting agents would explain the observed action on cell-firing.

An interesting parallel is the state of knowledge about changes in cerebral activity induced by behavioural manipulations (fifth row of Table 1). In some of the best-devised and appraised cases[28–30] the immediate performances of animals in test conditions were unaffected by administrations of puromycin or of acetoxycycloheximide which inhibited protein synthesis in the brain by some 90 per cent. Performance on subsequent days was, however, below that of normal animals which had not received the compounds but had learned in the test conditions. The development of this difference was dependent on time; adopting the description of long term and short term memory to account for these performances, the administered compounds at first had no effect but blocked the process of consolidation which converted short to long term memory[30,31]. The incorporation of labelled precursors also suggested that cerebral protein and RNA fractions were altered when an animal's behaviour was caused to change in circumstances which as far as possible separated the behavioural performance from other bodily changes; in these conditions incorporation to cerebral DNA was not observed to alter[30].

Neurohumoral Agents in Metabolic Adaptation

When considering mechanisms, the first thing to note is that I have given six examples of alteration in the metabolic make-up of the brain when it is exposed to secreted humoral agents. Enzyme induction is indeed a major route of hormonal action generally. It can be involved when the brain is the target organ for compounds synthesized elsewhere: cortisol and triiodothyronine[32,33] have such actions; and it can be involved when the brain is the source of a hormone acting extracerebrally as when growth hormone from the pituitary acts on the liver[34], increasing there the incorporation of ^{14}C-leucine or ^{3}H-orotic acid. Induction of hydroxyindole-O-methyltransferase gave a purely intracerebral example of liberation of a neurohumoural agent and its induction of a critical enzyme. Do cognate phenomena occur more generally in the brain in relation to putative neurotransmitters? The investigations summarized in Table 2 suggest that this is often the case.

Table 2. RESPONSES OF ISOLATED PREPARATIONS FROM THE BRAIN

Agent applied	Cerebral system	Response
Electrical stimulation	Isolated tissues	Neural transmission[35]; cation movement[2,35] Release of acetylcholine[36], noradrenaline[37], serotonin[37], γ-aminobutyrate[38] Increased cyclic AMP[40]
Acetylcholine	Synaptosomes	Incorporation to RNA[57] and phospholipid[58] increased
Noradrenaline	Tissues, surviving or cultured	Adenyl cyclase increased[41]; lactate dehydrogenase induced[10]
Serotonin	Tissues, surviving	Cyclic AMP increased[40,59]
Histamine	Tissues, surviving	Cyclic AMP and adenyl cyclase increased[40,59]
Cyclic 3′5′-AMP	Cerebral dispersion or microsomal preparation	Phosphorylase kinase activated[41]; protein kinase increased[42,43]; incorporation to peptides increased[44]

When isolated cerebral tissues were used so that both the electrical stimuli and the humoral agents applied to them were controlled, excitation produced many responses in neural conduction, transmission, cation exchange and substrate utilization[2,35]. Further, the stimuli in various preparations released acetylcholine[36], noradrenaline, serotonin[37] and γ-aminobutyrate[38]. Often these compounds are regarded chiefly as agents for inhibiting or excitating postsynaptic cells, but Table 2 and the following data suggest that several if not all can be regarded also as agents of metabolic induction.

One route by which the induction may occur involves cyclic adenosine-3′5′-phosphate (cyclic AMP). Compared with other tissues, those from the brain have the greatest capacity for the formation[39] and breakdown[41] of cyclic AMP and their content of this compound can increase forty-fold when they are exposed to electrical stimulation and neurohumoral agents[40]. In many organs, cyclic AMP is intermediary in specified categories of hormonal action[39,41] and in cerebral tissues themselves, noradrenaline, serotonin and histamine each increase cyclic AMP[40,41]. Moreover, electrical stimulation alone also brings about this effect, concomitantly with the release of neurotransmitters[40]. Activation of phosphorylase kinase in the brain is brought about by cyclic AMP[41]; in this way catecholamines modify cerebral phosphorylase itself and so glycogen. Further examples of increase in cerebral protein kinases by cyclic AMP have been reported[42,43], and also a case of cyclic AMP increasing peptide formation in cerebral preparations[44].

Persistence and Sites of Metabolic Adaptation

The incorporation of labelled precursors into RNA and protein fractions from the brain shows them to have half-lives of a few hours or a few days[45,46]; this is comparable with the persistence of several of the adaptive changes of Table 1. There are clearly advantages in changes which persist for such periods: they allow concentrations of enzyme to follow a diurnal cycle, or to adjust to daily fluctuations in the sensory impressions or the foodstuffs which an animal encounters. Other alterations impressed on the brain last longer: some learned patterns of animal activity[24,28-31] and items remembered may persist for a lifetime. Commentators have invoked special reactions (for example, at the level of DNA[47]) to explain such phenomena; but several of the agents already involved in inducing metabolic changes which persist for a few days will, in other circumstances, produce much more enduring alterations in cerebral structure or enzyme concentration. The absence or presence of thyroxine between 10 and 15 days after birth caused differential and persistent changes in rat cerebral succinate dehydrogenase[48], which were not restored to normal by subsequent administration of thyroxine; the effect was selective, for four other enzymes did not undergo comparable changes. Neonatal deprivation of thyroxine also diminished glutamic acid decarboxylase and transaminase, and the sodium-potassium-activated adenosine triphosphatase of the rat cerebral cortex[49,50]. Again, the induced enzyme differences persisted even when thyroid hormones were given after 15 days. Cortisol accelerated myelination in rats[51] when given shortly after birth, and continued administration was not needed for maintenance of the induced myelin.

These examples are akin to morphogenetic induction, operating during relatively short periods of development, and three comments are relevant. First, as Wigglesworth has said, hormones merge imperceptibly into the chemical factors responsible for local differentiation in determination[52]. Second, much differentiation during development is irreversible; a hormone can at a suitable stage act as a genetic switch in deciding a route of development; even the availability of an amino-acid at a critical time can alter permanently the expression of genetic potential[52,53] in a given organism. Third, neural control over innervated organs can be complex: when amphibian limbs regenerate, outgrowth is first inhibited when neural connexions are made, and later selectively accelerated[54]. The corresponding situation in the brain would be for neural elements to mutually inhibit growth or differentiation in general, but to induce development selectively in relation to functioning. Thus the release of a neurohumoral agent may cause structural development of some permanence, as well as enzyme induction. Indeed, enzyme induction in such cases may form part of the resumption of a specifically delayed maturation.

It is important to specify the site at which a neurohumoral agent is pictured to cause enzyme induction or more permanent developmental change. The adaptation to utilize β-hydroxybutyrate is localized in mitochondria, but most of the mitochondria of the brain are likely to be equally exposed to β-hydroxybutyrate, and indeed a large proportion of cerebral mitochondria, independently of their cellular situation, must increase their β-hydroxybutyrate dehydrogenase activity to explain available data[1,4]. By contrast, as a neurotransmitting agent noradrenaline is active at highly localized sites, and perhaps the site of action of such agents in enzyme induction is similarly localized. The following cases of metabolic induction have indeed been found to be postsynaptic: hydroxyindole-O-methyltransferase in the pineal[16]; phospholipid metabolism on stimulating sympathetic ganglia[55] and protein and ribonucleic acid metabolism induced by neural excitation in the diaphragm[56]. It is further logical that the inducing function of a neurohumour should be exerted postsynaptically because in some cases the neurohumour is considered to be synthesized in the cytoplasm of the presynaptic terminals and subsequently taken up into vesicles; thus if induction occurred presynaptically it could have done so independently of excitation. That it does so in association with excitation is demonstrated by several examples in Tables 1 and 2. The persistence of many patterns of cell-firing suggests that the converse does not hold: not all excitation is associated with adaptive change. The responsiveness of postsynaptic cells in this respect changes during development and with hormonal conditions in the animal as a whole. Acetylcholine, which does not increase cyclic AMP as does noradrenaline[59], lacks this means of metabolic adaptation.

Further significance can now be seen in those structural and enzymatic arrangements at synaptic junctions which are known to localize the action of neurotransmitting agents. Presynaptic encapsulation of the agents in vesicles, oriented intercellular material at the synapse and enzymes frequently found extracellularly which inactivate the agent have been regarded as necessary to ensure localized changes in membrane potential or cell-firing when the agent is liberated. Equally, they can contribute to localizing an enzyme-inducing effect to a limited postsynaptic site. In the pineal, sensory input altered the production of melatonin by summation of qualitatively similar actions at numerous adrenergic terminals. In other parts of the brain, individual neural connexions are less uniform in site and function and the localization of the metabolic changes induced can be correspondingly specific. Indeed, enzyme induction so conditioned can be understood to play a part in the initial growth of the brain, by favouring particular synaptic connexions in a manner related to sensory input.

Adaptation and Metabolic Turnover

Knowledge of enzyme adaptation in the brain was sparse until quite recently. Two examples were quoted in 1966[2] but little could be said about mechanism. In 1968[28] Kandel and Spencer, describing phenomena of facilitation and plasticity in neural systems, commented that "nothing is known about enzyme induction in nerve cells". Adaptation of unspecified but possibly metabolic mechanisms is frequently encountered in studies of the brain. Concepts of adaptation and habituation feature in psychological interpretations of cerebral functioning, and an "adaptation-level theory" has been propounded[60] in systematizing experimental findings in behavioural studies. That the brain is capable of a multiplicity of enzymatically based adaptations is as significant as that it contains a multiplicity of cellular interconnexions. Indeed, the two properties are related, for metabolic adaptability makes for an economy of material and greater density of packing. It requires, however, a state of flux of the metabolic machinery itself. This is vividly seen in the high rates of protein turnover characteristically found in cerebral systems.

In summary, the enzyme make-up of the brain can change (i) in maintaining normal cerebral activities in varied conditions and (ii) when cerebral functioning alters in response to altered sensory input. These metabolic adaptations are necessarily persistent, the half lives of the categories of components involved being some hours or weeks, and in specific circumstances the induced changes can endure longer still. Some of the cerebral metabolic adaptations I have described are mediated by materials from the bloodstream and others by the neurohumoral agents which are produced intracerebrally and stored, liberated and act at synaptic structures. These latter agents can therefore cause metablic adaptation which is localized, in time and cellular site, in relation to cell-firing. They thus contribute to the persistence in the brain of a spatial pattern of metabolic change related to sensory input or to endogenous cerebral activity.

An infectious C-type feline sarcoma virus (FSV), isolated from a naturally occurring fibrosarcoma of a domestic house cat, produces fibrosarcomas in kittens and puppies and induces cell transformation in feline embryo fibroblasts. Prenatal inoculation of cat and dog foetuses is particularly effective in tumour transmission. Postnatal dogs bearing FSV induced fibrosarcomas provide antisera suitable for detecting the feline C-type RNA tumour virus antigens in the complement fixation test.

MALIGNANT lymphoma in domestic cats, a relatively common feline disorder[1], is caused by a C-type RNA tumour virus[2–4]. It has been found that a feline fibrosarcoma, also caused by a C-type virus, is transmissible to kittens and puppies[5], and that the feline and murine C-type viruses share an internal soluble group specific antigen component[6]. Using rabbit antisera to ether treated feline leukaemia virus and immunogel diffusion, the presence of a group specific antigen in tissues from cats with spontaneous lymphoma was demonstrated[7]. We report here the transmission to cats and dogs of another naturally occurring feline fibrosarcoma, also associated with C-type particles, and the production in sarcoma bearing dogs of complement fixing antibodies suitable for detecting the feline C-type virus antigens.

Cat to Cat Tumour Transmission

The donor tumour was a recurrent subcutaneous fibrosarcoma obtained in March 1969 from the left flank of a five and a half year old male Siamese cat. The initial tumour was removed in November 1968, but it recurred and was irradiated with 1,000 rad in January 1969. The recurrent tumour, consisting of eight to ten firm 1·0 cm nodules located subcutaneously along the operative site, was used for electron microscopy, tissue culture and transmission studies.

The donor tumour was minced and diluted with tissue culture growth medium containing 10 per cent dimethyl sulphoxide and frozen at −70° C. After eight days storage, the tissue suspension was thawed rapidly in a 30° C water bath, centrifuged lightly (1,000 r.p.m. for 10 min) and resuspended in tissue culture growth medium to make a 10 per cent (w/v) tissue suspension. At laparotomy 0·5 ml. of this suspension was inoculated through the uterine wall into the shoulder region of six viable foetuses of a mixed breed cat at approximately 45–50 days gestation. Three apparently normal kittens were born 22 days after surgery; the other three foetuses were apparently resorbed *in utero*. Two of the three kittens developed large tumours in the shoulder region, first noticed when one was 45 and the other 71 days old (67 and 93 days following inoculation, respectively). These kitten tumours have been transmitted for three generations in 4–60 day old kittens using tumour homogenates similar to those described in the first passage (Table 1). Fibrosarcomas developed in fourteen of sixteen kittens after a latent period of 20–77 days. The longer latent periods usually occurred in the older kittens. The mother cat, from which foetuses had been inoculated with the donor tumour, was killed 100 days later; at necropsy several fibrosarcomatous nodules were found in the meso-ovarian ligament and in the uterine wall.

Cell-free virus concentrates were prepared from kitten tumours by a modification of the Moloney procedure[8,9]. (The final clarification step—low speed centrifugation—was omitted from the modified procedure.) Successful

Table 1. TRANSMISSION OF FELINE FIBROSARCOMA WITH TUMOUR HOMOGENATE

	Transplant generation								
	I	I	I	II	II	II	II	III	III
Cat to cat transmission									
Age at inoculation	*In utero*	Adult		2 weeks–2 months				4 days	
Number tumours/number inoculated	2/3	1/1		9/11				5/5	
Tumour latent period (days) measured from time of inoculation	67–93	100		34–77				20	
Cat to dog transmission*									
Age at inoculation	*In utero*								
Number tumours/number inoculated	6/6								
Tumour latent period (days)	18								
Dog to dog transmission†									
Age at inoculation	*In utero*	12–40 days	Adult	*In utero*	Newborn	3–7 weeks	Adult	3 days	6–8 weeks
Number tumours/number inoculated	28/28	0/8	1/2	6/6	8/12	8/21	0/4	2/3	0/4
Tumour latent period (days)	12–18	—	18	20	7–20	10–27	—	24	—

* The inoculum used was a homogenate from a second transplant generation kitten tumour.

† The inocula used for the first transplant generation were homogenates of puppy tumours that had been induced prenatally with kitten tumour homogenate; those for the second generation were from puppy tumours that had been induced prenatally in the first transplant generation; those for the third generation were from puppy tumours that were induced postnatally in newborn puppies in the second transplant generation.

sarcoma induction was obtained with Moloney concentrates in first passage in seven of eight, and in second passage in eight of sixteen, young kittens after latent periods ranging from 14–30 days (Table 2). In addition, one adult cat developed a fibrosarcoma at the site of intravenous injection of the virus concentrate after a latent period of 30 days.

The transmissibility to kittens of the original donor cat tumour was later confirmed by one of the authors (C.R.): all twenty-two newborn kittens in three serial passages developed fibrosarcomas following inoculation with homogenates and cell-free Moloney concentrates prepared from the original donor cat tumour or spleen.

Cat to Dog Tumour Transmission

Subsequent experiments revealed that puppies were also quite susceptible to sarcoma induction by transmission of cat tumour homogenates (Table 1) or cell-free concentrates (Table 2). Following the *in utero* inoculation of cat tumour homogenate into six dog foetuses at 45 days gestation, all six puppies developed large fibrosarcomas within two weeks after birth. Homogenates of these prenatally induced puppy sarcomas were similarly inoculated into twenty-eight foetuses of five pregnant bitches, at about 45 days gestation, and also into eight young puppies and two adult dogs. In addition, Moloney procedure cell-free concentrates of these same puppy sarcomas were inoculated into eight foetuses of two other pregnant bitches. All thirty-six foetuses had tumours at birth or within the first week of life. Only one of the postnatally inoculated dogs, an adult, developed a tumour. This was first noted after 18 days, and 5 weeks later it had completely regressed.

A second dog to dog transplant generation (Table 1), using inoculum from selected prenatally induced tumours, led to tumour "takes" after 7–27 days in six of six foetuses, eight of twelve newborn puppies, eight of twenty-one puppies age 3–6 weeks, and none of four adult dogs. A third transplant generation (Table 1), using inoculum from selected newborn induced tumours, produced "takes" after 24 days in two of three puppies, age 3 days, but no tumours resulted in the older puppies. In two adult dogs small tumours developed after 23 days which promptly regressed. Attempts to establish continuous dog to dog tumour transplants in weanling or older puppies are in progress. A cell-free Moloney concentrate prepared from a second transplant generation kitten fibrosarcoma induced fibrosarcomas at the site of intramuscular inoculation in four of five two-day-old puppies after an incubation period of 13 days (Table 2). Subsequent inoculations employing these tumours as the challenge material failed to induce tumours in four dog foetuses, fourteen puppies age 2 days to 2 weeks and one adult dog. The donor tumours failed to reveal C-type particles by the electron microscopy described here.

Puppy tumours induced by the cat tumour homogenates, as well as by the cell-free virus concentrates, have been subcultured and cells analysed for chromosome configuration; all proved to be dog karyotype.

The cat and dog tumours induced *in utero* or in newborns have shown progressive growth, often to large size (up to 250 cm^3). Because of the rapid tumour growth it has been possible to keep only a few of the kittens and puppies alive for more than several weeks after onset of tumour development. All the tumours in kittens and puppies were morphologically and microscopically similar to the original donor tumour. An extensive lymphocytic infiltrate was present in the uterine wall sarcoma from the initial mother cat and in the transplant tumours developing in puppies age 4–6 weeks, but not in those tumours developing in foetuses or newborn puppies. Multiple metastases have been noted in several of the kittens and puppies which were inoculated as foetuses or newborns but not in the older animals.

Occurrence of C-type Particles in Tumours

Numerous C-type particles were present in the fibrosarcoma from the original donor cat as well as in the spleen, bone marrow and mesenteric lymph node. Electron microscopic survey of tissues from fourteen kittens and two adult cats bearing either tumour homogenate or cell-free induced fibrosarcomas has revealed C-type particles in systemic distribution as follows: Tumour (16/16), bone marrow (12/12), mesenteric lymph node (11/11), thymus (7/7), spleen (6/8) and submaxillary gland (3/3). Equally numerous C-type particles were present in the same tissues from two puppies inoculated prenatally with kitten tumour homogenate. Fewer C-type particles were found in four dog tumours induced *in utero* and in newborn puppies by homogenates of prior prenatally induced dog tumours, and also in two dog tumours induced *in utero* by cell-free concentrates of prenatally induced dog tumours. C-type particles were not seen, however, in the tumours of two puppies that were inoculated when two days old with kitten tumour cell-free concentrate, nor in one of the six week old puppies bearing a transplant of a prenatally induced dog tumour.

A fibroblastic outgrowth from one second transplant generation kitten tumour has been maintained in tissue culture through four passages. C-type particles were observed at the fourth passage and a cell-free Moloney concentrate of the third passage cell pack induced a sarcoma two months after inoculation into a 15-day-old kitten. This tumour also contained C-type particles.

Partially purified Moloney concentrates of the experimentally induced feline and canine tumours induced cell transformation within 3–5 days in secondary monolayer cultures of feline embryo fibroblasts (P. S. S., M. B. G., and R. J. H., manuscript in preparation). The transformed cells were fibroblastic and refractile with parallel and criss-cross orientation; the latter was generally not readily obvious. Refractile round cells were also found in these cultures. Serially transmissible focus forming virus was also readily recovered from monolayer cultures of transplanted feline sarcomas.

Table 2. TRANSMISSION OF FELINE FIBROSARCOMA WITH CELL-FREE MOLONEY CONCENTRATES

	Passage I				Passage II	
	Cat to cat transmission*					
Age at inoculation	1–23 days	Adult			7 days	1–2 months
Number tumours/number inoculated	7/8	1/1			5/8	3/8
Tumour latent period (days) measured from time of inoculation	15–30	30			22–27	14–24
	Cat to dog transmission†					
Age at inoculation	2 days					
Number tumours/number inoculated	4/5					
Tumour latent period	13					
	Dog to dog transmission ‡					
Age at inoculation	*In utero*	2–12 days	1–2 months	Adult		
Number tumours/number inoculated	8/8	0/12	0/5	0/3		
Tumour latent period	9–12	—	—	—		

* The inocula used for the first and second cell-free tumour passages were prepared from the first and second transplant generation kitten tumours.

† The cell-free inocula used were prepared from a pool of two second generation kitten tumours (litter mates).

‡ The eight puppy tumours induced *in utero* developed after the inoculation of a cell-free concentrate prepared from prenatally induced puppy tumours of Table 1 (containing C-type particles). The same inocula failed to induce tumours in three young puppies and one adult dog. Cell-free inocula prepared from puppy tumours (containing no detectable C-type particles) that had been induced at two days of age with the second generation kitten tumour cell-free concentrate failed to induce tumours in the other postnatal dogs. Homogenates prepared from these identical puppy tumours (induced by the same kitten tumour concentrate) also failed to induce tumours in four other prenatally inoculated puppies (not shown).

Table 3. DETECTION OF FELINE RNA TUMOUR VIRUS COMPLEMENT FIXING ANTIGENS, ANTIBODIES AND C-TYPE PARTICLES IN DOGS AND CATS

A. Dogs

	Complement fixing antibodies against feline RNA tumour virus antigens*	Antibody titre range	Complement fixing of the feline RNA tumour virus group in tumour and/or spleen	Antigen titre range	C-type particles in tumour
Cat to dog sarcoma transplants *in utero*	0/3		2/3†	1 : 8 – 1 : 16	2/2
Cat to dog sarcoma cell-free passage age 2 days	1/4‡	1 : 40	3/3	1 : 2 – 1 : 16	0/2
Dog to dog sarcoma transplant *in utero* of prenatal induced sarcoma	1/6	1 : 40	11/12§	1 : 16 – 1 : 32	2/2
Dog to dog sarcoma cell-free passage *in utero* of prenatal induced tumour	Not tested		5/6	1 : 8	2/3
Dog to dog sarcoma transplant postnatal of prenatal induced tumour	12/20‖	1 : 40 – 1 : 80	1/3	1 : 16	3/4¶
Normal dog	1/4	1 : 40	0/1		Not tested

B. Cats

	Complement fixing antibodies against feline RNA tumour virus antigens*	Complement fixing antigens of the feline RNA tumour virus group in tumour and/or spleen	Antigen titre range	C-type particles in tumour
Feline lymphoma, naturally occurring	0/8	5/5§	1 : 4 – 1 : 16	4/8
Feline sarcoma, naturally occurring	0/5	2/5	1 : 2 – 1 : 4	1/5
Cats with FSV sarcoma transplants	0/6	6/6§**	1 : 2 – 1 : 8	10/10
Cats with FSV sarcomas, cell-free passage	0/5	3/5	1 : 2 – 1 : 8	6/6
Normal cats	0/10	1/10§	1 : 2	0/7

* Antigens tested against included extracts and/or cell-free Moloney concentrates from four prenatally induced feline sarcoma virus puppy sarcomas, from feline embryo fibroblasts cell packs infected with feline leukaemia virus, and from the spleen of a cat with spontaneous lymphoma. C-type particles were present in each of these tissues used for antigen preparation.

† CF reaction positive after ether treatment of antigens.

‡ This positive dog serum was used at a 1 : 10 dilution as the standard antisera for detection of the RNA tumour virus antigens in the tumour and/or spleen extracts shown.

§ The standard dog antiserum generally reacted in higher titre with antigens prepared by the Moloney procedure than with aqueous extracts.

‖ Most of these dog sera reacted in equal titre to either aqueous extracts or Moloney concentrates prepared from a prenatally induced dog tumour.

¶ The three positive tumours are from newborn inoculated puppies; the negative tumour is from a puppy inoculated at 6 weeks of age.

** Complement fixation reaction negative after ether treatment of antigen.

Serological Detection of Tumour Virus Antigens

Preliminary serologic studies indicate that dogs bearing feline sarcoma virus induced fibrosarcomas may provide a heterologous host system for production of antibody suitable for detecting the feline RNA tumour virus antigens in the complement fixation test (Table 3*A* and *B*). Ten per cent aqueous extracts, sonicated and clarified, were prepared from tumour and spleen of kittens and puppies with transmitted sarcomas, from cats with naturally occurring lymphoma and sarcoma, and from feline embryo fibroblast cell packs infected with feline leukaemia virus. Individual dog sera at 1 : 10 dilution were tested for complement fixation antibody versus a 1 : 4 dilution of these tissue extracts (Table 3*A*). Sera from one tumour bearing puppy inoculated at two days of age showed good complement fixation activity and did not show significant reaction with normal cat or dog tissue. This dog serum has been used for detecting feline RNA tumour virus complement fixation antigens directly in spleen and tumour extracts from cats with naturally occurring lymphoma or sarcoma (Table 3*A*) and in feline embryo fibroblast cultures following *in vitro* propagation of feline leukaemia virus. (P. S. S., R. J. H., and J. Baskar, manuscript in preparation). Sera from eighteen other puppies bearing tumour transplants for 4–6 weeks are being tested at weekly intervals and several have developed sufficiently high titred antibody responses to be useful for detection of antigen in feline tumour tissues and in infected tissue cultures. The specificity of the complement fixation reactions for either virus envelope antigens and/or internal group specific antigens is still undetermined, but some of the sera react with soluble ether treated antigens and are therefore presumably detecting group specific antigens. Using the canine serum we have detected the feline RNA tumour virus antigens in a total of sixteen cats bearing tumours (C-type particles were in fifteen) having either experimentally induced sarcoma or naturally occurring lymphoma or sarcoma (Table 3*B*). None of the sera from these cats has revealed complement fixation antibodies to these antigens. This apparent immunologic tolerance for homotypic antibody production may reflect vertical transmission and embryonic antigenic expression of the feline RNA tumour virus genome in the cat, an eventuality that might be expected from recent observations of natural tolerance in mice and chickens to the group specific antigen of their respective homotypic C-type genomes[10,11].

It is clear from the transmission experiments with cell-free concentrates in kittens and puppies and the *in vitro* transformation of feline embryo fibroblasts that certain naturally occurring sarcomas of domestic cats contain competent, fully infectious feline sarcoma viruses. The *in utero* passage of virus containing tumour cells and/or cell-free concentrates into kittens and puppies may offer a particularly useful method for *in vivo* propagation of highly tumorigenic sarcoma virus. The newborn host may also be tolerant to the infectious virus, thus accounting for the high potency and remarkably short latent period of the virus when transmitted to newborn kittens and puppies. Cell lines derived from tumours in these animals also provide potent sarcoma inducing preparations. By contrast, older cats and dogs have proved to be much less likely to develop tumours and the few tumours that did occur were of smaller dimensions and underwent regression in several adult dogs. In spite of the absence of detectable C-type particles the detection of antigen in several tumours that had been induced in two day-old puppies indicated that these tumours may contain the internal nucleocapsid group specific antigen (refs. 7, 12 and unpublished data of R. J. H., M. B. G., P. A. and J. D. E.) of the feline virus. The recent development of complement fixation tests for the antigens of the feline C-type RNA virus, and of sensitive *in vitro* assay systems for infectious virus[11], should make possible sero-epidemiologic studies to determine the natural history of the feline RNA tumour virus.

Sexual Differentiation of the Brain: Effects of Testosterone on Brain RNA Metabolism in Newborn Female Rats

by

RNA metabolism in two regions of the amygdala and anterior hypothalamus of the brain of the newborn female rat responds to testosterone administration quite differently from that in the brain as a whole. These two regions may represent primary sites for the action of this hormone on the brain.

IN adult male rodents, manifestations of sexual differentiation under the influence of the testis, for example, the acyclic pattern of gonadotropin release, appear early in development[1-3]—for the rat, in the first week after birth. The normal course of male behavioural and neuroendocrine development can be simulated in the female by the administration of testosterone propionate during this sensitive developmental period. Several lines of evidence[1-3] support the fact that the major sites of these differentiative processes lie within the central nervous system rather than in peripheral structures. In the brains of male and female animals many experiments have demonstrated the presence of neural receptors for the sex hormones which are involved in the activation of behavioural[4] and neuroendocrine[5,6] control mechanisms. Despite the large amount of experimental evidence that these and other studies have provided, however, there is limited information on the anatomical localization of sites at which the sexual differentiation of the brain occurs, and there are no observations that might relate to the biochemical basis.

We began with the assumption that the early effects of testosterone in the brain would involve enhanced RNA synthesis in differentiating areas and we used autoradiographic methods to examine the acute effect of testosterone on the incorporation of ^{3}H-uridine into the brain RNA of the newborn female rat. A similar approach to cerebral differentiation has recently been outlined by MacKinnon *et al.*[7] although the results did not concern hormonal effects.

We now demonstrate that testosterone reduces significantly the incorporation of uridine into brain tissue in general, but in two localized regions—the anterior hypothalamus and the amygdala—this reduction is not evident. These two regions of the brain have been implicated by others in functions of the central nervous system related to sexual activity and gonadatropin release. Our experiments suggest that they are directly involved in sexual differentiation.

Eight female Sprague-Dawley rats, 2 days old, were obtained from two litters and were divided into two groups of four. To minimize the effects of stress and handling, the cages containing the two litters with their mothers were brought into the laboratory at the end of the day preceding the experiment and the young were removed from the cages and placed in a container at 37° C early on the day of the experiment. Experimental animals were injected subcutaneously with 50 µg testosterone dissolved in 20 µl. propylene glycol. Controls received 20 µl. propylene glycol. After 3 h (a period chosen by analogy with results[8] for the time-course of action of testosterone on RNA synthesis in the seminal vesicles of the rat) each animal was injected with 250 µCi ^{3}H-uridine (specific activity about 2 Ci/mmole, in 10 µl. physiological saline). Exactly 1 h later the animals were cooled in ice for 5 min and then decapitated. The roof of the cranium was quickly cut away and each head was then placed in ice-cold Carnoy's fixative. These operations were carried out alternately on animals from the two groups. The heads were kept in the ice-cold fixative for 6 h. Brains were then dissected out and placed in absolute ethanol at room temperature for 12 h. The ethanol was changed every 4 h. The tissues were cleared in toluene for 3 h with changes of the solvent every hour. Then they were placed in paraffin (m.p. 45°–55°) at 59° with three changes at 1 h intervals, and embedded in the same medium. Each complete brain was serially sectioned transversely at 7 µm intervals.

The sections were mounted in sets of twelve on slides that had been treated with albumin; paraffin was removed in xylene and washing with a succession of alcohols followed finally by running deionized water ensured removal of all soluble radioactivity. The slides were dipped into Kodak 'NTB-3' emulsion kept at 43° C in complete darkness. They were drained, dried at room temperature for 3 h, then stored at 2° C in air-tight, light-proof boxes containing small amounts of 'Drierite' enclosed in paper packages. After 1 week, the slides were developed in 'Dektol' at 18°–20° C for 2 min, rinsed in deionized water, then fixed in Kodak rapid fixative for 5 min followed by a further rinse in deionized water for 15 min. The sections were stained by standard procedures with chrome–alum haematoxylin, counterstained with metanil yellow and, after being taken through a series of alcohols to xylene, were mounted in 'Permount'.

Specific regions of each brain were selected for counting silver grains (Figs. 1*a*–*d*). Grain counts were made at × 1,200 magnification under oil immersion with the aid of a net reticule placed in one eyepiece of the binocular. Most of the label in our experimental conditions was associated with the cell nuclei. For each given area, ten to eighteen sections were counted at intervals of two or three sections. The grains per nucleus were counted for fifty cells per section, as dictated by the alignment of the reticule. The results obtained by one observer were confirmed by a second working without knowledge of the experimental group from which the slides were derived.

For the purpose of direct radioassay of incorporated ^{3}H-uridine into brain tissue, the procedure was identical up to the point of transfer of the brain from the fixative into absolute alcohol. The brain was then homogenized in this solvent and insoluble material sedimented by centrifugation, then re-extracted five times with 70 per cent ethanol. The solid residue recovered from the last extraction was then dried for one week over phosphorus pentoxide *in vacuo*, and a weighed portion dissolved in hyamine. The hyamine solution was mixed with 15 ml. scintillation fluid containing 2,5-diphenyloxazole (5 g) and 1,4-*bis*-2-(5-phenyloxazolyl)benzene (0·3 g) per 1. of toluene, and its ^{3}H content assayed in a Packard liquid scintillation spectrometer. Heavy quenching by hyamine and yellowing of the samples made it necessary to ascertain the efficiency of counting of each sample by subsequent addition of $0{\cdot}89 \times 10^5$ d.p.m. ^{3}H-toluene (50 µl.) to

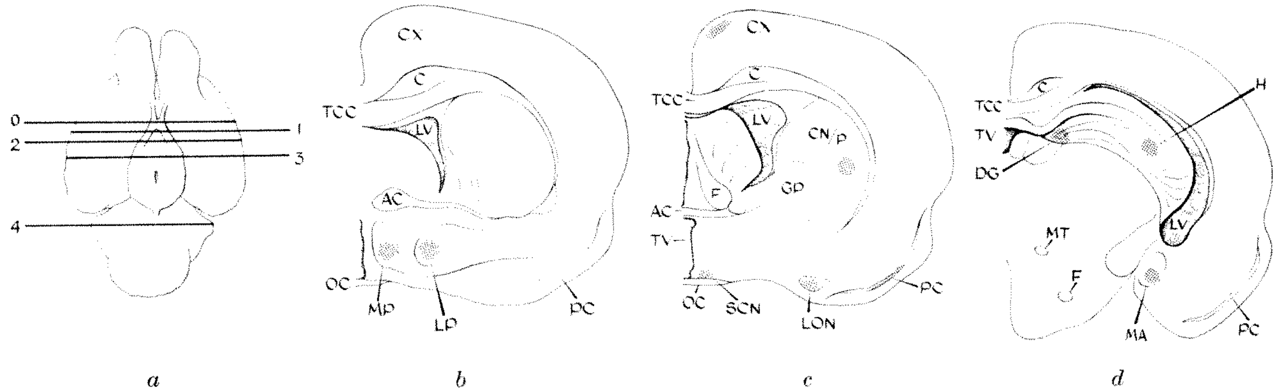

Fig. 1. Regions of the brain of the newborn female rat selected for autoradiographic measurements of incorporation of ^{3}H-uridine. *a*, General ventral aspect of the brain indicating levels of sectioning (1–3) represented in *b*, *c* and *d* respectively, and a cerebellar section (4), not shown. The line "O" represents a point of reference, the anterior limit of the optic chiasma. The stippled areas in *b*, *c* and *d* indicate areas selected for counting silver grains. AC, Anterior commissure; C, corpus callosum; CX, cortex; CN/P, caudate nucleus-putamen; DG, dentate gyrus; F, fornix; GP, globus pallidus; H, habenula; LV, lateral ventricle; LON, lateral olfactory nucleus; LP, lateral preoptic area; MA, medial amygdala; MP, medial preoptic area; MT, mamillothalamic tract; OC, optic chiasma; SCN, suprachiasmatic nucleus; TCC, truncus corporis callosi; TV, third ventricle.

each sample followed by re-assay. All assays were conducted in conditions which gave results well within 99 per cent confidence limits.

To demonstrate that the radioactivity incorporated into the tissue was in fact present in RNA, the histological sections and the extracted tissue residues were treated as follows. Before being dipped in the photographic emulsion they were exposed for three periods, each of 1 h, to a solution of bovine pancreatic ribonuclease (Mann, 5× crystallized) in water (0·3 mg per ml.) alternating with 1 h periods of rinsing in running deionized water. The sections were finally rinsed overnight in running deionized water, then dipped into the photographic emulsion. Subsequent handling was identical with that for other sections. Residues of brain tissue after homogenization and extraction with alcohols were treated with ribonuclease analogously. Weighed samples were triturated with the enzyme solution (1 mg per ml. water: about 0·5 ml. solution per mg tissue residue) and allowed to stand at room temperature for 1 h. The residue was then precipitated by centrifugation, the supernatant enzyme solution removed, and the sediment washed by resuspension in distilled water followed by recentrifugation. This was repeated twice and the final washed residue was again dehydrated with alcohol before radioassay of weighed, hyamine-solubilized portions. The enzyme treatment removed 80–90 per cent of the label and no significant differences in the residual label could be detected between experimental groups.

It was essential that the brains were kept as close as possible to 0° C while being exposed within the cranium and during fixation. Otherwise, great variations in grain counts were observed between animals of the same experimental group, and different areas of the brain showed wide and irreproducible fluctuations of incorporated radioactivity, probably because of enzymic breakdown of newly synthesized RNA which may occur to varying degrees in non-cooled tissue.

The cortical neurones, and in particular those of the lateral olfactory nucleus, were the most heavily labelled (Fig. 2). All other areas, including the medial preoptic area and medial amygdala, were more uniformly labelled, the grain intensity being different from that in the cortex and lateral olfactory nucleus. (Note that the cell nuclei of the lateral olfactory nucleus are probably the largest of all neuronal nuclei in animals of this age.) The incorporation of label (Fig. 2) is significantly ($P = 0{\cdot}05$–$0{\cdot}01$) lower in nine of the eleven areas studied in the testosterone-treated animals than in the controls. For the two exceptional areas, the medial preoptic area and the medial amygdala, the mean values in the testosterone-treated group were slightly higher than in the propylene glycol treated controls, but the difference between the two groups in these two areas was not significant. An analysis of variance of all results showed that the differential response (testosterone-treated compared with control) in the medial preoptic area and the amygdala differed significantly ($P < 0{\cdot}01$) from the response of other areas of the brain.

These results suggest that testosterone generally diminished uridine incorporation throughout the brain, the medial preoptic and amygdaloid areas behaving exceptionally. Possibly, however, the nine limited areas in which less incorporation was observed were not representative of the behaviour of the brain in general. To rule out such a possibility, the incorporation of labelled uridine was studied by direct tritium assay of the insoluble residue of the individual whole brains of groups of animals treated exactly as in the histological experiments. Each experimental group comprised eight newborn females. The mean

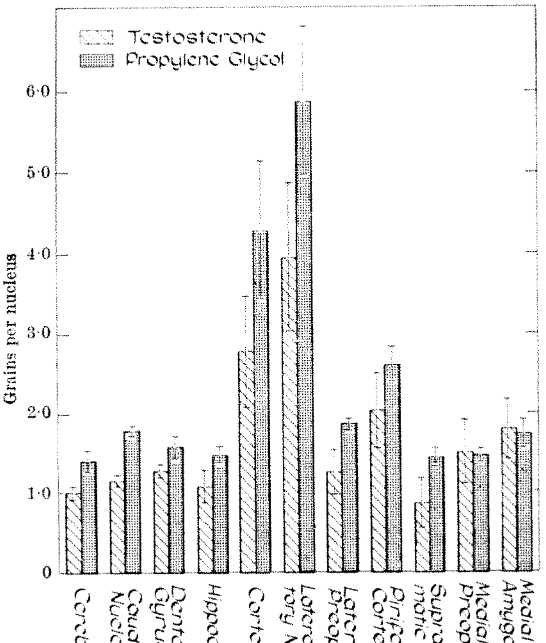

Fig. 2. Regional distribution of labelling of the brains of neonatal female rats by incorporation of ^{3}H-uridine, with and without previous treatment with testosterone. Each bar represents the mean grain count per cell ($\pm$ *S.D.*) in a given area for four animals. The value for each animal was the mean of the grain counts per cell over a number of histological sections (see text).

specific activity (±*S.D.*) of the RNA-containing residue of the brain tissue in the testosterone-treated group was 8,444±1,698 while in the control group it was 10,511±1,543. These values are different with a level of significance ($P=0·05–0·01$) of the same order as that established by the autoradiographic measurements, with the exception of those for the medial preoptic and medial amygdala, which must therefore differ from the rest of the brain in their response to testosterone.

The basis of the action of testosterone on nucleic acid metabolism in the neonatal brain is obscure. It may involve the activation by testosterone of a number of peripheral metabolic systems that take up uridine so that less of the labelled material is available to the brain. Fujii and Villee[9] found enhancement of RNA synthesis in the liver of immature rats following testosterone administration, but preliminary attempts on our part to account for the results found in the brain in terms of enhanced hepatic RNA synthesis have been inconclusive. A direct general effect of the hormone on some pathways of uridine metabolism in the brain, the result of which is overridden by a more specific type of response in the medial preoptic and amygdala, is also a possibility.

The divergence of the results obtained in the medial preoptic and amygdaloid areas from those found in the brain as a whole is of special interest. If, for whatever reason, less ^{3}H-uridine is available for the brain of the testosterone-treated animal than for the control, the failure of this effect to be registered in these two areas can best be explained as a specific local enhancement of incorporation which would be expected in neurones undergoing sexual differentiation. But even this interpretation is necessarily tentative. For example, we do not overlook the fact that measurements made by autoradiography cannot reflect dynamic aspects of nucleic acid metabolism and both synthesis and degradation of RNA may be affected. Numerous other observations make it reasonable to suggest, however, that either or both the preoptic area and the amygdala is intimately involved in the process of sexual differentiation of the brain. Implantation of pellets of oestradiol into the medial preoptic area of the oophorectomized rat reinstates sexual behaviour[10]. Lesions in the preoptic area cause disruption of cyclic control of gonadotropin release[11–14] and of normal female sexual behaviour[15,16]; electrical stimulation of this area can induce ovulation in the normal female[17,18] but not in the female treated neonatally with a single injection of testosterone propionate adequate to abolish both cyclic behaviour and female receptivity[19]. Cyclicity is also abolished by the severance of neural connexions between the medial preoptic area and the median eminence region[20].

Lesions in the amygdala were reported many years ago to result in changes in aggressive behaviour and a greatly increased interest in sexual activity[21,22]. In the infant rat, bilateral lesions in the amygdala[23] or transection of the stria terminalis[24], a principal pathway between the amygdala and the preoptic area of the hypothalamus, resulted in precocious ovarian stimulation. Conversely, stimulation of the amygdala in the young female rat was reported[25] to delay the onset of puberty. According to a recent report, androgen-induced precocious puberty in female rats is also inhibited by lesions in the ventrolateral hippocampus (adjacent to the medial amygdala)[26].

This study was supported by a grant from the US Public Health Service to R. B. C. We thank Dr. C. T. Sehe for help in initial studies of the autoradiographic techniques, and Miss Elizabeth Gautreux and Miss Dian Degnan for technical assistance.

Localization of Choline Acetyltransferase

The techniques for the histochemical detection of choline acetyltransferase, outlined in the following articles, will facilitate studies of the intracellular organization of cholinergic neurones and their distribution in the CNS.

Histochemistry at the Light Microscope Level

THERE has long been a need for a histochemical method for locating the enzyme choline acetyltransferase (acetyl-CoA : choline *O*-acetyltransferase, EC 2.3.1.6). It would provide valuable information on two difficult questions in particular. The first concerns the intracellular location of the enzyme and what position it occupies at the endings of cholinergic neurones. A reliable histochemical method should settle this and also help to resolve the problem of the intracellular transport of acetylcholine (ACh), from sites where it is synthesized to those—presumably the synaptic vesicles—where it is stored[1]. The second question is how to establish with certainty which central neurones are cholinergic. At present we depend largely on the histochemistry of acetylcholinesterase (EC 3.1.1.7) to determine which central pathways are cholinergic; but the distribution of this enzyme does not run parallel in all parts of the CNS with that of ACh, and its presence in high concentrations in tissues such as the cerebellum may have some other significance. On the contrary, from all that is known of the distribution of choline acetyltransferase it can be expected to give a surer indication of the distribution of ACh and hence of cholinergic neurones[2].

We have tested one possible histochemical method originally proposed by Burt[3], in modified conditions[4]. Thin sections of tissue are incubated in the presence of acetyl-CoA (ACoA), choline and a lead salt. Because acetylcholine is formed by the catalytic action of choline acetyltransferase, free CoA—which contains a sulphydryl group—is released and precipitated in the vicinity of the enzyme by the lead present in the solution. The precipitate so formed can then be converted to lead sulphide, which is readily seen under the microscope, by treatment with sodium sulphide (*p*H 7·5). As controls one or both substrates are omitted from the incubation mixture.

Many other reactions could, of course, lead to the release of free CoA from ACoA and it is therefore important to show that the formation of the histochemical end-product is choline-dependent. This was evidently not the case in Burt's experiments, for he reported that the reaction rate was only halved when choline was omitted from the medium: he suggested that this represented hydrolysis of ACoA by choline acetyltransferase in the absence of choline.

An alternative, or additional, possibility is that some hydrolysis of ACoA was catalysed by the acetylcholinesterase present in the tissue, for he did not include an anticholinesterase in his substrate mixture. We have found that a commercial preparation of bovine erythrocyte acetylcholinesterase readily hydrolyses ACoA (measured as described by Chase[5]), and that this can be prevented by eserine. In our modified system[4], the tissue sections (of rat spinal cord and spinal ganglia) were therefore pre-incubated with eserine, in a concentration of approximately 10^{-4} M, and eserine was also added to the substrate mixture which contained the following (in mM): eserine sulphate, 0·13; cacodylate buffer (*p*H 5·9), 33·0; ^{14}C-acetyl-CoA, 0·67; choline chloride, 10·0; and lead nitrate, 0·1. Radioactive ACoA was used so that the amount of ACh which formed in the incubation medium could be monitored.

The results of tests using this system showed that on average eserine considerably reduced the rate of reaction, and the degree of staining, in the absence of choline. The effect was variable, however, and in some sections of spinal cord fairly marked positive staining was obtained after incubation without added choline. Moreover, some cells from other parts of the nervous system, which according to biochemical measurements should contain little or no choline acetyltransferase, unexpectedly gave a positive reaction. For example, the Purkinje cell bodies in the cerebellum were regularly positive, and, somewhat more variably, some or most of the spinal ganglion cells became stained to some extent.

Clearly some staining occurred, or could occur, independently of the catalytic action either of choline acetyltransferase or of acetylcholinesterase and we decided to follow the rate of hydrolysis of ACoA when it was incubated with rat brain homogenate and with no added choline at 39° C. In these conditions there was a steady loss of ACoA, which did not occur if ACoA was incubated without the homogenate. The rate of loss of ACoA, which was found to be associated with the release of free acetate, was considerably depressed by 10^{-4} M eserine, but the rate of breakdown of ACoA was still substantial. Ascribing this to the action of esterases other than the cholinesterases, we investigated the effect of increased concentrations of eserine (up to 10^{-2} M) and of sodium fluoride (up to 3×10^{-2} M) added with or without eserine, both of which should inhibit some of the normally eserine-resistant esterases. Neither in fact had any significant effect on the rate of hydrolysis beyond what was achieved by 10^{-4} M eserine.

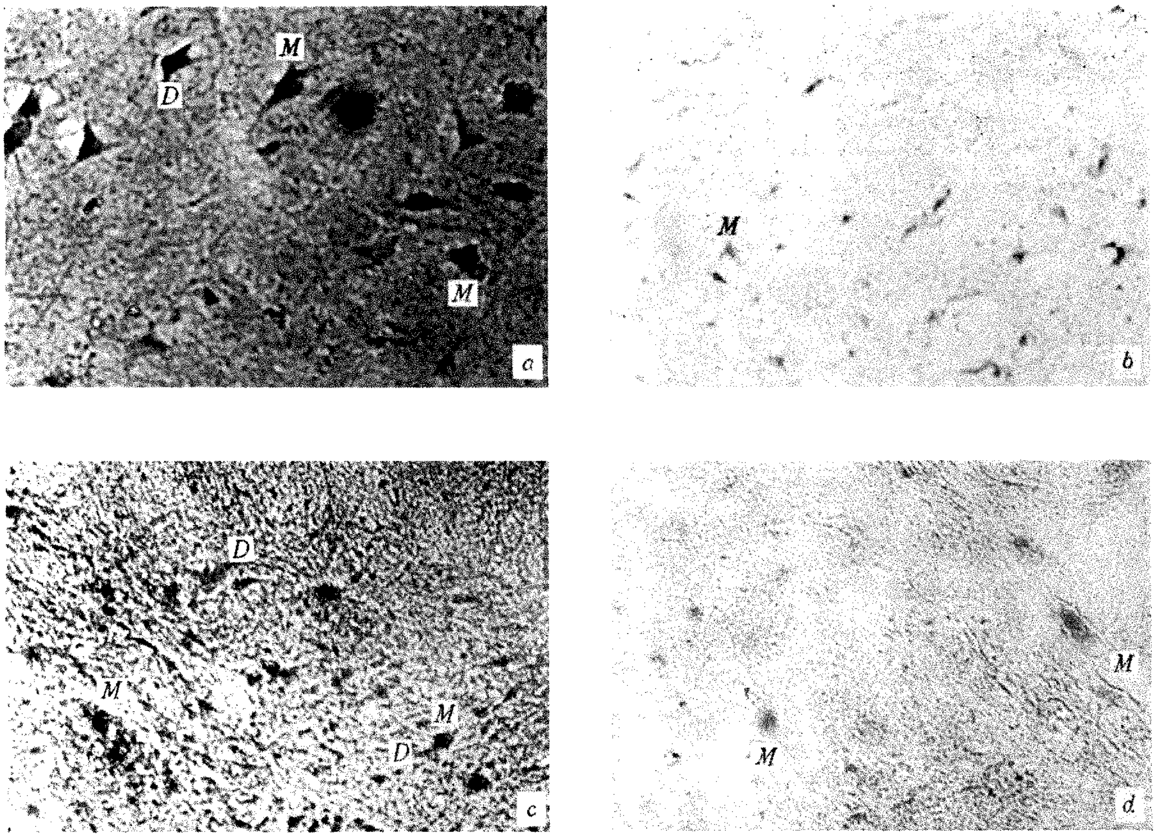

Fig. 1. Sections of rat spinal cord. *a* and *c*, incubated in the presence of DFP, ACoA, choline and lead; *b* and *d*, choline omitted. *a* and *b* were unfixed and incubated 4 h; *c* and *d* were fixed in 1 per cent formaldehyde before being incubated for 5 h. All sections were pre-incubated with DFP (10^{-3} M) for 30 min. *D*, Dendrite; *M*, motoneurone. ×240.

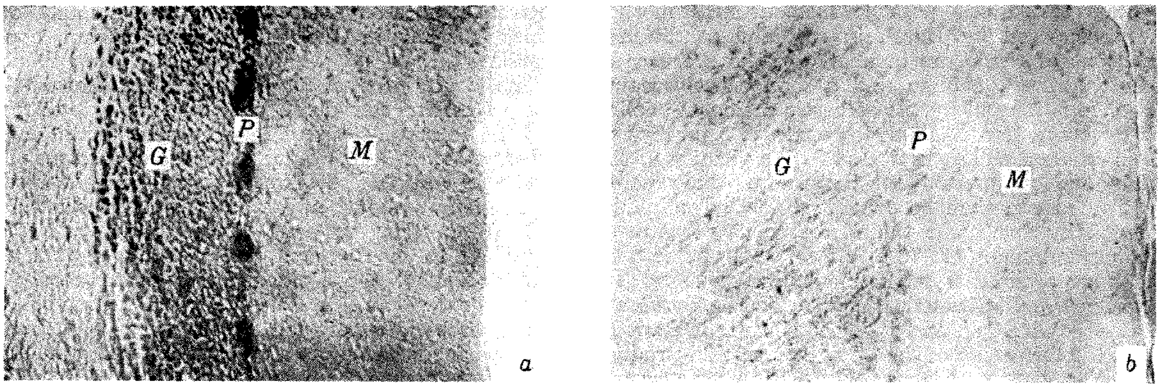

Fig. 2. Sections of rat cerebellar cortex, fixed with formaldehyde. *a*, Incubated with eserine, ACoA, choline and lead. There is marked staining of the Purkinje cells (*P*) and some of the granular (*G*) and molecular (*M*) layers. Incubation time, 5 h. *b*, Incubated in the presence of DFP, ACoA, choline and lead. Note that the Purkinje cells are not stained but slight activity remains in the granular (*G*) and molecular (*M*) layers. Incubation time 5 h. ×240.

We next examined di-isopropylfluorophosphate (DFP). Like eserine, in the concentrations which ensured the complete inhibition of acetylcholinesterase (10^{-5} to 10^{-6} M) and applied in the same way (including preincubation without the substrate), DFP slowed the rate of hydrolysis of ACoA considerably. More important, when the concentration of DFP was increased it slowed the reaction even more, until at a maximally inhibitory concentration of 10^{-3} M it reduced the rate of hydrolysis by 90 per cent. In view of its effectiveness DFP was then tested in the histochemical procedure. The results were much more clear-cut than with eserine. First, DFP as an inhibitor of the non-specific hydrolysis of ACoA did not interfere with the positive reaction of the ventral horn and other cells containing choline acetyltransferase; while by contrast with the earlier results, the omission of choline was associated with a very considerable reduction in their staining (Fig. 1). Thus the reaction produced in the presence of choline was not likely to have been obscured, or significantly added to, by other uncontrolled reactions, and was therefore probably to be attributed to choline acetyltransferase. Other biochemical tests established that 10^{-3} M DFP had no inhibitory effect on choline acetyltransferase.

Further evidence for the identification of the observed histochemical end-product with the catalytic action of choline acetyltransferase is that with the substitution of DFP for eserine in the incubation mixture, spinal ganglion cells and the Purkinje cells no longer reacted positively (Fig. 2). On the other hand, a number of cells in the red nucleus which may be expected to be cholinergic did continue to react.

How generally applicable and reliable the method will be depends on more extensive tests. It is desirable to fix tissue sections before they are incubated[6], for diffusion of enzyme from fresh frozen sections may lead to its false localization or to widespread deposition of the histochemical end-product. In the case of choline acetyltransferase it is difficult to achieve satisfactory fixation of the tissue without reducing the activity of the enzyme very seriously. Although a positive reaction can be obtained on formalin-fixed tissue (Fig. 1*c* and *d*), this was only achieved with a loss in the sensitivity of the reaction, and this problem has to be overcome. One precaution is to keep the ionic strength as low as possible because choline acetyltransferase is more soluble at high ionic strengths[7]. But this, too, has meant some loss of enzyme activity. Further, the inclusion of lead in the incubation medium and its adjustment at *p*H 5·9 both reduce the enzymic synthesis of ACh appreciably, and this may well mean that the method even when applied to unfixed tissue will not detect choline acetyltransferase at low concentrations. The concentration in nervous tissue is probably much lower than that of acetylcholinesterase, so it is not to be expected that the staining reaction of a given tissue for choline acetyltransferase will be as strong as for acetylcholinesterase even in optimal conditions.

Although we are developing the method for use with the light microscope, it is only at the electron microscopic level that questions about the intracellular location of the enzyme can be resolved. We tentatively suggest that the enzyme may be associated in the cell body with the ribosomes, in the axons with the neurofilaments, and in the nerve endings with some intervesicular material.

Note added in proof. Professor A. M. Burt has recently sent us a copy of an article (*J. Histochem. Cytochem.* (in the press)) describing in greater detail the histochemical procedure of ref. 3. Although his method relies on precipitation of the lead mercaptide of CoA to mark the sites of ACh synthesis, it differs in many important respects from our own. We should point out, however, that in his final procedure, Burt has found it useful to add an anticholinesterase, phospholine iodide.

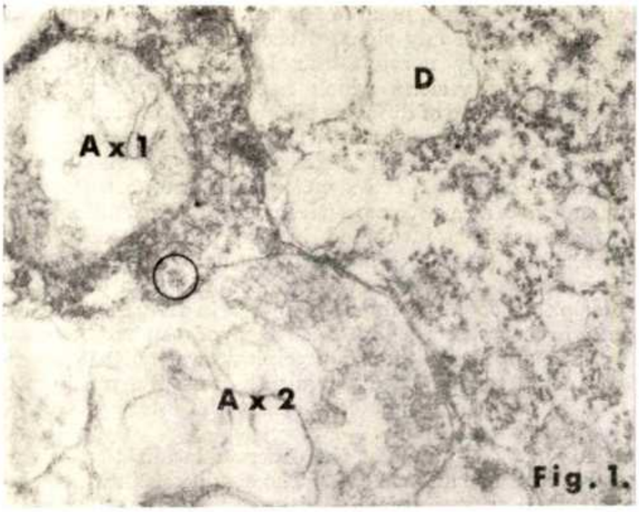
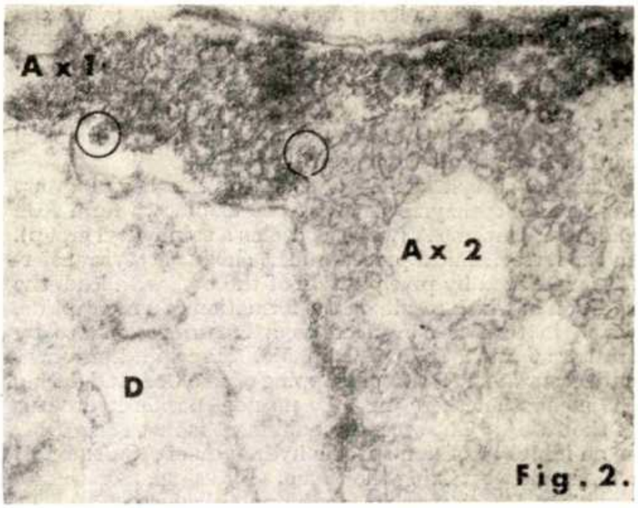
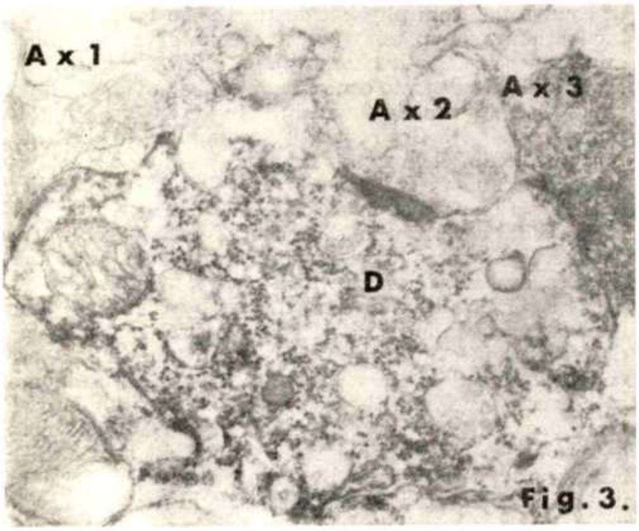
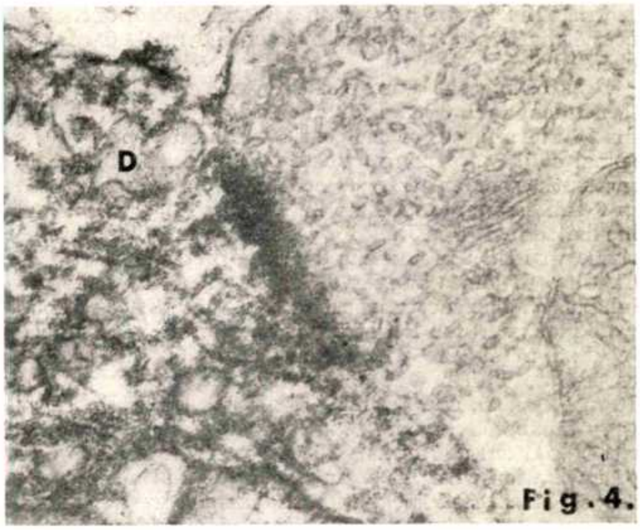
Ultrastructural Localization in Spinal Neurones

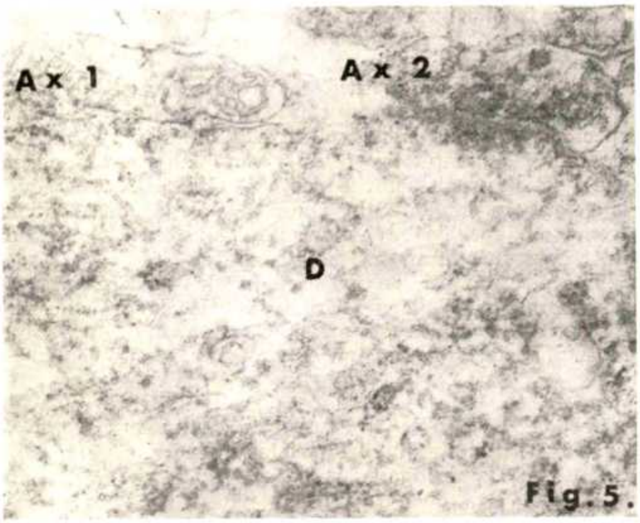
ACETYLCHOLINE (ACh), a chemical substrate for synaptic transmission, is synthesized by choline acetyltransferase, which is present in all cholinergic neurones (and is found as well in some non-nervous tissues[1]). It is detectable in the axon and its terminals and is thought to be in the cell body and dendrites too, but this has never been formally demonstrated although there is evidence that choline acetyltransferase, like most other neuronal proteins, is synthesized in the cell body and transported continuously at a low rate to the axon endings[2,3]. We have described a specific technique, based on that of Burt[4], for the localization of choline acetyltransferase at the light micro-











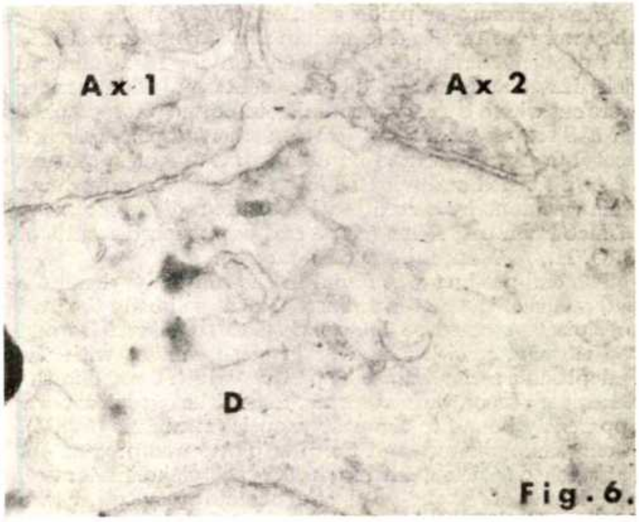


Fig. 1. Electron micrograph of the rat spinal cord. Choline acetyltransferase activity is present in the dendrite (D) and within an axon terminal (Ax 1). At the bottom left is another nerve terminal (Ax 2) which does not exhibit any reaction product. It is not possible to say whether in those vesicles marked by circles here and in Fig. 2 the precipitate is inside or on their surface. The swollen condition of the mitochondria shown in this and other figures results from incubation of the tissue in a hypotonic medium. × 39,000.

Fig. 2. Choline acetyltransferase positive (Ax 1) and negative (Ax 2) nerve terminals in close contact with a choline acetyltransferase negative dendrite (D). Note the reaction product on the outer surface of the synaptic vesicles. For explanation of circles see Fig. 1. Rat spinal cord. × 54,000.

Fig. 3. Much of the reaction product which has formed in a dendrite (D) is attached to the ribosomes and some larger vesicles. On the dendrite three different nerve terminals make synaptic contacts: of two in which there is no reaction product, one (Ax 1) contains a mixed population of synaptic vesicles, the other (Ax 2) contains ovoid vesicles; the third (Ax 3) is choline acetyltransferase positive and possesses round shaped vesicles. Rat spinal cord. × 26,000.

Fig. 4. A choline acetyltransferase positive dendrite (D) synapsing with an enzyme-negative terminal that has ovoid or elongated vesicles. Rat spinal cord. × 41,500.

Fig. 5. Positive dendrite (D) in synaptic contact with a choline acetyltransferase negative terminal (Ax 1) and a positive terminal (Ax 2). Pigeon spinal cord. × 32,200.

Fig. 6. Section of pigeon spinal cord incubated in the presence of ClACh perchlorate to inhibit choline acetyltransferase activity. × 20,400.

scope level[5,6], but to learn more of its position in the cell we need to be able to examine the ultrastructural localization of the enzyme under the electron microscope. To do this we have had to introduce several further modifications of the original technique, and we now report the procedure and illustrate it with results from the spinal cord of the rat and the pigeon.

Choline acetyltransferase transfers the acetyl group from acetyl-coenzyme A (ACoA) to choline to form ACh and free coenzyme A (which contains a sulphydryl group). In the histochemical procedure the choline acetyltransferase is localized by precipitation of the CoA with lead, the addition of which results in the formation of a mercaptide, which in turn is converted to a brown precipitate by treatment with sodium sulphide. Precipitation must only occur as the result of trapping of free CoA and during the incubation there must be no non-specific hydrolysis of the ACoA. The second requirement is met using DFP as an inhibitor of non-specific hydrolysis of ACoA (ref. 6) and the first by fixing the tissue. By using chloroacetylcholine (ClACh) perchlorate (unpublished results of D. Morris, D. S. Grewaal and P. K.) as an inhibitor of choline acetyltransferase, the specificity of the method can be checked.

Rats or pigeons were perfused with 1 or 2 per cent formaldehyde in 0·1 M sodium cacodylate buffer (pH 7·5) for 10 min; pieces of the cervical or lumbar part of the spinal cord were then removed and immersed for 30–60 min in the same fixative; after this the tissue was washed in 0·1 M sodium cacodylate buffer (pH 7·0) for 3 h, and incubated in 10^{-3} M DFP for a further 1 h. Some of the tissue was then preincubated in the presence of 10 mM ClACh perchlorate at pH 7·0 for an additional 30 min to inhibit choline acetyltransferase itself. The samples were incubated for 1 h at 25° C and 3 h at 37° C in the incubation mixture which consisted of 33 mM sodium cacodylate buffer (pH 5·9), 0·67 mM ^{14}C-acetyl-CoA, 10 mM choline, and 0·1 mM $Pb(NO_3)_2$. Control samples were incubated in a similar incubation mixture which either contained 10 mM ClACh perchlorate, following preincubation with the same reagent, or did not contain any choline. After incubation the samples were rinsed in sodium acetate buffer (pH 7·0) and transferred to a buffered sodium sulphide solution (pH 7·5) for 5 min; they were then washed in sodium acetate buffer, postfixed in 1 per cent osmium tetroxide solution[7] for 15–20 min and dehydrated and embedded in the usual way. Thin sections were cut with a Reichert ultramicrotome and photographed on a Siemens 'Elmiskop' electron microscope. Labelled acetyl-CoA was used to be able to measure the amount of ACh formed and released into the incubation medium. This was done by a modification of the radiometric assay of McCaman and Hunt (ref. 8 and unpublished results of C. O. H., A. Maneckjee and D. Morris).

The end-product was found in the cell body, dendrites and axons of the motoneurones. In the cell body the lead precipitate seemed to be attached to some vesicles and the ribosomes, either free or in close contact with the endoplasmic reticulum. The product which formed in the dendrites was on the ribosomes, free in the cytoplasm and apparently bound to the postsynaptic membrane (Fig. 4). Along the axons most of the precipitate was present on, or attached to, the filaments; unlike acetylcholinesterase[9], no evidence of the end-product of choline acetyltransferase was seen in the tubules. In some of the axon terminals (Figs. 1, 2, 3 and 5) evidence of relatively concentrated enzyme activity can be seen, corresponding presumably to cholinergic nerve terminals. The reaction end-product appeared on and between the synaptic vesicles and on the filaments; none could be seen in the mitochondria and very little on the inner surface of the axolemma.

A point of particular interest is that the reaction end-product was evident only in axon terminals which contained round—as distinct from ovoid—shaped vesicles. Not all axons with round vesicles displayed a positive reaction; on the other hand, none of those with ovoid or elliptical vesicles showed any signs of the product. There were, however, many nerve terminals containing predominantly round vesicles which had no enzyme activity. Possibly because of diffusion of the enzyme during incubation, or at an earlier stage, some reaction product was found extracellularly between membranes where one or more belonged to a cell structure, dendrite, cell body or axon, which also gave a positive reaction (Figs. 2, 4 and 5).

Most samples incubated in the presence of ClACh perchlorate (Fig. 6) or in the absence of choline displayed no evidence of enzyme activity. In some, however, lead precipitate could be found in places in the glia cells, on and in between the outer surface of the membranes. But the appearance of this precipitate was quite different and could readily be distinguished from the precipitate seen in samples incubated without the inhibitor and in the presence of choline.

To what extent might the observed localization of the end-product be an artefact ? The conditions in which the enzyme is operating in the histochemical procedure are, of course, far from physiological: the solution used for incubation was hypotonic (which accounts for the swollen appearance of the mitochondria), its pH was considerably lower and its substrate concentration higher than normal, while the salts usually found in living tissue were hardly represented in it. Such conditions could lead to abnormal precipitation of the enzyme and we therefore cannot yet attach too much significance to the detailed localization of the reaction product in the cell. We attach more significance, however, to the evidence of enzyme occurring exclusively in those nerve terminals which contain round vesicles, and not in those which have elongated or ovoid vesicles. It has been suggested, first by Uchizono[10] and later for the spinal cord by Bodian[11], that morphological differences in the synaptic vesicles characteristic of nerve endings may reflect differences in the nature of the chemical transmitter which they contain. Our results fit with this view and suggest that nerve terminals with elongated vesicles are not cholinergic; but that those which contain rounded vesicles may be either cholinergic or non-cholinergic. If it is assumed that in non-cholinergic neurones the elongated vesicles contain a different neurohumour from that present in the round ones, then at least three different transmitter substances may act on the same cell body or dendrite.

In the preceding article[6], we emphasized choline dependence as a necessary condition to be fulfilled if the specificity of the histochemical reaction is to be demonstrated. We emphasize equally that the appearance of the reaction product in the electron microscopy technique is effectively prevented by the use of an inhibitor which seems to be specific for choline acetyltransferase when used in the presence of an anticholinesterase.

The electron microscope used in this research was a gift from the Wellcome Trust. P. K. is a Wellcome research fellow on leave from the Department of Anatomy, Medical University, Szeged, Hungary.

Molecular Mechanics of Translation: a Reciprocating Ratchet Mechanism

by
CARL WOESE
Department of Microbiology,
University of Illinois,
Urbana, Illinois 61801

A model is suggested for protein synthesis which depends upon conformational changes in tRNA and allosteric transitions in place of translocation.

CURRENT understanding of the nature of translation is embodied in the A-site–P-site model of the ribosome. The A site holds the incoming aminoacyl tRNA, the P site the peptidyl tRNA. As a consequence of peptidyl transfer the former tRNA is "translocated" from A site to P site[1,2]. In the past decade much evidence has accumulated consistent with this model, but it remains unproven[2-12]. This is not important, however, for the model in any case is too vague to be of real theoretical value. Clearly, what is needed is a conception of translation specific enough to suggest experiments that will elucidate the molecular mechanics of the process. This article is intended to fulfil this need.

It seems quite impossible to avoid invoking tRNA-like entities (that is, an "adapter" system) as an integral part of translation from its very inception—which is sufficient reason for suspecting the basic molecular mechanics of the process to lie in the properties of this molecular species[13-16]. For this reason it may be of value to examine the anticodon arm of tRNA—that portion of the molecule apparently most directly involved in translation. A structure for this arm has been suggested by Fuller and Hodgson[17]. Because the arm always comprises seventeen nucleotides, the first and last five of which complement one another, it should possess a double helical "stalk" of five base pairs. Fuller and Hodgson maintain that in the most probable overall configuration for the anticodon arm total base stacking is optimized. Sterically this could mean that one of the chains of the double helical stalk continues for five additional residues in a single stranded extension with the same pitch and axis as the stalk proper[17]. Extending either chain in this fashion produces a similar configuration, in which the three anticodon bases reside at the top of the extension. The two possibilities differ, however, in that: (1) extension of the 3′–5′ chain of the stalk causes two purines to underlie the anticodon bases, whereas extension of the 5′–3′ chain causes two pyrimidines to do so; and (2) in the first instance the III* anticodon base is topmost, but in the second it is the I* anticodon base[17]. (These two conformations of the anticodon arm will be referred to as "*FH*" (3′–5′ chain extended) and "*hf*" (5′–3′ chain extended).) The stacking properties of purines, Fuller and Hodgson argue, would cause the *FH* conformation to be energetically favoured*.

Conformational Changes in tRNA

While the argument that total base stacking interactions must be optimized seems reasonable, it should nevertheless be applied not to tRNA (or the anticodon arm thereof) in isolation, but rather to tRNA in the act of translation. In this case one has to consider in addition to the *FH*-type of structure another formation, the duplex of six base pairs potentially formed between the "peptidyl" and the "aminoacyl" codons and their respective anticodons. This sextuplet duplex structure (*SDS*) is compatible with the peptidyl–anticodon, but not the aminoacyl–anticodon arm being in the *FH* conformation. However, were the aminoacyl–anticodon arm to assume the *hf* conformation, a combined *FH–SDS–hf* helix could form. As Fig. 1 shows, these three overlapping helical structures are coaxial, and the "translation complex" they form has an overall length equivalent to twenty base pairs. Since total base stacking energy in such a complex seems greater than would be the total base stacking energy were both the peptidyl and the

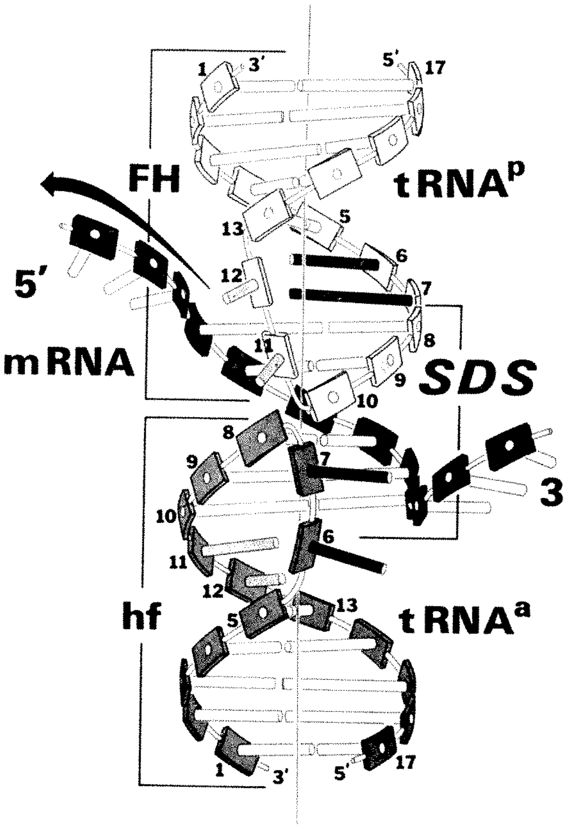

Fig. 1. The basic translation complex. The complex (in essence an RNA double helix the equivalent of twenty base pairs in total length) comprises anticodon arms of both a peptidyl tRNA (tRNA^p) in the *FH* conformation and an aminoacyl tRNA (tRNA^a) in the *hf* conformation, plus their respective codons (combined with the anticodons proper in a central "sextuplet duplex structure" or *SDS*). Bases Nos. 6 and 7 (solid bars) are not paired and are excluded from the helix proper in an *hf* conformation. Bases Nos. 11 and 12 (stippled bars) are similarly unpaired and are excluded from the helix in the *FH* conformation. Numbering of bases is that used in ref. 17. The 5′ and 3′ ends of all chains are shown. mRNA as drawn would move from right to left in translation (indicated by the arrow). The axis of two-fold rotational symmetry (dyad) relating the anticodon stalks is formed by the intersection of two planes; one is perpendicular to the axis of the complex at its midpoint; the other contains that axis and is perpendicular to the bars (base pairs) linking the No. 5–No. 13 positions in either anticodon stalk. See text for further details.

---

* The base pair tilt in RNA double helices also places constraints on these structures, in that bases Nos. 11 and 12, excluded from the helix in the *FH* conformation, and Nos. 6 and 7, excluded from the helix in the *hf* conformation, must span different grooves of the structure. Nos. 11 and 12 span the "major groove" in an *FH* structure, Nos. 6 and 7 span the "minor groove" in an *hf* structure[17].

aminoacyl–anticodon arms in the *FH* conformation, strong support is provided for the idea that during translation the anticodon arm of tRNA undergoes a conformational change—an *hf* → *FH* transition.

A very simple mechanism for message RNA movement and the maintenance of reading frame is inherent in an *hf*→*FH* transition. When paired to an anticodon in the *hf* conformation, a codon lies in the helical strand defined by the 3′–5′ chain of the anticodon stalk (Fig. 1). In this configuration the I base of that codon is topmost, and the preceding codon can lie directly above it (with the same helical pitch and axis). When the *hf*→*FH* transition occurs, however, the codon in question then resides in the other strand of the double helix (that is, the one defined by the 5′–3′ chain of its anticodon stalk) and therefore is inverted, with its III base now topmost. Consequently the preceding codon can no longer share a common axis with this codon, but the succeeding codon now can. This inversion of the codon relative to its anticodon stalk provides a potential mechanism not only for mRNA movement but also for tRNA displacement and strict maintenance of reading frame.

This mechanism is in no way inconsistent with A-site–P-site theory, although it restricts the possible orientations of the two sites, that is, the P site must include the top half of the translation complex as drawn in Fig. 1, the A site its bottom half. These considerations do, however, suggest an entirely different, simpler alternative for the molecular mechanics of translation.

Translation as an Allosteric Phenomenon

"Translocation" of a (more or less static) tRNA molecule from one site to a different kind of site is the essence of the A-site–P-site model. The alternative is an allosteric type of mechanism, in which an essentially antisymmetric dimer undergoes cyclic transitions between two functionally equivalent states—that is, $A_1{\cdot}A_2' \rightleftarrows A_2{\cdot}A_1'$—and no translocations occur. (The two functionally equivalent subunits, A and A′, each contain a complex of a tRNA molecule, its codon, and a corresponding ribosomal site. The subscripts, 1 and 2, designate the two possible states of a subunit.) The simplest specific version of this allosteric mechanism is illustrated in Fig. 2.

In the figure, S and S′ signify the functionally equivalent ribosomal sites, each containing one tRNA molecule bound to its codon. The sites are situated so that the two tRNAs can interact to form the translation complex of Fig. 1. Fig. 2*A* (the $A_1{\cdot}A_2'$ state) depicts a point in the middle of a translation, for example, with $tRNA_3$ (peptidyl, *FH* conformation) in the S site and the next tRNA, $tRNA_4$ (aminoacyl, *hf* conformation) in the S′ site. As a consequence of peptidyl transfer, $tRNA_4$ will (for reasons not specified) undergo an *hf*→*FH* transition; see Fig. 2*B*. $tRNA_4$ does not leave the S′ site in the process, and its anticodon stalk is here pictured to remain completely stationary while the duplex composed of codon No. 4 and its anticodon undergoes a "flip" (as a single unit)*. The "flip" necessarily breaks the original *SDS* helical segment and displaces codon No. 3 from the axis of the translation complex, causing $tRNA_3$ to vacate site S as a result. The same event, moreover, pulls the mRNA so that codon No. 5 now enters the S site. Fig. 2*C*, where $tRNA_5$ (aminoacyl, *hf* conformation) has also entered the S site to pair with codon No. 5, then corresponds to the $A_2{\cdot}A_1'$ state. At the next peptidyl transfer event $tRNA_5$, without moving its stalk, shifts into the *FH* conformation, displacing both $tRNA_4$ and its codon from site S′, and bringing codon No. 6 into that site (Fig. 2*D*). When $tRNA_6$ (aminoacyl, *hf* conformation) enters site S′, the cycle is completed (that is, the translation complex again has the $A_1{\cdot}A_2'$ form of Fig. 2*A*).

In terms of these numberings, even numbered tRNAs are "decoded" in one site, odd numbered ones in the other. This allosteric transition mechanism pulls the mRNA tape through the ribosome in a manner reminiscent of a double reciprocating ratchet. Because conformational changes in the tRNA molecule are primarily responsible for the mechanics involved, the main roles for the ribosome may be in providing the static sites, S and S′, in catalysing the actual peptidyl transfer, and perhaps in assisting somehow the *hf*→*FH* transitions. It should be stressed that this version is a "first approximation" model, and that one can anticipate refinements and/or modifications of non-essential features, if the basic mechanics prove to be essentially correct. For example, entry and/or exit sites, preceding or succeeding (respectively) the actual translation complex might be contemplated for any of a number of reasons.

Symmetry of Ribosomal Sites

Most of the arguments that gave rise to and support the A-site–P-site theory come from experiments demonstrating properties unique to one or the other of the ribosomal subunits. For example, codon-specific tRNA binding is a property of the 30S subunit, while the 50S subunit seems to hold the tRNA carrying the nascent peptide and to possess factors involved in peptidyl transfer[3,6,9]. The essence of the A site seems to be in the 30S subunit, while the P site resides in its 50S counterpart. Were any site to comprise parts from both the 30S and the 50S subunits, however, results such as these might well be expected. (There is no *a priori* reason for an mRNA or a tRNA molecule to react in the same fashion with both parts of any given site; nor is it necessary for the aminoacylated form of tRNA to react with any site—or part thereof—in the same way that its peptidylated counterpart does.) Evidence such as I have discussed therefore can neither prove the A-site–P-site theory, nor rule out the allosteric model alternative.

I do not intend to discuss in detail the relationship of this model to the overall tertiary structure of tRNA or to the structure of the ribosome. A few obvious points must be made, however. It is reasonable to expect each of the postulated S sites to comprise parts from both the 50S and the 30S ribosomes, so that the axis of two-fold rotational symmetry (that is, the dyad described in the caption of Fig. 1) passes through and applies to both ribosomal subunits. Evidence at present ostensibly does not favour such a symmetrical ribosome; for example, neither ribosomal subunit contains more than one copy of any given type of protein[18]. It must be realized, however, that all we require here is functional (not primary structural) symmetry, that a pseudo-symmetry may be all that is actually needed, and that symmetry considerations could apply only to a portion of each ribosomal subunit in any case.

On the other hand, the 50S particle has always seemed likely to be an "evolutionary dimer" by its overall molecular weight, the molecular weight of its RNA, and the number of protein molecules it contains (all of which are double their counterparts in the 30S particle)[18]. More recently it has been found that all of the (T1 RNase) oligonucleotide segments in the 23S rRNA that contain post-transcriptionally modified bases are present in two copies per molecule, as are some segments of this type from the 16S rRNA—consistent with, and suggestive of, the required symmetry[19]. Certain nucleic acid hybridization measurements also suggest some sort of two-fold symmetry to the primary structure of the 23S rRNA[20].

---

* This "flip" can be simulated using a beer can as follows: the right hand grasps the upright can. The fingers, simulating the position of the codon, should be not quite horizontal but tilted slightly upward. The hand then rotates as a right-handed screw, the wrist simultaneously turning so that the can's axis becomes horizontal with its "top" facing to the left. Then the hand rotates in the reverse direction, the wrist now turning so that the can's axis is once again vertical, but this time with the can inverted. The two groups of bases underlying the codon–anticodon unit (that is, Nos. 11 and 12 on the one strand, Nos. 6 and 7 on the other) each rotate approximately clockwise (viewed from the anticodon stalk) during the "flip", causing the pyrimidine group (Nos. 11 and 12) to swing out of, the other group (Nos. 6 and 7) to swing into, helical pitch.

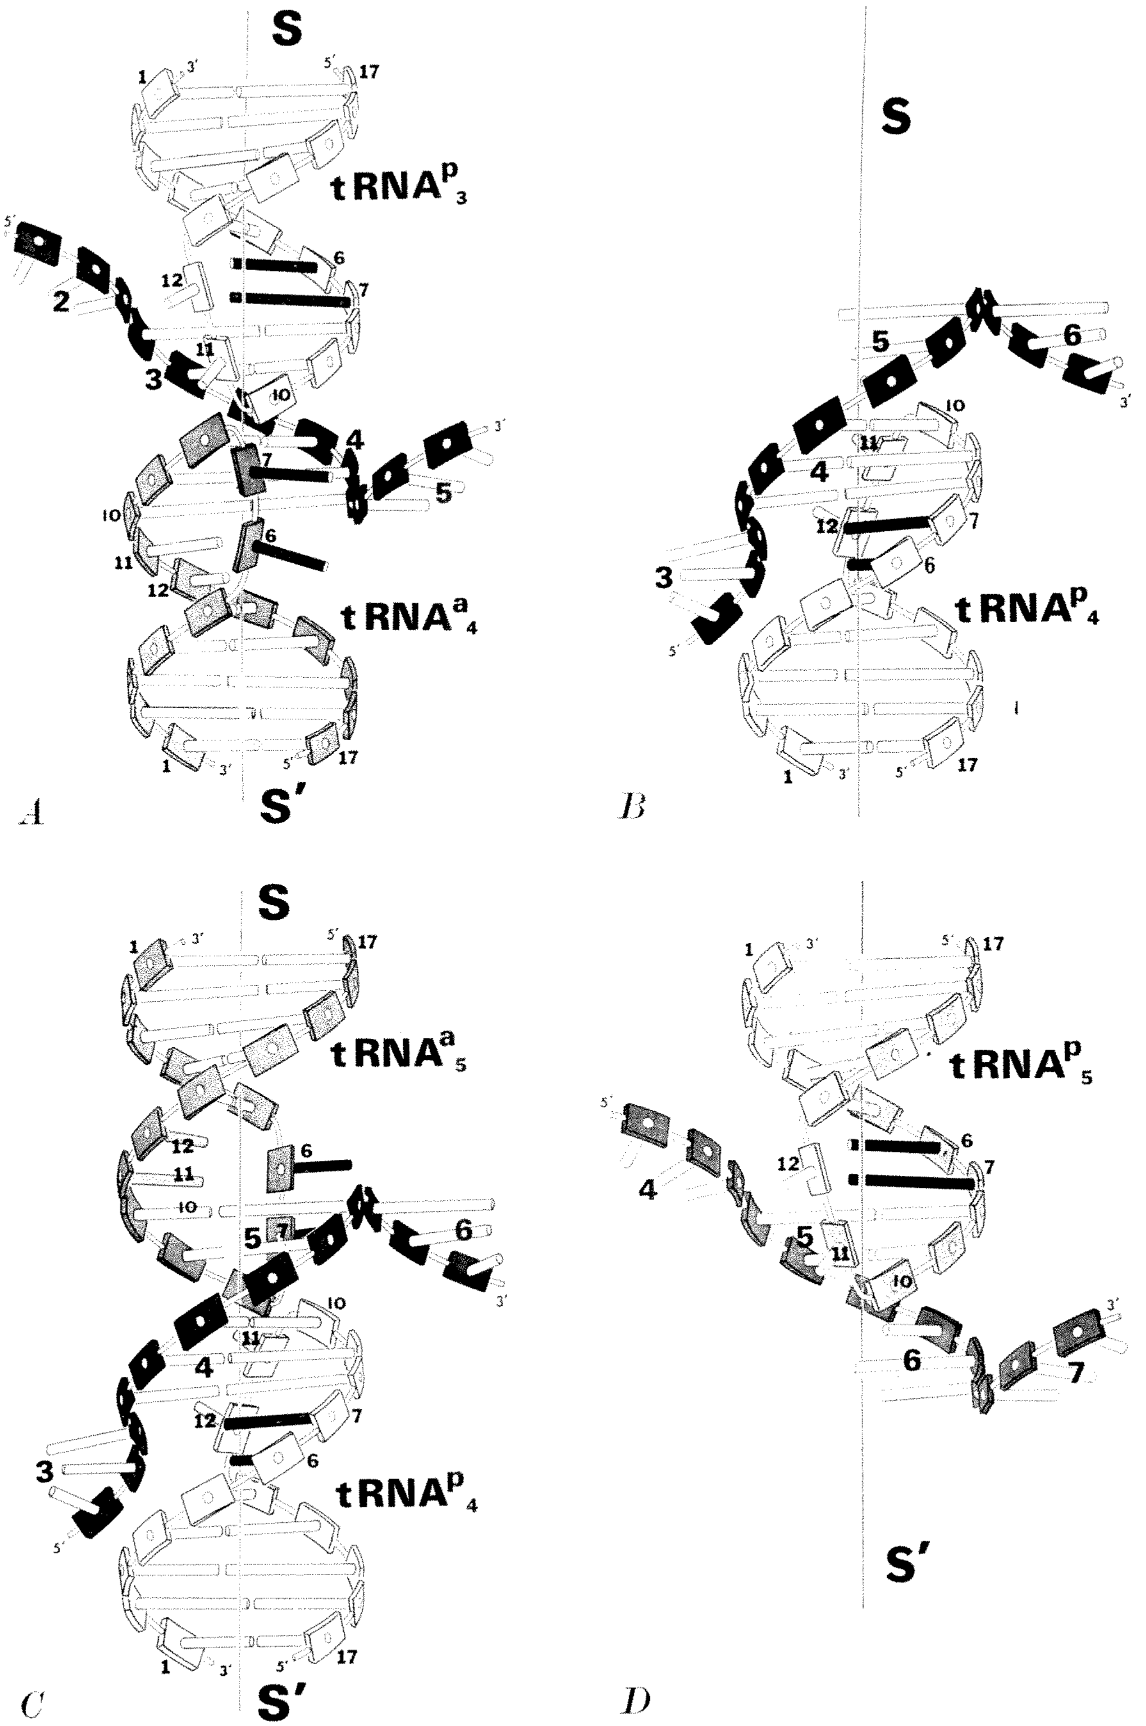

Fig. 2. The molecular mechanics of translation. *A*, The basic translation complex of Fig. 1, with the peptidyl tRNA (superscript "p"), in *FH* conformation, in the S (upper) site and the incoming aminoacyl tRNA (superscript "a"), in *hf* conformation, in the S′ (lower) site. Subscripts designate the time order of appearance of tRNAs in translation. Large numbers designate codons in their order of occurrence in mRNA; other numbering is as in Fig. 1. The $hf \rightarrow FH$ conformational transitions and consequent mRNA movement, occurring in *B*, *C* and *D*, are explained in the text.

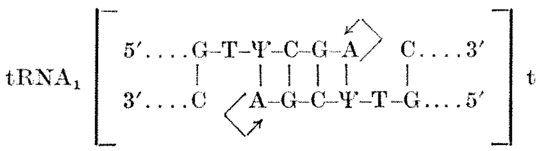
Tertiary Structure of tRNA

Although the multiple conformations of a tRNA molecule demanded by the present model have yet to be identified, it should be noted: (*a*) that "denatured" (as opposed to "normal") forms of various tRNAs have been reported, and (*b*) that uncharged tRNAs exist in what appears to be the *hf* conformation[21-23].

In any simple form this model requires that the overall structures of the peptidyl and the aminoacyl tRNAs (in a translation complex) be such that the incoming amino-acid and the nascent peptide are brought into approximate juxtaposition. If the gross tertiary structures of these two tRNAs are taken to be approximately the same, then the two CCA ends should meet in the vicinity of the symmetry axis. Of the models so far proposed for tRNA tertiary structure, only two seem to fulfil this requirement (the model attributed to Doctor *et al.* and that proposed by Melcher[24-26]).

The model discussed here also suggests that tRNA may pass through a set of functionally interrelated configurations during translation, of which the *hf*→*FH* is only a part. In view of the variety of tRNA tertiary structures that seem to be sterically feasible, larger changes—for example, rotation of an arm relative to the rest of the structure—might be considered[26]. Particular attention should be given to the "TΨC" arm, common to all tRNAs. In its general form it is identical to any anticodon arm, immediately suggesting the possibility of *hf*↔*FH* transitions. It should further be noted that in the *hf* conformation one such common arm can generally form a coaxial double helical segment with another common arm, a structure that includes the following symmetrical base paired segment:



The allosteric translation model is too crudely delineated at present to warrant a detailed discussion of the exact roles it would assign to the various initiation, termination, binding and so on, factors required for protein synthesis[2,10,11,27]. In that the present model (in any simple form) specifically does not utilize "translocations" (moving of the tRNA-codon complex from one translation site to another), however, we must briefly consider the so-called "G", or "translocase", factor customarily assigned the role herein proscribed[2]. Clearly, all its reported characteristics[2] are consistent with a role in which "translocase" facilitates transitions—*hf*→*FH* or others.

Although it has obvious relevance to cellular dynamics, I feel the ultimate value of the model proposed herein will lie in its evolutionary implications—that is, it places the burden for translation in any primitive system on the tRNA–mRNA interaction, and so allows the "protoribosome", at least in principle, to be a rather simple and static entity. Detailed evolutionary implications of this model are presented elsewhere (my work, in preparation).

I thank Stanley Jones for preparation of the figures used herein, and am grateful for discussion of this model with Dr F. H. C. Crick and other members of the Cambridge MRC unit and with R. Kilkson.

Control of Translation by T4 Phage: Altered Binding of Disfavoured Messengers

by
SHYAM K. DUBE
PHILIP S. RUDLAND
MRC Laboratory of Molecular Biology,
Hills Road, Cambridge CB2 2QH

A messenger selection process operates in infected cell extracts at the level of polypeptide chain initiation; and the agent responsible is present chiefly in the factor fraction of the ribosome.

After infection of *Escherichia coli* by T-even phages, host protein synthesis is switched off[1-4], although the overall rate of protein synthesis continues almost unabated[5,6]. This change may be mediated at the transcriptional level for T4 by synthesis of a new sigma factor[7,8] which alters the initiation specificity of the host RNA polymerase, thereby allowing preferential synthesis of phage-specific RNA. Whether there is control at the translational level is less well understood. From the findings that RNA phages are unable to replicate in cells superinfected with T4 (refs. 9–11), Hattman and Hofschneider[10] have suggested that T4 exerts its control by interfering with the capacity of viral RNA to function as messenger. More recently, Hsu and Weiss[12] and Schedl, Singer and Conway[13] have reported that a factor from T4-infected cells induces an alteration in host ribosomes which restricts the translation of host[12] and other RNAs unrelated to T4 (refs. 12 and 13) but permits normal translation of

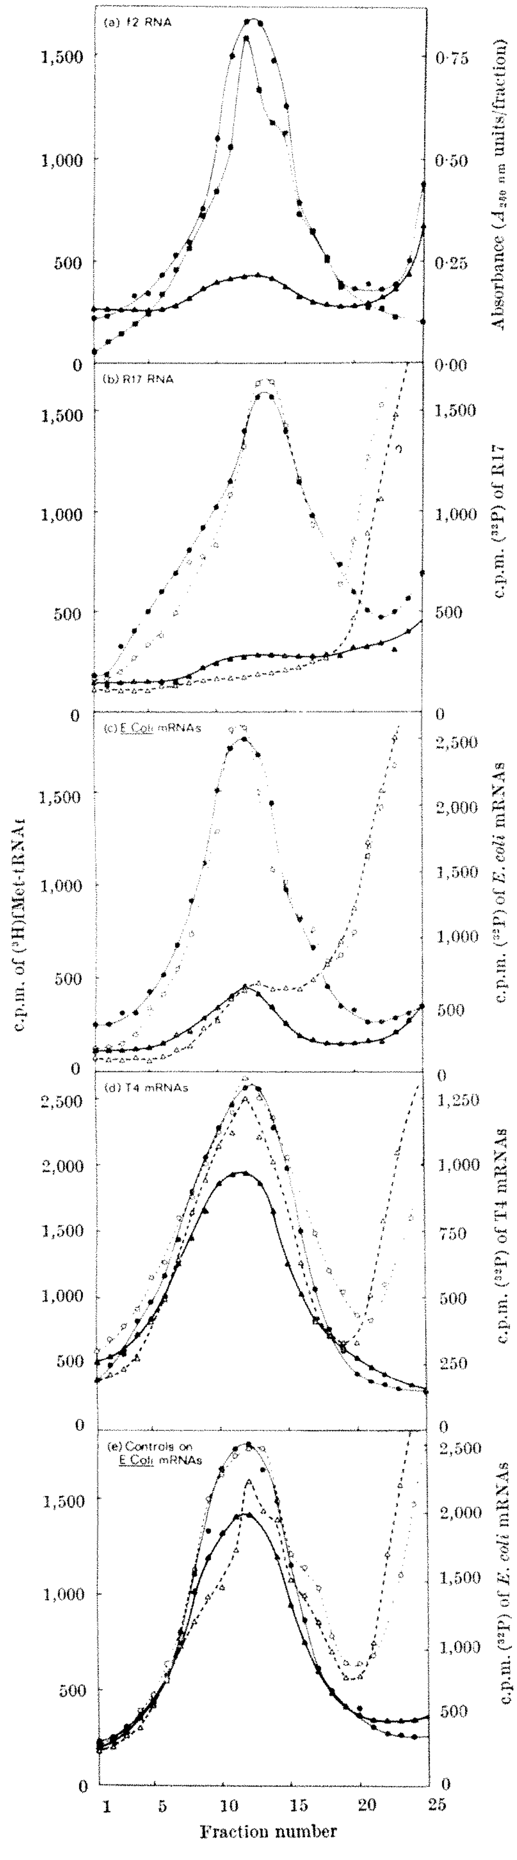

Fig. 1. Ribosomal binding on sucrose density gradients. For *a–d* binding of fMet-tRNA$_f$ and mRNAs was followed on gradients. Absorbance ($A_{260\ nm}$ units/fraction), ■—■; c.p.m. of ^{3}H-fMet-tRNA$_f$ with *E. coli* factors, ●—● or T4 factors, ▲—▲; and c.p.m. of ^{32}P-labelled messenger RNAs with *E. coli* factors, ○ - - - ○ or T4 factors, △ - - - △. For *e*, *E. coli* mRNAs were incubated with either *E. coli* factors (●, ○) or T4 factors (▲, △) in the complete reaction; the RNA was extracted and reincubated with the complete *E. coli* system before following the binding on sucrose density gradients. ^{32}P-labelled messenger RNAs from *E. coli* MRE600 and T4 infected cells were prepared at 37° C in 100 ml. cultures of 0·1 M Tris-HCl (*p*H 7·4), 0·02 M KCl; 0·09 M NaCl; 0·02 M NH$_4$Cl; 0·001 M MgSO$_4$; 0·4 per cent glucose; vitamin free casamino-acids and Difco bacto-peptone, both 2 g/l. (medium II). The exponentially growing cells were pulsed for 7 min with radioactive isotope, while the T4 infected cells were labelled from 5 until 12 min after infection. Isolation was as in Table 1, and the fractions corresponding to a 12S to 18S region were pooled for the messenger preparations. ^{32}P-labelled R17 RNA was a gift from Dr J. Nichols and Mr P. Jeppesen, isolated according to the method of Anderson *et al.*[31]. ^{32}P-labelled and non-radioactive messenger preparations were mixed in the following experiments. The reaction mixtures (50 µl.) contained the same buffer, GTP, and salt solutions as in Table 1, with 210 pmoles of *E coli* ribosomes, 100,100 c.p.m. of ^{3}H-labelled fMet-tRNA$_f$ (2,050 c.p.m. per pmole) and either 190 µg of *E. coli* factors (●—●), or 210 µg of factors from T4 infected cells (▲—▲). The messengers used were: *a*, f2 RNA, 3·3 $A_{260\ nm}$ units; *b*, R17 RNA, 2·0 units and 100,000 c.p.m. ^{32}P; *c*, host mRNAs, 3·1 units and 401,000 c.p.m.; *d*, T4 mRNAs, 2·6 units and 140,000 c.p.m. The procedure was as for Table 1, except that at the end of the incubation period the reactants were chilled on ice, 40 µl. of each mixture layered on a 5 ml. 5 to 20 per cent sucrose density gradient in 0·05 M Tris–HCl (*p*H 7·4); 0·05 M NH$_4$Cl; 0·005 M magnesium acetate (buffer B) and sedimented at 40,000 r.p.m. for 110 min in a Beckman model 'L' centrifuge with an 'SW50' rotor[13]. Two drop fractions (approximately 0·13 ml.) were collected from the bottom of the gradient directly into 2 ml. of 15 per cent trichloroacetic acid (TCA), and the precipitate was retained on nitrocellulose filters which were washed with 3 × 2 ml. addition of 5 per cent TCA, dried, and counted in a liquid scintillation spectrometer. "Spill-over" of ^{32}P c.p.m. into the ^{3}H channel of the spectrometer was less than 2 per cent. The c.p.m. of ^{3}H-labelled fMet-tRNA$_f$ (———, with closed symbols) and ^{32}P-labelled mRNAs (- - -, with open symbols) could be followed as a function of fraction number, whilst in *a* the total $A_{260\ nm}$ units of each fraction from the complete reaction mixture was recorded (■—■). For *e* host mRNAs were incubated in the same complete binding reaction as for *c* with either factors from T4 infected cells (▲—▲) or factors from host cells (●—●). On completion of the reaction, the mixtures were deproteinized by extraction with phenol and 2 per cent sodium dodecyl sulphate, and the RNA was precipitated with ethanol. 386,000 c.p.m. of this ^{32}P-RNA was then reincubated in the normal binding reaction with *E. coli* factors and ribosomes in both mixtures and the resultant ribosomal binding followed on sucrose density gradients.

T4 messenger RNAs[12]. (W. Salser and R. F. Gesteland, quoted in ref. 10, have also observed restricted translation of R17 RNA.)

We now demonstrate by binding experiments that a messenger selection process operates in infected cell extracts at the level of polypeptide chain initiation. The agent(s) responsible for this effect is present chiefly in the "factor"* fraction of the ribosome, which also contains several new proteins made after infection. The following article[14] shows that this "factor" interferes unequally with the initiation of protein synthesis at the three known genes of phage R17.

T4 Factors preclude Host mRNA Binding

Because the rate determining step in protein synthesis may be the formation of the initiation complex between fMet-tRNA$_f$, ribosomes, initiation factors, GTP and messengers[15–19], this is a probable point for translational control. We therefore tested the ability of host and T4 messengers to form initiation complexes with salt-washed ribosomes and factors, derived both from normal and from T4 infected cells. As messengers we also used the R17 and f2 RNAs. Because T4 excludes R17 or f2 phages, if ribosomes from infected cells display altered specificity for host mRNAs they may also do so for the viral RNAs.

Table 1 illustrates a striking difference in the ability of the RNAs to function as messengers as judged by the ribosomal binding of fMet-tRNA$_f$ on nitrocellulose filters[20]. T4 mRNAs are capable of forming a strong complex with all permutations of salt-washed ribosomes and factors, but R17, f2 and host messenger RNAs are unable to do so with either T4 washed ribosomes and T4 factors or *E. coli* ribosomes and T4 factors. Thus the complete ribosome from T4 infected cells is unable to form a stable initiation complex with host mRNAs, and this effect is localized largely in the factor fraction of

* The term "factor" denotes those proteins obtained from the supernatant after sedimenting ribosomes through a 2 M NH$_4$Cl buffer, and includes the known initiation factors. The prefix host or T4 designates whether the component has been isolated from *E. coli* or T4 infected *E. coli* cells.

Table 1. NITROCELLULOSE FILTER BINDING OF fMet-tRNA$_f$ TO RIBOSOMES WITH DIFFERENT MESSENGERS

E. coli ribosomes	T4 ribosomes	*E. coli* factors	T4 factors	*E. coli* mRNAs	T4 mRNAs	R17 RNA	f2 RNA	ApUpG
+	−	−	−	0·6	0·4	0·4	0·6	0·5
+	−	+	−	4·8	3·8	5·4	4·4	5·3
+	−	−	+	1·0	3·8	0·7	1·0	5·2
−	+	−	−	0·5	0·4	0·1	0·3	0·4
−	+	+	−	3·9	4·5	4·7	4·0	5·0
−	+	−	+	0·8	5·3	0·3	0·5	5·6

T4 phage infected cells were prepared as follows: 30 l. of *E. coli* MRE600 cells were grown at 37° C in 0·02 M Na_2HPO_4; 0·011 M KH_2PO_4; 0·047 M NaCl; 0·009 M NH_4Cl; 0·001 M $MgSO_4$; 0·4 per cent glucose Difco bactotryptone, 5 g/l. (medium I) to a density of 3×10^8 per ml., infected with T4 phage at a multiplicity of 10× phage to bacteria, superinfected at a multiplicity of 4× 7 min later, and finally collected 13 min after the first infection. Cell survival after 2 min was less than 0·5 per cent, and approximately 40 g wet weight of cells was collected by centrifugation and stored frozen. Uninfected *E. coli* MRE600 cells were obtained from the Microbiological Research Establishment, Porton Down, Salisbury, Wiltshire. The ^{14}C-labelled pure fMet-tRNA$_f$ (specific activity 217), ApUpG, crude initiation factor preparation from a 2 M NH_4Cl buffer washing of ribosomes, and the high salt-washed ribosomes themselves were prepared as previously reported[27], except that the ribosomes were sedimented twice through the 2 M NH_4Cl buffer. All ribosomal components were aliquoted, and stored in liquid nitrogen before use. R17 RNA was prepared according to Gesteland and Boedtker[28]; f2 RNA was a gift from Mr M. Hooper prepared after the method of Webster *et al.*[29]. For the messenger RNAs from host and T4 infected cells the *E. coli* MRE600 cells were grown to a density of 3×10^8 per ml., fast cooled, collected by centrifugation, and immediately lysed with lysosyme—EDTA and 'Brij 35' (ref. 30). The RNA was deproteinized by phenol extraction, concentrated by ethanol precipitation and fractionated on sucrose density gradients, where fractions corresponding to maximum activity for initiation complex formation were pooled (manuscript in preparation) (approximately 12S to 18S for both T4 and host mRNAs). The initiation complex formation with these messengers depended on the presence of all components (that is, fMet-tRNA$_f$, ribosomes, GTP, and factors). Each reaction mixture (50 μl.) contained 0·1 M Tris-HCl (*p*H 7·2); 0·055 M NH_4Cl; 0·0055 M $MgCl_2$; 0·0002 M GTP; 11·4 pmoles fMet-tRNA$_f$; 34 pmoles of high salt-washed 70S ribosomes from either host or T4 infected cells, and 42 μg of crude factors from host or 40 μg from T4 infected cells where indicated. The messengers used were one of the following ($A_{260\ nm}$ units): *E. coli* mRNAs (1·2); T4 mRNAs (1·1); R17 RNA (1·4); f2 RNA (1·1); or ApUpG (0·12). All messengers were preincubated for 2 min at 37° C in 0·0001 M Na_2EDTA solution before addition of the remaining reactants, and incubated for a further 10 min at that temperature. The reaction was terminated by dilution sixty-fold with ice-cold 0·1 M Tris-HCl (*p*H 7·2); 0·05 M NH_4Cl; 0·005 M $MgCl_2$ (buffer A) followed by filtration through nitrocellulose filters. These filters were subsequently washed three times with 3 ml. of buffer A, dried, counted in a liquid scintillation spectrometer, and the pmoles of ^{14}C-fMet-tRNA$_f$ retained on the filter recorded.

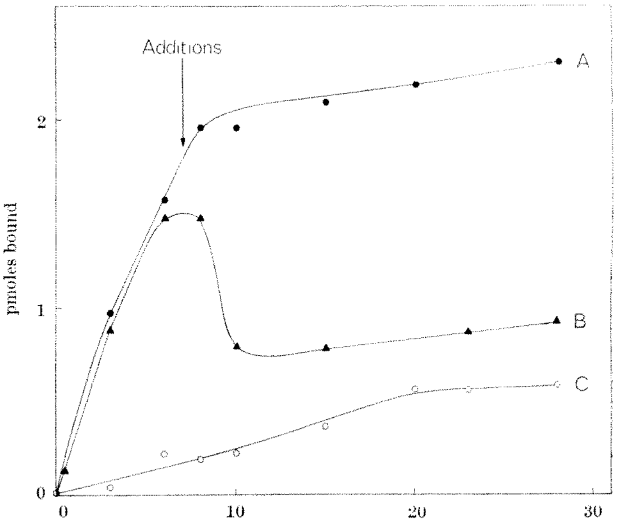

Fig. 2. Competition of host and T4 factors for initiation complex formation. *A*: host ribosomes + host factors; addition host factors. *B*: host ribosomes + host factors; addition T4 factors. *C*: host ribosomes + T4 factors; addition host factors. Reaction mixtures (500 μl.) contained the same buffer, GTP and salt solutions as in Table 1 with 340 pmoles *E. coli* ribosomes, 110 pmoles of ^{14}C-fMet-tRNA$_f$, 12·3 $A_{260\ nm}$ units of *E. coli* mRNAs, and either 420 μg of factors from host cells (*A* and *B*) or 400 μg from T4 infected cells (*C*). The reactants were incubated as for Table 1 at 37° C, but 25 μl. aliquots were withdrawn at the stated times and diluted into 3 ml. of buffer A, whereupon they were filtered and counted in the normal manner. After 7 min 420 μg of *E. coli* factors was added to *A* and *C*; and 400 μg of T4 factors to *B*. The subsequent binding of fMet-tRNA$_f$ to ribosomes (in pmoles) was followed as a function of time. Results from control experiments containing no factors have been subtracted from the total binding of fMet-tRNA$_f$.

the ribosome. While for both T4 and host mRNAs these are average results from a spectrum of messengers isolated between 12S and 18S on a sucrose density gradient, the same results were also obtained when fractions across this gradient were assayed.

Similar conclusions have been drawn from experiments in which the initiation complex itself was isolated on sucrose density gradients[21]. Both ^{32}P-labelled and non-radioactive messengers were isolated and combined, so that the binding capabilities of fMet-tRNA$_f$ and messenger RNAs could be investigated independently (Fig. 1). There is a small residual ribosomal binding of both fMet-tRNA$_f$ and R17 or host messengers with T4 factors and *E. coli* washed ribosomes, which cannot be abolished even with washed ribosomes and factors from T4 infected cells. This residual ribosomal binding with R17 RNA is the subject of the following communication[14].

Because we detected some nucleolytic breakdown of the R17 RNA with T4 factors and ribosomes, as a control we repeated the normal ribosomal binding reaction with the complete system containing T4 derived ribosomal components, then reisolated the RNA, and used this in a subsequent binding reaction with host cell ribosomal components. There was virtually no change in the amount of fMet-tRNA$_f$ or mRNA bound to the ribosome compared with a control system starting with *E. coli* ribosomal components in the first reaction mixture, both for the host mRNAs (Fig. 1*e*) and R17 RNA. Consequently the extra nucleolytic activity is not the primary cause for the failure of T4 factors to support a stable initiation complex with host messengers.

The relationship of the messenger-discriminating agent associated with ribosomes from T4 infected cells to existing ribosomal components is not clear. As shown in Table 2, all messengers required a component additional to the initiation factor proteins F1 and F2a, whereas the initator codon AUG did not. This protein, which assists natural mRNA binding, has been termed F3 (ref. 22) or B (ref. 23). Exchange, modification or destruction of the host's F3 molecules on phage infection might result in preferential selection of phage mRNAs over those of the host.

Table 2 also shows that the inability of F1 and F2a to support a strong initiation complex with natural messengers is maintained even after re-extraction of the RNA from a reaction mixture containing ribosomal components from T4 infected cells and host ribosomes. Thus the nuclease activity of these components was not exposing additional initiator codons (that is, AUG or GUG) which could serve as fresh binding sites.

Factor proteins from T4 infected cells compete with those from normal cells and destroy the initiation com-

Table 2. RIBOSOMAL BINDING OF mRNAs WITH INITIATION FACTORS F1 AND F2a

Host factors	T4 factors	F1 + F2a factors	ApUpG	R17 RNA		T4 mRNAs		Host mRNAs		Host mRNAs*	
			[^{3}H]	[^{3}H]	[^{32}P]	[^{3}H]	[^{32}P]	[^{3}H]	[^{32}P]	[^{3}H]	[^{32}P]
−	−	−	1,500	300	200	1,300	800	700	1,500	−	−
+	−	−	14,200	11,000	8,100	15,800	8,800	12,100	12,700	−	−
−	+	−	14,600	500	300	13,300	7,900	1,600	1,300	−	−
−	−	+	14,100	1,100	300	1,100	600	500	1,600	700	1,000

* Host mRNAs extracted from an incubation mix containing T4 factors.
[^{3}H] refers to ^{3}H-fMet-tRNA$_f$, and [^{32}P] to ^{32}P-mRNA.

Initiation factors F1 and F2 of Stanley *et al.*[32] were further purified by fractional precipitation with $(NH_4)_2SO_4$ and passage over a phosphocellulose column for F1[33], or chromatography on successive columns of hydroxyapatite and 'DEAE-Sephadex' for F2 (unpublished results of P. S. R.). The original F2 fraction was resolved into two components, termed F2a and F2b in order of elution from the initial DEAE-cellulose column. Reaction mixtures (50 μl.) and procedure are as for Fig. 2 except that either no factors, *E. coli* factors, or T4 factors were added in the same amounts as used previously. In addition 4 μg of F1 and 80 μg of F2a were added as indicated in place of the unfractionated factors. Messengers used were in the same concentrations as for Fig. 2 and also 0·14 $A_{260\ nm}$ units of ApUpG were included. The total radioactivity in the 70S region of the gradient was tabulated for both ^{3}H-fMet-tRNA$_f$ and ^{32}P-mRNA. In the final column, experiment (*e*) from Fig. 1 was repeated by incubating host mRNAs with T4 factors and *E. coli* ribosomes, but the RNA obtained after phenol extraction was reincubated in the complete reaction mixture with F1 and F2a at the same concentrations as above, in place of the unfractionated factors.

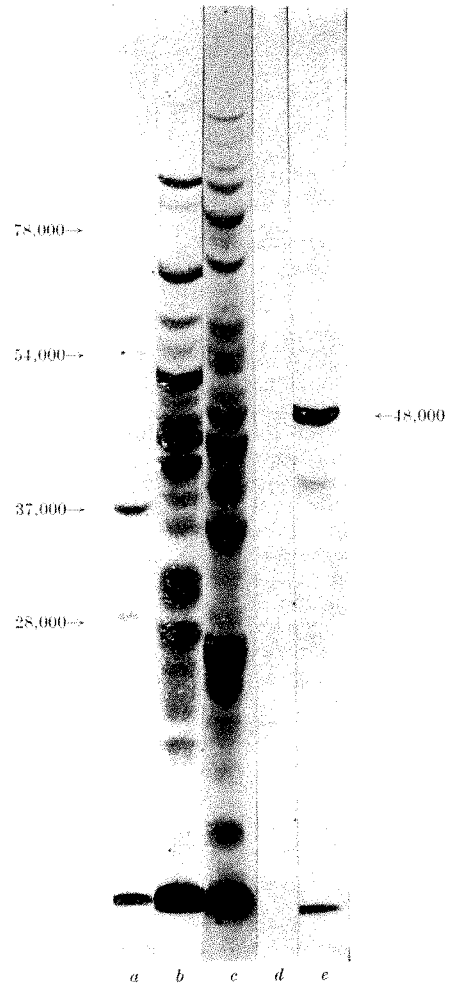

Fig. 3. Autoradiograms of polyacrylamide gels. Disc electrophoresis[24] in 10 per cent polyacrylamide gels containing 0·1 per cent sodium dodecyl sulphate[25], as well as the preparation of autoradiograms[26], was carried out as described by U. Laemmli and J. Maizel (manuscript in preparation). *a*, Factor fraction from T4 infected cells labelled with ^{35}S from 2 to 7 min after infection; *b*, factor fraction from uninfected cells labelled with ^{35}S for 5 min; *c*, 100,000*g* ribosome free supernatant from T4 infected cells pulsed from 2 to 7 min; *d* and *e*, proteins from 2 M NH_4Cl washed ribosomes from T4 infected cells, pulse time 5 to 10 min after infection *d* and 10 to 15 min after infection *e*. In addition to the major protein bands there is some general background. The molecular weights were determined with reference to the mobilities of marker proteins, and are accurate to within 10 per cent. *E. coli* MRE600 cells were grown at 37° C in 100 ml. of low sulphate medium containing 0·02 M Na_2HPO_4; 0·011 M KH_2PO_4; 0·047 M NaCl; 0·009 M NH_4Cl; 0·00095 M $MgCl_2$; 0·00005 M $MgSO_4$; and 0·4 per cent glucose. At a cell density of 3×10^8 per ml., cells were infected with T4 phage as described in Table 1 and pulsed for 5 min with $^{35}SO_4$ at (*a*) 2, (*c*) 5, (*d*) 10 min after infection. A preparation of ^{35}S-labelled uninfected cells (*b*), pulsed for 5 min in the same conditions, was also made. Isolation of ribosomes and factors was as described in Table 1, except that ribosomes were first sedimented through a buffer containing 0·001 M puromycin to remove nascent polypeptide chains, before sedimenting through the 2 M NH_4Cl buffer.

plex formed with the host mRNAs almost completely. Consequently, equal amounts of host factors are unable to restore the ribosomal binding ability in the reaction mixture containing *E. coli* washed ribosomes and factors from T4 cells, as measured by the ribosomal binding of fMet-$tRNA_f$ on nitrocellulose filters (Fig. 2). Partial restoration of the initiation complex on sucrose density gradients was observed, however, on addition of a five-fold excess of host factors, possibly reflecting a higher affinity of T4 factors for the ribosome.

New Proteins in T4 Factor Fraction

Finally, we pulse-labelled the host cells with radioactive sulphate following T4 infection, and fractionated the proteins obtained from them on polyacrylamide gels. Several new proteins were found in the ribosomal factor fraction and a major one associated with salt washed ribosomes (Fig. 3). The former could be detected within 2 min of phage infection and were still present 15 min later, while the latter was not apparent until 10 min after infection. None of the new proteins exhibits the same mobility as any of the host factor proteins or of the 100,000*g* supernatant proteins synthesized after T4 infection. Nevertheless, the possibility that these new proteins arose from modifications of existing ones cannot be discounted. (Smith and Haselkorn quoted in ref. 12 have also found new proteins associated with ribosomes after T4 infection.)

The relevance of these proteins to the functional alteration of ribosomes is not yet clear, but it may be significant that new proteins in the factor fraction can be detected within the time period of termination of host protein synthesis. In addition, the finding that T4 factors hinder the *in vitro* initiation complex formation of f2 and R17 as well as of host mRNAs may explain in part observations *in vivo* on the restriction of viral (R17 and f2) and host protein synthesis after T4 phage infection.

In conclusion, the results demonstrate a possible mechanism for translational control of gene expression in the infected cell, in that selection for a class of messengers is imposed after infection. This selection operates at the level of polypeptide chain initiation, and the agent(s) primarily responsible occur(s) in the ribosomal factor fraction. It would not be surprising if more elaborate mechanisms of this general nature occur in higher organisms.

We thank Dr W. McClain for help and advice concerning T4 bacteriophage, Mr W. A. Whybrow for assistance in isolation of the T4 infected cells, Dr F. H. C. Crick and Dr J. Fresco for criticism of the manuscript and Dr B. F. C. Clark for encouragement. During this work P. S. R. was supported by a scholarship from the Salters' Institute of Industrial Chemistry.

Control of Translation by T4 Phage: Altered Ribosome Binding at R17 Initiation Sites

by

JOAN ARGETSINGER STEITZ
SHYAM K. DUBE
PHILIP S. RUDLAND

MRC Laboratory of Molecular Biology,
Hills Road, Cambridge CB2 2QH

After infection of *E. coli* by T4 phage, ribosomes lose their ability to bind efficiently to the coat and synthetase initiation sites of R17 RNA. This change lies in the initiator factor fraction.

THE preceding article[1] shows that ribosomes isolated from *Escherichia coli* infected with phage T4 interact only weakly with phage R17 RNA to form polypeptide chain initiation complexes *in vitro*. To examine the messenger sites recognized by these ribosomes, we have made use of the fact that ribosomes from uninfected *E. coli* attach to the initiator regions of all three genes in the R17 RNA. Ribosomes from T4 infected cells, by contrast, discriminate against the coat protein and synthetase initiation sites and bind appreciably only to the beginning of the A protein cistron. This property, like the agent affecting the levels of initiation complex formation described in the preceding article, resides in the initiation factor preparation.

If radioactive R17 RNA is incubated with ribosomes from *E. coli* in the presence of GTP and formylmethionyl tRNA, regions at the beginning of its three cistrons are bound and protected from pancreatic ribonuclease digestion[2]. A sequence of approximately thirty-five nucleotides at each of these sites has been elucidated. When isolated from the 70S ribosomal fraction of a sucrose gradient and subjected to "fingerprint" analysis, mixtures of the three R17 initiator fragments yield several large T_1 oligonucleotides (Fig. 1*a*). Because each of these (with the exception of UUUG) arises specifically from one or another of the three R17 binding sites, a T_1 ribonuclease fingerprint provides a direct assay for differential ribosome recognition of the initiator regions in a messenger RNA. The relative yields of the three sites can be estimated not only by inspection, but determined

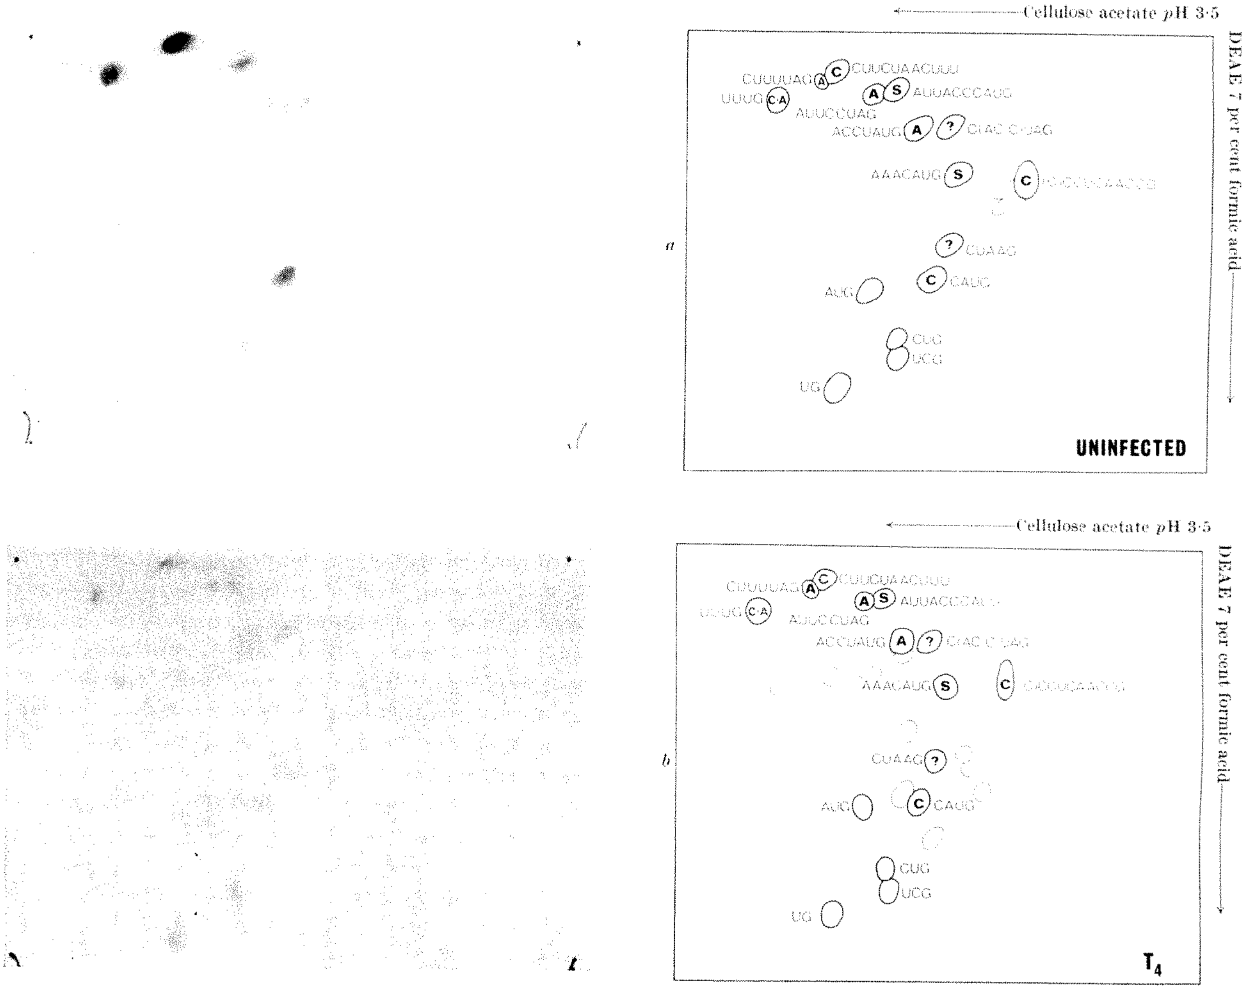

Fig. 1. Ribonuclease T1 fingerprints of R17 initiator regions bound by low-salt-washed ribosomes from uninfected (*a*) and from T4-infected (*b*) cells. The fingerprints shown are those obtained in experiment 1 of Table 2, where the details of the binding reactions and of the preparation of the ^{32}P-labelled RNA fragments for fingerprinting are given. Fingerprint *a* was exposed for 36 h whereas fingerprint *b* was exposed for 5 days. The illustrations exemplify the type of fingerprints from which oligonucleotide spots were cut and counted to provide the data in Tables 1–3. The diagrams of the fingerprints show the sequences of those oligonucleotides routinely analysed and their origins: A, a protein initiation site; C, coat protein site; S, synthetase site. The two oligonucleotides marked "?" have been frequently detected (in varying amounts) in T_1 ribonuclease fingerprints of R17 binding sites, but they have never been found linked to any of the three established sequences.

quantitatively by counting the radioactivity in the appropriate oligonucleotide spots (which can subsequently be positively identified by analysis of their pancreatic ribonuclease digestion products).

The fingerprint in Fig. 1*a* and the data in Table 1 (experiment 1, column *a*) give the results of one binding assay in which the A, coat and synthetase initiation sites were protected in molar ratios of 1:7·3:1·6 by ribosomes washed at low salt concentration (which retain their initiation factors) from uninfected *E. coli*. The relative amounts of the three sites vary from experiment to experiment depending on the integrity of the ^{32}P-labelled RNA added to the binding reaction; more degraded R17 RNA results in lower yields of the coat site relative to the A and synthetase sites[2], as in experiment 2, Table 1, column *a*. In parallel binding reactions performed with the same R17 RNA and ribosome preparations, however, a variability of only about 30 per cent in the ratios of the three sites is observed (although the absolute number of counts obtained in duplicate fingerprints may be quite different because of differential losses during the preparation of samples for fingerprinting).

Differential Recognition of R17 RNA Binding Sites

A T$_1$ ribonuclease fingerprint of R17 initiator regions bound by low-salt-washed ribosomes from cells harvested 13 min after infection with T4 phage is illustrated in Fig. 1*b*. Here the ratios of the oligonucleotides corresponding to the three binding sites (Table 1, experiment 1, column *b*) are strikingly different from those obtained in the parallel reaction with ribosomes from uninfected cells (column *a*). The A protein is initiated as efficiently as the coat protein; the recoveries of the coat and synthetase binding sites relative to the A have diminished by factors of seven and four, respectively. In experiment 2, performed with the more degraded RNA preparation, a similar effect is observed, confirming that the results are independent of the integrity of the R17 RNA used for the binding assay.

A lower absolute level of binding (even at the A site) is consistently obtained with ribosomes from T4-infected cells. In addition, not all the labelled RNA recovered from these ribosomes can be attributed to the three known R17 binding sites. The several new spots are of unknown origin and, with a few exceptions, have not been previously detected. They are unlikely to be degradation products of the missing coat and synthetase oligonucleotides as demonstrated by a control experiment discussed later (Table 2, column *e*).

To find which component determines the proportions of the three R17 initiation sites bound, ribosomes from uninfected and T4-infected *E. coli* were washed with 2 M NH_4Cl buffer to remove their initiation factors[3]. The washed ribosomes and initiation factor preparations were then tested in various combinations (Table 2). Both experiments show that the recognition pattern of the three initiation sites in the R17 RNA is determined by some component(s) of the initiation factor fraction; the ratios obtained in the mixed infected–uninfected binding reactions (columns *b* and *c*) reflect only the origin of the factor preparation used. A lower absolute level of binding seems to occur when ribosomes from T4-infected cells are used; in light of the uncertain overall recovery of RNA fragments and the data presented in the preceding article[1], this observation is of questionable significance.

In experiment 1, parallel binding reactions were performed at 37° C in 70 μl. of solution containing 0·05 M ammonium cacodylate (*p*H 7·0), 0·1 M NH_4Cl, 0·01 M β-mercaptoethanol, 0·0003 M GTP, 0·006 M magnesium acetate, 5·5 $A_{260\ \mathrm{nm}}$ units of charged-formylated mixed tRNA, 1·2 $A_{260\ \mathrm{nm}}$ units of freshly prepared ^{32}P-labelled R17 RNA (specific activity about $1·5 \times 10^6$ c.p.m./μg), and 10 $A_{260\ \mathrm{nm}}$ units of (*a*) ribosomes from uninfected MRE600, (*b*) ribosomes from MRE600 infected with phage T4 (ref. 1), or (*c*) ribosomes from T4-infected cells for 7 min, then an additional 10 $A_{260\ \mathrm{nm}}$ units of ribosomes from uninfected cells for 8 min. In experiment 2, reactions were performed in 100 μl. containing the same concentrations of components as above, except: 6·6 $A_{260\ \mathrm{nm}}$ units of charged-formylated mixed tRNA, 3·0 $A_{260\ \mathrm{nm}}$ units of 2 week old ^{32}P-labelled R17 RNA (specific activity about 4×10^5 c.p.m./μg) and 15 $A_{260\ \mathrm{nm}}$ units of ribosomes from (*a*) uninfected MRE600, or (*b*) MRE600 infected with T4 phage. Transfer RNA and ^{32}P-labelled R17 RNA were prepared as described previously[3]. Ribosomes from MRE600 and from MRE600, collected 13 min after infection with T4 phage, were prepared by washing three times with buffer A[15], as described in the accompanying paper[1]. After 10 min of incubation—or as noted above for (*c*)—reaction mixtures were cooled to room temperature, digested for 15 min after the addition of 5 μg/ml. pancreatic ribonuclease, and sedimented in sucrose gradients as described in ref. 2. Fractions from the 70S ribosome peak were pooled and extracted with phenol in the presence of 0·2 M Tris-HCl (*p*H 7·4) and 0·1 per cent sodium dodecyl sulphate. Following several ethanol precipitations, the RNA was digested with T1 ribonuclease and fingerprinted as described[2]. After autoradiography, the oligonucleotide spots were cut from the papers and counted for 20 min in toluene scintillator. Each was then rinsed with toluene, eluted, digested with pancreatic ribonuclease and fractionated on DEAE-paper at *p*H 3·5 according to standard procedures[16]. For simplicity we present in the tables the molar ratios only of the initiator AUG-containing oligonucleotides; c.p.m. observed per phosphate for the A-site oligonucleotide ACCUAUG have been set equal to 1. Nevertheless, every spot marked A, C, or S in Fig. 2 was routinely counted and analysed, providing additional data for evaluation. In the case of the coat protein initiator region, CUUCUAACUUU is required in addition to the initiator AUG-containing oligonucleotide to define the site, for the sequence CAUG is not long enough to have a high probability of being unique in the R17 RNA molecule. CUUCUAACUUU, however, is always obtained in lower yields than CAUG because it arises from the 3′ end of the coat initiator fragment[2]. Where indicated by *, the oligonucleotide spots were found to contain pancreatic ribonuclease digestion products other than those expected, comprising greater than 50 per cent of the radioactivity; the values given have therefore been reduced to half the observed. All other oligonucleotides proved to be more than 90 per cent pure.

Does Specific Messenger Degradation Occur?

Altered recognition of the three R17 initiation sites with factor preparations from T4-infected cells could result from selective degradation of the coat and synthetase binding sites. Both low-salt-washed ribosomes and factor preparations from infected cells contain considerably more nucleolytic activity towards R17 RNA than comparable fractions from uninfected cells[1]. We therefore carried out several experiments which eliminate this explanation of the results.

First, we tested the effect of incubating R17 RNA in a complete binding system with low-salt-washed ribosomes from T4-infected cells before adding ribosomes from uninfected *E. coli* (Table 1, column *c*). The coat and synthetase oligonucleotides are recovered in quite good yield (compare with column *a*), showing that the inability of ribosomes from T4-infected cells to attach to these sites (column *b*) is not the result of selective messenger destruction.

Second, we have shown that if ^{32}P-labelled R17 RNA is preincubated in a binding mixture including factor preparations from T4-infected cells (with or without ribosomes) and then re-extracted with phenol before its addition to a reaction containing ribosomes and factors from uninfected cells (Table 3, columns *b* and *c*), the amounts of the coat and synthetase sites bound relative to the A initiator region are similar to the control (column *a*). Thus, in the fractionated system too, selective degradation of coat and synthetase sites does not occur. This type of experiment was necessary because we were unable to recover the coat and synthetase sites simply by adding equal amounts of factors from uninfected cells after incubation of R17 RNA in the presence of T4 factor prepa-

‡ Oligonucleotides containing more than one-half contaminants; the values given have therefore been reduced to half the observed.

In both experiments, parallel binding reactions were performed at 37° C in 70 μl. of solution containing buffers and salts as in Table 1, 6·5 $A_{260\,\text{nm}}$ units of charged-formylated mixed tRNA, 1·5 $A_{260\,\text{nm}}$ units of ^{32}P-labelled R17 RNA (from the same preparation, specific activity about $1\cdot5 \times 10^{6}$ c.p.m./μg in experiment 1 and $1\cdot2 \times 10^{6}$ c.p.m./μg in experiment 2), 10 $A_{260\,\text{nm}}$ units of high salt-washed ribosomes and 200 μg of initiation factors from uninfected or T4-infected MRE600 as indicated. Ribosomes were washed twice overnight in buffer B[15]; initiation factors were prepared from the first wash and titrated against the ribosomes as described previously[1]. Incubations were for 10 min in reactions (*a*) to (*d*); in (*e*) factors from uninfected cells were present for 8 min before adding additional factors from T4-infected cells and incubating a further 10 min; in (*f*) factors from T4-infected cells were present for 8 min before adding additional factors from uninfected cells and incubating a further 10 min. Pancreatic ribonuclease digestion, isolation and fingerprinting of the radioactive fragments, and quantitation and analysis of the oligonucleotide spots were performed as described in Table 1. All oligonucleotides were more than 90 per cent pure except as indicated in the footnotes.

Table 3. RELATIVE AMOUNTS OF INITIATION SITES BOUND BY RIBOSOMES FROM UNINFECTED CELLS USING R17 RNA PREVIOUSLY INCUBATED IN THE PRESENCE OF SEPARATED RIBOSOMES AND INITIATION FACTORS

Preincubation was performed in three complete binding reactions (70 μl.) as described in Table 2. The ^{32}P-labelled RNA used was 2 weeks old and had a specific activity of about 8×10^{5} c.p.m./μg; ribosomes and factors were as indicated in Table 1. Note that no ribosomes were present in (*c*). After 10 min at 37° C, the reaction mixtures were cooled and extracted with phenol following the addition of 1 ml. of 0·2 M Tris-HCl (*p*H 7·4), 0·1 per cent sodium dodecyl sulphate. The RNA from each of the resulting aqueous layers was ethanol precipitated twice and then redissolved in 5 μl. of 10^{-3} M EDTA before reincubation for 10 min at 37° C in a 70 μl. binding reaction containing ribosomes and factors from uninfected cells (concentrations of all components as in Table 2). Ribonuclease digestion of the complexes and subsequent isolation and analysis of the bound initiator fragments were as described in Table 1. Although the relative amount of coat site bound is low (because of the degraded RNA used) in three assays, it is not significantly different from experiment 2, Table 1, where it dropped by a factor of seven with ribosomes from T4-infected cells. On analysis, all oligonucleotides were more than 90 per cent pure.

rations (Table 2, column *f*). Taken together, it seems that recognition of the coat and synthetase sites may be blocked by some component of the initiation factor fraction from T4-infected cells, which is present in higher concentrations when the fractionated system rather than low-salt-washed ribosomes are used. Such a possibility has not been investigated further.

One additional control experiment (Table 2, column *e*) provides evidence that T4-specific degradation of T_1 oligonucleotides derived from the coat and synthetase initiator regions does not occur during isolation and preparation of the radioactive messenger fragments for fingerprinting. The relative ratios of the three sites are not greatly altered (compared with column *a*) when factors from T4-infected cells are added after preincubation of R17 RNA with ribosomes and factors from uninfected *E. coli*.

Initiation Factors and Control

A high-salt-wash fraction from ribosomes of *E. coli* contains many proteins, several of which are required for the initiation of protein synthesis[3]. Two factors[4], F1 and F2, are required for the initiation of polypeptide chains in the presence of synthetic polymers, and a third (variously characterized) factor is also necessary for initiation by natural messenger RNAs[4,5].

The altered initiation site recognition observed with ribosomes from T4-infected cells may result from a phage-coded modification or replacement of one or more of the known factors or of some unknown component(s) in the initiator factor fraction. The change induced by T4 seems to have two effects. First, the overall level of R17 initiation sites bound to ribosomes is decreased, as demonstrated in the previous article 1. This presumably is reflected by the inefficiency of RNA phage genomes to act as messengers in extracts of T4-infected cells (personal communication from W. Salser and R. F. Gesteland, and refs. 6 and 7). Second, and more important, the proportion of the three R17 sites recognized by ribosomes from T4-infected cells is changed in favour of the A site. Although this could conceivably result from an altered common initiation factor, a most attractive possibility is that multiple site-specific initiation factors exist in *E. coli* which are modified or replaced to varying degrees after infection by T4 phage. Were there several such factors, it would not be difficult to understand why protein synthesis is initiated at the three R17 cistrons with very different efficiencies *in vitro* (molar ratios of 20:6:1 for coat : synthetase : A protein, for instance, have been observed[8]). A multiplicity of factors recognizing different initiator sequences might also explain why the three ribosomal binding sites in the R17 RNA do not possess a common sequence which could act as a special signal for polypeptide chain initiation[2].

In conclusion, it seems not unlikely that in addition to changes at the level of transcription[9-11] modification or substitution of initiation factors may be a device used by virulent phages to turn the host's protein synthetic machinery to their own advantage.

We thank Drs Mark Bretscher, Francis Crick and Jeffrey Roberts for assistance with the manuscript. This work was supported by a postdoctoral fellowship (to J. A. S.) from the Jane Coffin Childs Memorial Fund for Medical Research, and a scholarship (to P. S. R.) from the Salters' Institute of Industrial Chemistry.

Interpretation of Cosmic X-ray and Gamma Ray Spectra

by

J. I. TROMBKA

Goddard Space Flight Center,
Greenbelt, Maryland

Changes in the slope of a measured distribution may be explained partially by the effect of the measurement process itself.

MANY papers published recently consider the cosmological implication of the diffuse X-ray and gamma ray background[1-4]. Certain breaks in the slope of the measured spectra have been noted, and some theoretical models have been proposed to explain these changes. These changes in slope may be explained partially by the effect of the measurement process itself.

The measured pulse heights reported are not identical with the true photon spectra (which are of theoretical significance), because the response of a real crystal detector to a delta-function photon spectrum is not a delta-function pulse height spectrum but is a characteristic continuous response function describing the energy imparted to the crystal. Before we compare theory with experiment, with respect to the measured pulse height spectra, the detector effects should be eliminated from these spectra.

Information concerning the differential energy photon spectrum is obtained by measuring the interaction of these photons with a detector system. This measured interaction spectrum, or pulse height spectrum*, does not necessarily reflect a one-to-one correspondence with the photon spectrum. Consider equation (1)

$$Y(V)=\int_{0}^{E_{\max}} T(E)S(E,V)\mathrm{d}E \qquad (1)$$

where $T(E)$ is the differential energy photon spectrum as a function of E, $S(E,V)$ is the detector interaction function which reflects the mechanisms of converting photons of energy, E, into a pulse height signal, V, at the output of the detector, and $Y(V)$ is the measured pulse height or interaction spectrum as a function of pulse height, V.

The analysis of gamma ray pulse height spectra in this particular spectral region must be accomplished by numerical methods because we cannot yet perform this inverse transform analytically. The integral in equation (1) can be written as a sum of discrete components. $T(E)$ is not a discrete distribution in energy, but a continuous energy distribution. The method for obtaining $T(E)$ is based on a theorem in sampling theory[5-7] and on the fact that there is a finite energy resolution of the detection system. If a distribution has no oscillatory component with a frequency greater than $f_{\max}$, then, the Shannon Sampling Theorem asserts, samples at discrete points not farther apart than $1/2\,f_{\max}$ describe the original function exactly. The original function may be reconstructed from the samples[6]. Thus equation (1) can be written as

$$Y_i=\sum_{j} T_j S_{ij} \qquad (2)$$

where Y_i is the measurement of $Y(V)$ in channel or pulse height i, T_j is the total number of gamma rays in energy group ΔE_j about E_j, and S_{ij} is the value of the jth standard spectrum in channel i. The S_{ij} components are the response of an NaI(Tl) detector to an incident monoenergetic gamma ray.

In applying Shannon's Sampling Theorem to the analysis of spectra obtained with NaI(Tl) crystals, sampling components S_{ij} are chosen so that their separation energy is no greater than the half width at half maximum of their photopeaks. Further, the integral in equation (1) is a sum of discrete energy components which describe an energy interval, ΔE, about a given E; the energy intervals between the ΔE samples are less than the half width at half maximum of the photopeak for the function, $S(E,V)$ (ref. 7). Thus the approximation formula, equation (2), is obtained. Equation (2) is now in a form where a valid numerical transformation can be obtained using techniques derived from the analysis of variance. The details of this derivation can be found in ref. 8 and unpublished work of J. I. T. and Schmadebeck. Using the least square principle, the method requires that

$$M=\sum_{j}\omega_i\Big(Y_i-\sum_{j}T_jS_{ij}\Big)^2 \qquad (3)$$

be a minimum, where ω_i is the statistical weight corresponding to the measurement of Y_i on channel i, and $\omega_i=1/\sigma_i^2$ (where σ_i^2 is the variance of the count in channel i). The other terms have been defined. The partial derivations of M are taken with respect to T in order to determine the minimum. The solution in matrix form is given by equation (4)

$$T=(\tilde{S}\omega S)^{-1}\tilde{S}\omega Y \qquad (4)$$

where Y is a vector describing the pulse height spectrum, S is an $m\times n$ matrix describing the discrete set of detector response function using the selection rule derived here, $\tilde{S}$ is the transposition of S, ω is a square diagonal matrix of the weighting functions, and T is a best estimate of the differential energy photon spectrum.

We now present some illustrations showing the nature of the problem and solutions that can be obtained. Assume that we are trying to measure a photon spectrum, $T(E)$, which can be described by a differential energy distribution, $T(E)\ \mathrm{d}E=E^{-1.5}\ \mathrm{d}E$. Fig. 1*a* shows such a distribution, and $T(E)\ \mathrm{d}E$ is indicated.

The spectrum is measured using a 3 × 3 inch NaI(Tl) crystal. The pulse height spectrum, $Y(V)\mathrm{d}V$, that would be obtained using equation (2) is indicated in Fig. 1*a*. If we attempt to determine the slope of the line of the pulse height spectrum, we find the slope to be $Y(V)\mathrm{d}V=V^{-2.3}\mathrm{d}V$, significantly different from $\boldsymbol{T(E)}$. Further, if we measure the pulse height spectrum only in the region up to about 60 keV, $Y(V)\mathrm{d}V=V^{-1.5}\mathrm{d}V$. If we measure the spectrum from 100 to about 300 keV, $Y(\mathrm{d}V)V = V^{-1\cdot7}\mathrm{d}V$, and $Y(V)\mathrm{d}V = \mathrm{d}V^{-2\cdot3}\mathrm{d}V$ if we determine the slope from 300 keV to 2 MeV. The shape of $Y(V)$ will depend on the size of the detector used, the resolution of the detector, the angular distribution of the incident and other factors. More important, if we assume some type of distribution like the photon inelastic scattering process proposed in ref. 1 (Fig. 1*b*) is superimposed on this power law distribution there is a deviation of $T(E)\mathrm{d}E$ from the power law distribution at higher energies. The detection system damps out this deviation in the photon spectrum, $T(E)$, and we lose the information concerning this power law process if we analyse the pulse height spectrum alone. This damping depends, again, on factors of crystal size, resolution and the angular distribution of the incident flux. Thus almost any kind of solution may be obtained if the pulse height spectrum is mistakenly used for correlating theory with experiment. Fig. 2 shows both the measured pulse height spectrum (*a*) and the analytically derived photon spectrum (*b*) obtained using the analytical method just described. The measured pulse height spectrum (Fig. 2*a*) was obtained during a balloon flight at approximately 100,000 feet, using a 3 × 3 inch NaI(Tl) detector (private communication from Peterson). The 0·51 MeV annihilation ray peak is easily recognized in the pulse height spectrum. Without assuming any *a priori* knowledge of the incident photon spectrum, the numerical transformation was performed and the photon spectrum obtained. After the numerical analysis, two other discrete lines became more distinct above background. These lines were later identified as the potassium (^{40}K) line caused by the presence of this material in the atmosphere, and the magnesium (^{24}Mg) line attributed to excitation induced by the cosmic ray flux on the structural material of the gondola. Once identified, these discrete lines were subtracted from the total photon spectrum to obtain the pure continuous spectrum.

---

* The term pulse height is used to describe the spectra, because the detector output is usually an analogue voltage or current signal. This analogue signal is digitized using a multichannel pulse height analyser.

The photon spectrum (Fig. 2*b*) was used to reconstruct the pulse height spectrum (equation 2). The results are shown in Fig. 2*a*. It is almost impossible to differentiate between the two curves.

In Fig. 2*b* the last two points are higher than the continuum. These two points contain information about all the energies greater than those observed in the measured energy region. These "end effects" occur when only parts of the total spectrum are analysed.

In summary, we have developed a method to determine both the pulse height spectrum from a known photon spectrum and the photon spectrum from a measured pulse height spectrum, and information derived from these two spectra differs significantly. Using a 3 × 3 inch NaI(Tl) detector, if we attempt to measure a photon differential energy spectrum characterized by a $T(E)\mathrm{d}E = E^{-1\cdot5}\mathrm{d}E$ distribution, we obtain a pulse height spectrum with a number of breaks in slope: a $-1\cdot5$ slope in the energy region up to 60 keV, a $-1\cdot7$ slope in the energy region up to 300 keV, and a slope of $-2\cdot3$ from 0·3 MeV to 2 MeV. The technique for deriving the photon spectra from the measured pulse height spectra eliminates the effects of instrumental response, and further allows for meaningful comparison with data from different detectors.

LETTERS TO THE EDITOR

PHYSICAL SCIENCES

Telemetry from the First Chinese Artificial Earth Satellite

THE first Chinese artificial Earth satellite was launched at approximately 1330 UT on April 24, 1970. The announcement of the launch, giving a transmission frequency of 20·009 MHz, was made in Peking at 1232 UT on April 25. First signals were received at Kettering Grammar School at 1402 UT, towards the end of the twelfth orbit of the Earth.

As announced later in Peking, the signals consist of a 1 min cycle of alternate music and telemetry[1]. The first 40 s are devoted to a repetition of the music of "Tungfanghung"—"The East is Red" (Fig. 1)—followed by an interval of 5 s. Then follows 10 s of telemetry and, after a further interval of 5 s, the complete sequence is repeated.

The telemetry consists of audio tones which seem to be quantized in steps of 13·6 Hz. The first tone has the same frequency as the highest musical tone. The duration of the first tone is twice that of succeeding tones and its frequency is 100 times the minimum difference between tones, so it is considered to serve as a calibration point nominally equal to 100 per cent. Then follow twenty tones of equal duration, terminated by several rapid tones.

Values of the initial tone and twenty channels, expressed as a percentage of the maximum observed frequency, are given for revolutions 24 and 99 in Fig. 2. To date, no frequency below 68 per cent has been observed. Seven of the channels had this minimum value on revolution 99 and this prompts speculation that transducer outputs are quantized in 32 levels before transmission. The fact that other values cluster around 84 per cent (or level 16) supports such speculation. Read-out as a five-bit binary code for storage and data processing is therefore a possibility.

Is the Diffuse Interstellar Absorption Band at 4430 Å caused by Trivalent Iron?

ALTHOUGH the broad diffuse interstellar absorption bands have been known for more than 30 years, they still defy identification. It has been suggested that the bands may be caused by electronic transitions in impurity ions in grains[1]. Here I show that the wavelength, asymmetry and half-width of the 4430 Å band, in particular, are compatible with absorption bands marking the $^6A_1(S)\rightarrow{}^4A_1{}^4E(G)$ transitions in Fe^{3+} in some terrestrial silicates. The absorption spectra of Fe^{3+} in octahedral sites in some garnets are used for comparison, because these spectra are now reasonably well understood. Because Fe^{3+} is a $3d^5$ ion, however, the d–d spectra are similar for both octahedral and tetrahedral complexes.

Fig. 1 shows portions of the absorption spectra of the natural garnets and radite[2], $Ca_3Fe_2^{3+}Si_3O_{12}$, and schorlomite[3], a high-Ti garnet corresponding to an andradite but with approximately 25 per cent of the tetrahedral Si^{4+} and 10 per cent of the octahedral Fe^{3+} ions replaced by Al^{3+} and Ti^{4+} ions[4]. Each oxygen is common to two eight-cornered Ca^{2+} polyhedra, one Fe^{3+} octahedron and one Si^{4+} tetrahedron[5]. In schorlomite, each Fe^{3+} ion has an average of 1·5 Al^{3+} or Ti^{4+} ions in the next-nearest-neighbour tetrahedral sites. The principal bands at 4400 Å mark the $^6A_1(S)\rightarrow{}^4A_1{}^4E(G)$ transitions in Fe^{3+}; they are relatively sharp for transition-metal d–d bands because the transitions are field-independent[2]. The oscillator strengths are $3·5\times10^{-6}$ for andradite and 6×10^{-5} for schorlomite. Substitution of the tetrahedral Si^{4+} ions by the larger, less covalent Al^{3+} or Ti^{4+} ions destroys the inversion symmetry at adjacent octahedral Fe^{3+} sites by distorting the oxygen octahedra and modifying the charge distribution within these octahedra[3]. Accordingly, in schorlomite, the Fe^{3+} transitions may borrow intensity from charge-transfer transitions, such as $O^{2-}2p\rightarrow Fe^{3+}3d$, through crystal field mixing of odd-parity charge-transfer states with even-parity d states. Replacement of Si^{4+} ions by Al^{3+} and Ti^{4+} ions also has the effect of broadening the Fe^{3+} bands; the half-widths of the 4400 Å bands in andradite and schorlomite are 100 Å and 260 Å respectively, compared with a half-width of 150–200 Å for the 4430 Å band in spectra of supernova SN–NGC–2713[6–8].

The $^4A_1(G)$ and $^4E(G)$ levels of Fe^{3+} are not exactly degenerate and in well resolved spectra two component bands are observed (Fig. 1). In less well resolved spectra a shoulder is observed on one of the wings of the 4400 Å band. The image tube observations of Brück and Nandy[9] show that the 4430 Å interstellar band can be highly asymmetric, the longer wavelength side being the steeper. This indicates the presence of a weaker band on the shorter wavelength flank. Hence the asymmetry of the 4430 Å band can be explained by transitions in Fe^{3+}.

The contours of the Fe d–d bands in the silicates are not changed significantly by lowering the temperature to 77 K, although a slight reduction in width occurs. It is conceivable that the further lowering of the temperature would markedly reduce band widths, but the width and oscillator strength of the 4400 Å bands seem to depend more on site distortions and next-nearest-neighbour interactions.

The question of band intensities is of great importance because of the relatively small oscillator strengths of Fe^{3+} d–d bands. With an absorption of $\simeq 0{\cdot}1$ mag. kpc^{-1} at 4430 Å, the density of absorbers[1] is $N \simeq 3 \times 10^{-9}.f^{-1}$ cm^{-3}, where f is the oscillator strength. If, say, $f = 2 \times 10^{-5}$, $N \simeq 1{\cdot}5 \times 10^{-4}$ atoms/cm^3, and for a total grain density of 10^{-11} cm^{-3}, we require $\sim 1{\cdot}5 \times 10^7$ atoms/grain. Thus if each grain has $\sim 10^9$ atoms and if my proposal is correct, interstellar grains contain significant concentrations of Fe^{3+}-bearing silicate.

The Fe^{3+} ions in interstellar dust are likely to be in a silicate matrix because of the position of the ultraviolet absorption edge. In water, for example, charge-transfer bands of hydrolysed Fe^{3+} complexes obliterate the weaker d–d bands. In fact, it is only in the past few years with the study of silicate minerals that the blue region has been sufficiently transparent to resolve weak Fe^{3+} d–d bands. It should be emphasized that the silicate need not necessarily be andradite. Electronic transitions to the ${}^4A_1{}^4E(G)$ levels are observed in the range 4200–4500 Å in the spectra of other silicates also[10], with, in some cases, very different oscillator strengths, depending on the interactions occurring in the crystal structures.

Because Fe^{3+} is a $3d^5$ ion, the energy-level diagram[11,12] is the same for octahedral and tetrahedral complexes. The absorption spectra show similar features[2,13], for example, the ${}^4A_1{}^4E(G)$ levels in Fe^{3+} in tetrahedral sites in phlogopite are also observed at 4400 Å. Unfortunately, d–d spectra of tetrahedrally bonded Fe^{3+} complexes are not yet fully understood. Nevertheless, the energy-level diagram[11,12] shows that the levels ${}^4T_1(G)$, ${}^4T_2(G)$ and ${}^4A_1{}^4E(G)$ are more closely bunched in tetrahedral complexes than in octahedral, because of the weaker crystal field. Bearing in mind that transitions to the ${}^4T_2(G)$ and ${}^4T_1(G)$ levels are observed at ~ 6000 Å and ~ 10000 Å in octahedral complexes[10], it is conceivable that the 4870 Å and 5100 Å bands in interstellar dust[6,7] may mark the same transitions in tetrahedral fields. Significantly, Faye[13] assigns two bands in spectra of phlogopite at ~ 5000 Å to transitions to the ${}^4T_1(G)$ and ${}^4T_2(G)$ levels in tetrahedral Fe^{3+}.

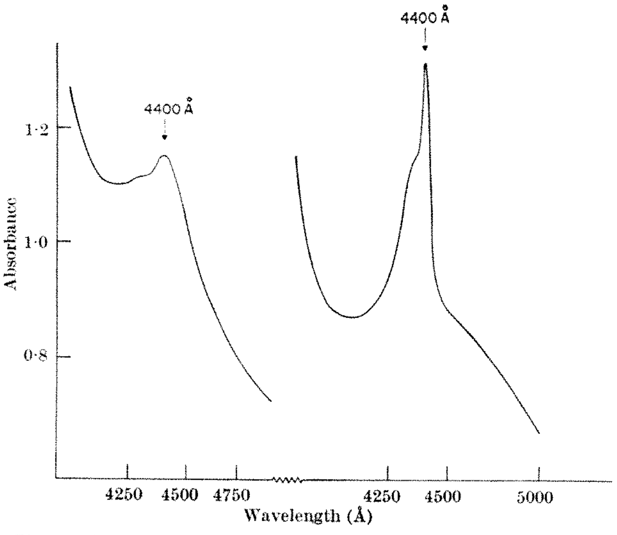

Fig. 1. Absorption spectra of terrestrial schorlomite (left hand spectrum) and andradite (right hand spectrum). Sample thicknesses are respectively 0·0015 cm and 0·03 cm. Temperature = 290 K.

The spin-allowed transition ${}^5T_2 \leftrightarrow {}^5E(D)$ in octahedral or tetrahedral Fe^{2+}–O complexes is generally observed in the near-infrared[2]. The 4430 Å band cannot therefore be assigned to Fe^{2+}.

It seems reasonable to suggest that the 4430 Å interstellar absorption band may be due to the ${}^6A_1 \rightarrow {}^4A_1{}^4E(G)$ transition in Fe^{3+} ions located in a silicate matrix.

Anomalous Recombination Line 166α

A SPECTRAL line corresponding to the "anomalous" recombination line at 5,011 MHz (109α) described by Palmer *et al.*[1] has been detected at 1,425 MHz (166α) in the HII regions NGC 2024, W3 and possibly W43. The intensity of the anomalous line compared with that of hydrogen is much greater for the 166α line than for the 109α line. A similar enhancement but of smaller magnitude has recently been reported for the anomalous 134α line by Zuckerman and Palmer[2].

The observations were carried out in June 1969 using the Mark I 250 foot telescope (beamwidth 18 min × 12 min arc) in association with the 256 channel autocorrelation spectrometer[3]. The total system noise of the receiver was about 80 K. The spectrometer was used with a 5 MHz bandwidth; the instrumental profile has a $(\sin^2 x)/x^2$ form with a half power width of 34·4 kHz and a 5 per cent secondary response 58·6 kHz from the main response. The receiver was used in a frequency switching mode in which the signal was compared with frequency bands displaced $\pm 1{\cdot}3$ MHz. The resulting spectra had curved baselines with maximum slopes of about 0·5 K MHz^{-1}. These were removed by subtracting a fourth order polynomial which had been fitted to the parts of the spectra adjacent to the recombination lines.

The resulting spectra from NGC 2024, W3 and W43 are shown in Fig. 1. It has been suggested by Goldberg and Dupree[4] that the element emitting the anomalous line is carbon and hence the frequencies of the helium and carbon lines (1,425·314 MHz and 1,425·445 MHz) are marked on the figure relative to the frequency of the hydrogen recombination line (1,424·734 MHz). For NGC 2024 and W43 the line does not lie exactly on the frequency of the carbon line, but this could be accounted for by the carbon having a different velocity from the hydrogen. The line temperature of the anomalous line in NGC 2024 is about 50 per cent of the hydrogen line temperature and may be even larger if the line is not resolved in frequency. By comparison the anomalous 109α line temperature, given by Palmer *et al.*, is about 10 per cent of the hydrogen 109α line temperature. The helium 166α line is $\lesssim 6$ per cent of the hydrogen line intensity in NGC 2024 and is consistent with the results

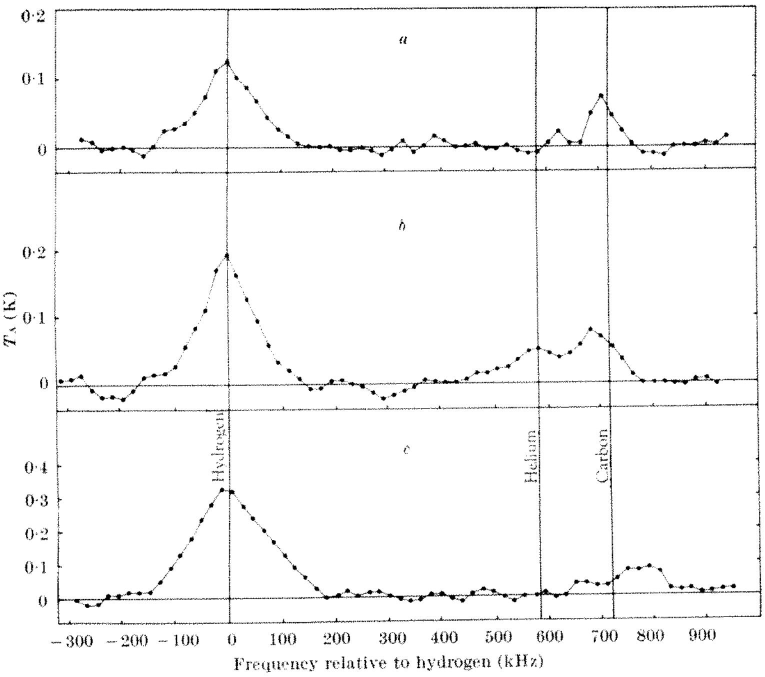

Fig. 1. Spectra of NGC 2024 (*a*), W3 (*b*), and W43 (*c*) in the vicinity of the frequency of the hydrogen 166α transition (1,424·734 MHz). The frequencies of the carbon 166α and the helium 166α are shown assuming that they have the same velocity as the centroid of the hydrogen profile. The velocities of the hydrogen centroids, relative to the local standard of rest ($V_{l.s.r.}$), are: *a*, +7·6 km/s; *b*, −40·1 km/s; *c*, +99·4 km/s.

of Palmer *et al.* for the 109α line. An estimate of the width of the anomalous lines can be made from Fig. 1, although the relatively wide spectrometer resolution makes the results somewhat inaccurate. The half power width for NGC 2024 is 43^{+20}_{-30} kHz after instrumental broadening has been removed. It is difficult to estimate the width of W3 on account of confusion with helium.

Table 1. LOWER LIMITS ON SEVEN SOURCES

W29	M8	18 00 34	−24 22	90	< 0·07	—	—
W38	M17	18 17 33	−16 12	90	< 0·03	—	—

The errors quoted for E_L/E_H for W12, W3 and W43 are r.m.s. values.

Lower limits on seven other sources are given in Table 1. These are essentially a measure of the peak to peak error, and are given in units of E_L/E_H, the ratio of the energy in the anomalous line to the energy in the hydrogen line. The last two columns show the values of E_L/E_H for the 109α lines[1] and the 134α lines[2].

E_L/E_H varies considerably between the sources. The values of NGC 2024 and W3 are 0·2 to 0·35, whereas at the other extreme the ratio is < 0·07 for M8 and M17. This indicates that the emission is strongly dependent upon the parameters of the HII regions themselves or of the interstellar medium lying in front of the HII regions[5]. It is not yet clear from the data available, however, what parameters are significant in producing the enhancement of the anomalous line relative to hydrogen.

Another interesting point is the variation of E_L/E_H with frequency. For the 109α line E_L/E_H is only 3 per cent for NGC 2024, whereas for the 134α line it is 6·4 per cent and for the 166α line E_L/E_H is at least 30 per cent. This definitely shows that the line is not due to an abundance anomaly, for the ratio would be independent of the *n* quantum number of the states involved. Similarly, it is improbable that both the hydrogen and the anomalous line are emitted from HI regions as suggested by Greenberg[6], because again one would not expect E_L/E_H to vary with *n* value. The smaller widths of the anomalous lines relative to the hydrogen lines as shown in Fig. 1 and previous observations[1,2] also indicate[5] that both the hydrogen and anomalous lines do not arise from an HI region.

It seems unlikely that the invocation of dielectronic recombination, already in difficulties in explaining a factor of ~60 for the 109α line, can produce overpopulations of ~600 for the 166α line (assuming $N_{\text{carbon}} = 5 \times 10^{-4} N_H$) unless unreasonably high temperatures and low electron densities are assumed[7,8].

The results are not in conflict with the theory of Dupree and Goldberg[5] nor that of Zuckerman and Palmer[9]. The former proposes that emission from the upper states of carbon atoms in HI regions, adjacent to HII regions, is enhanced by stimulated emission caused by the continuum radio emission from the HII region. The latter theory proposes that the emission occurs in cool, high-density HI regions within the HII regions. These are optically thick to 13·6 eV ultraviolet radiation and hence only elements with ionization potentials less than this, for example carbon with 11·3 eV, will be ionized. Before the compatibility of these theories with the observations can be checked, a knowledge of the behaviour of the b_n factors for carbon at temperatures ~ 100 K is required. These are as yet not available.

The width of the anomalous line in NGC 2024 at 5,011 MHz is 64 kHz as measured by Palmer *et al.* and hence at 1,420 MHz one would expect the width to be 18 kHz. The observed width is 47^{+20}_{-30} kHz, and hence because of the errors it is impossible to state, on the basis of the present observations, that the line width is definitely deviating from Doppler broadening. The results of Zuckerman and Palmer[2] suggest that the 134α line may be broadened, but again the errors are rather large. If such a deviation existed it might be the result of "Stark" broadening[10] occurring in the type of high density region proposed by Zuckerman and Palmer[9].

The observations show that the population of the upper states of the element emitting the anomalous line is far from thermodynamic equilibrium, whether it is emitted in the same or a different region from the hydrogen. To obtain more information on these phenomena it will be of interest to observe these anomalous lines at larger *n* numbers.

Temperature Microstructure in a Fresh Water Thermocline

RECENT measurements of microstructure in the ocean[1-4] have led to considerable speculation about physical processes that lead to a steplike distribution of temperature, salinity and velocity. Briefly, one school of thought explains the microstructure in terms of interleaving of layers originating at different locations[1,2]. The other school suggests that the transport processes responsible for the vertical diffusion of heat, salt and momentum may inevitably result in the development of layers; the most striking theory, the so-called salt finger mechanism developed by Turner, Stommel and Stern[5-7], depends on the difference between the molecular diffusivities for salt and heat. This mechanism works only in a statically stable ocean where the temperature gradient is stable, but the salinity gradient is unstable, or in the reverse situation. Tait and Howe[3] have recently published profiles that strongly favour the salt-fingering process for layers under the Mediterranean outflow, but regular steps in temperature and salt of this kind are rare: the great majority of ocean microstructure is much more variable. Dr R. W. Stewart (private communication) has suggested that this microstructure is caused by the difference between the (turbulent) transport coefficients for buoyancy and momentum. No adequate theory for this buoyancy–momentum process has yet been developed, but the low Reynolds number turbulent spots discovered by Woods[8,9] may be important. Temperature microstructure in a freshwater lake at least demonstrates that salinity gradients are not an essential factor in the generation of ocean microstructure. The occurrence of such microstructure in freshwater lakes seems likely from transparency observations made by Whitney[11].

Preliminary observations in Lake Bala in Merionethshire[12] gave positive indications of microstructure, and we decided to make further observations of the seasonal thermocline of Loch Ness in September 1968. This Scottish freshwater lake is about 30 km long and 1 km wide and has an average depth of nearly 200 m.

Temperature and temperature gradient profiles were measured with a thermocline microstructure probe[10] and a bathysonde system operated from the RV Prince Madog. In calm weather the microstructure probe is capable of better than 2 cm vertical resolution. The bathysonde has lower resolution (~40 cm) but can make soundings to the full depth of the lake and is less seriously affected by ship movement in adverse weather conditions.

The bathysonde sounding shown in Fig. 1*a* illustrates the gross thermal structure of the lake. There is a mixed layer approximately 30 m thick at the surface below which the seasonal thermocline extends down to about 100 m. A rich microstructure is evident on the thermocline with alternating regions of intense and weak temperature gradient (sheets and layers).

Below 80 m, the mean temperature gradient is small but fine structure is still present. A series of almost isothermal layers about 5 m thick can be seen in Fig. 1*b*.

The thermocline features can be seen in more detail in the microstructure probe soundings (Fig. 2*a*). The profile in Fig. 2*b* was taken with the same apparatus in the Mediterranean, 20 km south of Malta. There is a marked similarity between the form and spacing of the microstructure in these two profiles. The principal difference is the existence of negative temperature gradients (inversions) in the Mediterranean profile. Such features would be unstable in freshwater, but commonly occur in the ocean where stability may be maintained by salinity variations. Dr C. S. Cox (unpublished manuscript of Scripps Institution of Oceanography) has made similar measurements at a depth of 400–600 m in the Pacific using a slowly falling probe with a resolution of 1 cm. The spectral characteristics of the vertical scale of this deep microstructure are essentially the same as those found at Loch Ness and near Malta.

Fig. 3 shows a sequence of eleven temperature profiles observed at 15 min intervals. The detail of the profiles varies, but certain step features (for example, at about 11·1° C) persist throughout the sequence indicating a time scale of hours at least. Observations of the persistence of similar large step features in the ocean have

b

Fig. 1. *a*, Temperature profile (on the right) and temperature-gradient profile (on the left) at Loch Ness station 9 on September 21, 1968. Both profiles have been drawn from digital data spaced at intervals of 20 cm, obtained from the bathysonde. *b*, An expanded scale plot of the temperature in the bottom layer showing a number of almost isothermal layers, differing in temperature by only a few hundredths of a degree Celsius. Temperature resolution is limited by the digital system of recording to ±0·001° C.

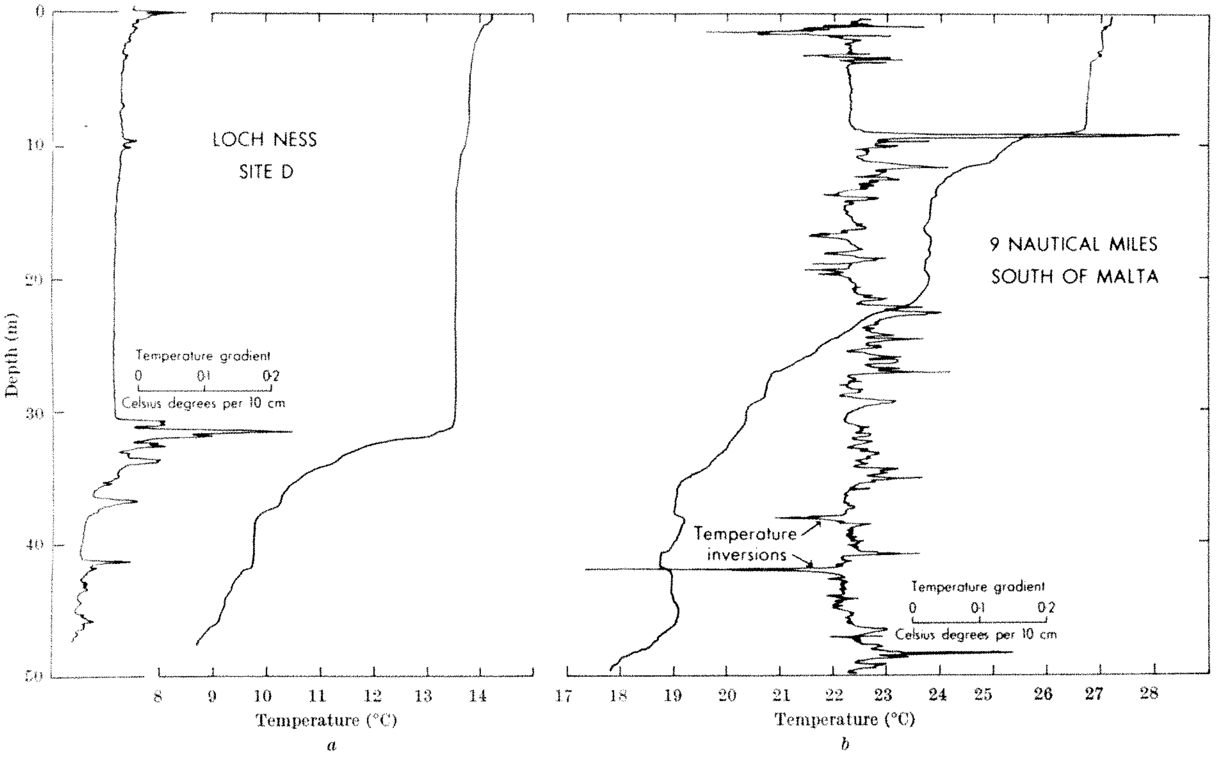

Fig. 2. *a*, A temperature and temperature-gradient sounding through the seasonal thermocline in Loch Ness, September 19, 1968. The temperature-gradient profile represents the temperature difference across two platinum resistance thermometers fixed 10 cm apart; the temperature profile is obtained from a third thermometer and the depth for a pressure transducer. (There is a slight instrumental drift with depth in the temperature-gradient trace, which is also displaced upward by approximately one metre and has arbitrary zero.) *b*, A temperature and temperature-gradient sounding through the seasonal thermocline of Malta, August 1968, made with the same microstructure probe as was used in the Loch Ness expedition. The profile is plotted to a vertical resolution of 10 cm; the sensors have a somewhat better resolution.

recently been reported by Cooper and Stommel[4]. The apparent lack of persistence of some of the smaller features in Fig. 3 may be a result of mixing caused by the protective framework surrounding the bathysonde temperature sensor; successive soundings made at 30 min intervals with the microstructure probe did show persistence in these fine details.

We were unable, during our short stay in the loch, to measure satisfactorily the spatial extent of individual features of the fine structure. We did, however, find in the loch an interaction between the horizontal layering and horizontal temperature gradient. During our stay in Loch Ness, the temperature of the mixed layer at the south-west end of the loch was almost exactly 1° C lower on the north-west side than on the south-east side. Our measurements made between Fort Augustus and a point midway between Invermoriston and Foyers suggest that a sharp 1° C "front" runs parallel to the (SW–NE) axis of the loch. Fig. 4 shows three microstructure soundings at positions *A*, *B*, *C* on the map. A comparison of the microstructure at the warm water sites, *A* and *B*, shows that the general shape of the temperature profile is similar, and that many of the temperature-gradient spikes (sheets) occur at the same temperature (although their depths do not necessarily correspond, for the isotherms are tilted by internal seiches and waves) and have a similar form in each profile. At the cold water site *C*, the broad thermocline profile is more stepped and the sheets do not occur at the same temperature as at *A* and *B*. This method of sheet-by-sheet comparison contains an element of subjective assessment, but a satisfactory objective test for the coherence of individual features in successive profiles has not yet been devised. The method shows, however, that many of the sheets in Loch Ness extend at least 1/2 km horizontally when the surface temperature gradient is small, but that a 1° C "front" acts as a barrier to the microstructure. This conclusion has since been shown to hold for the Maltese seasonal thermocline, details of which will be published later. A similar comparison between the profiles at sites *A* and *B* and another warm site *D* shows that the strongest sheets (those with the greatest temperature difference) extend at least as far as 1·5 km.

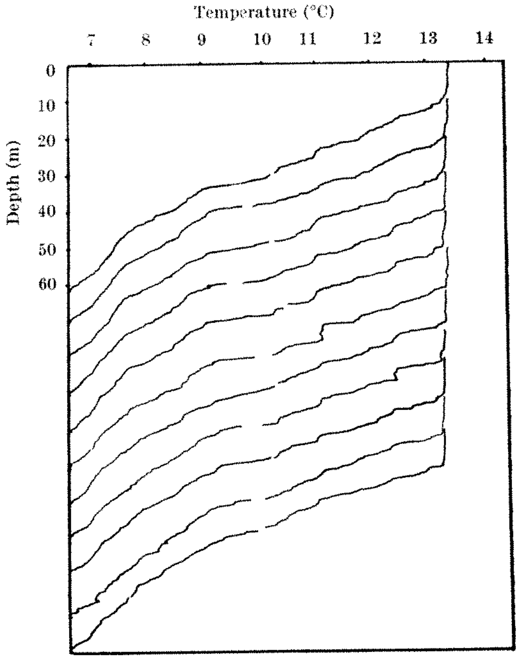

Fig. 3. Repeated temperature profiles at Loch Ness station 12B, September 20, 1968, at 15 min intervals. Each sounding has been offset by 10 m from the preceding one. The short break in the trace is caused by a change of range on the bathysonde.

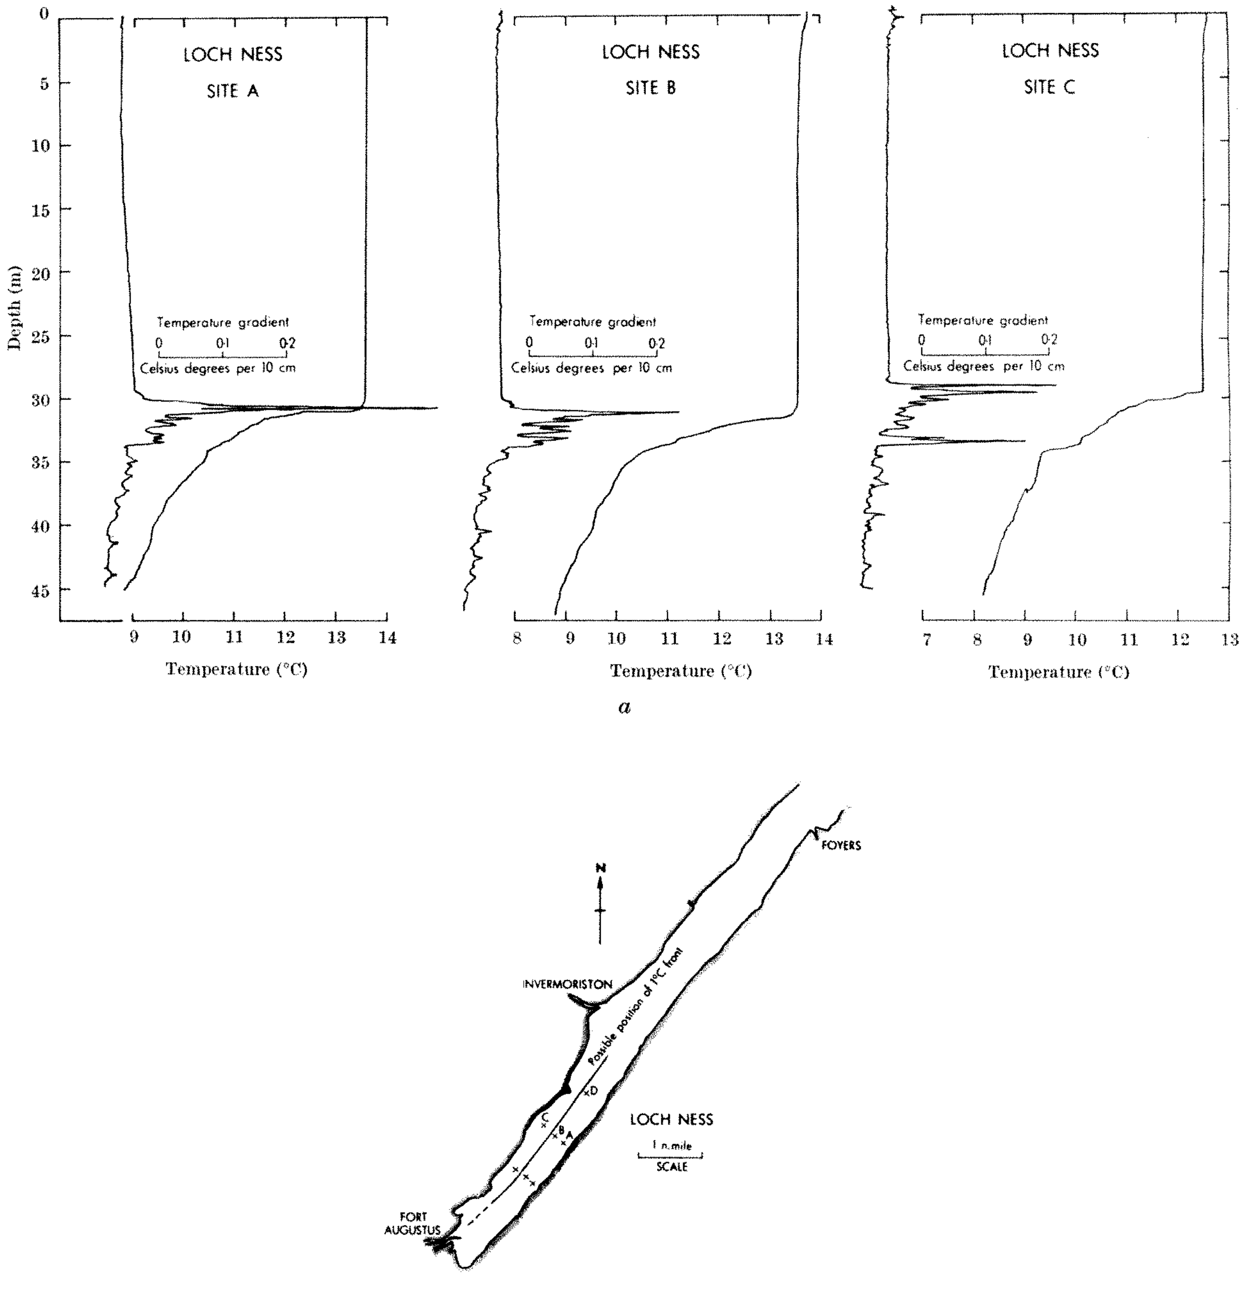

Fig. 4. *a*, Temperature microstructure at positions *A* and *B* in the warm water and position *C* in the cold water. The temperature sheets in *A* and *B* do not penetrate the front and an independent microstructure is found on the other side at *C*. *b*, Approximate position of the "front" at the Fort Augustus end of Loch Ness.

The existence of such a microstructure, in the absence of any dissolved or suspended matter, suggests that salt does not necessarily play an essential part in the formation of microstructure on the oceanic thermocline. The vertical scale of the thermocline microstructure found in Loch Ness is indistinguishable from that found in the Mediterranean thermocline and in weakly stratified water in the Pacific Ocean. Most of the fine structure detected in Cox's[14] probe extends for at least 50 m, while the coarser features detected by Cooper and Stommel[4] seem to extend for several kilometres. The temperature differences across the sheets in Loch Ness thermocline profiles are about 20 times greater than those in Cox's Pacific profiles. The sheets' horizontal extent is correlated with their relative, rather than absolute, static stability. If, as we suspect, the layering depends on the form of the turbulent spots found off Malta, then it is likely that the correct parameter for classifying the sheets is their gradient Richardson number[13] because this controls the turbulence. A suitable probe for measuring the local gradient Richardson number to a vertical resolution of 10 cm has, however, yet to be developed.

Variable Boundary, Two Dimensional Tidal Model

THE application of digital computers to tidal problems has revived interest in tides, including the problem of the numerical tidal modelling of estuaries or bays in one or two dimensions. Usually computer programs have been designed to find a solution for one tidal constituent, the M_2 tide, and are applicable only to specific estuarine systems. We report here a two dimensional program which can easily be used to solve semidiurnal tidal problems for many estuaries.

The mathematical basis for the analysis is derived from the two dimensional explicit model originally developed[1] for the North Sea. Other authors[2,3] have given the full mathematical derivations and only the basic differential equations will be given here. The equations of motion in two horizontal dimensions and the equation of continuity are used as follows:

$$U_t + r(U^2 + V^2)^{1/2}\frac{U}{H} + fV + gZ_x = 0$$

$$V_t + r(U^2 + V^2)^{1/2}\frac{U}{H} - fu + gZ_y = 0$$

$$(HU)_x + (HV)_y + Z_t = 0$$

where U is the x component of depth-mean velocity, V the y component of depth-mean velocity, Z the tidal elevation above equilibrium depth, r the friction coefficient, f the Coriolis parameter, H the total water depth and g the gravitational acceleration. Atmospheric and convectional influences are neglected and the water is assumed to be homogeneous.

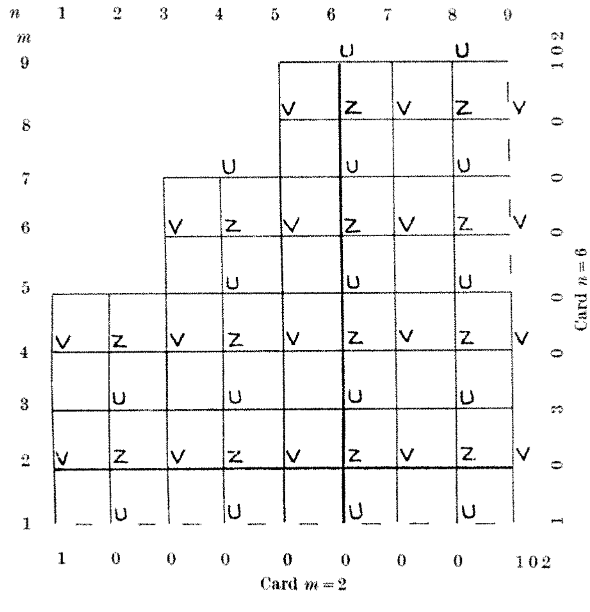

Fig. 1. Part of the two dimensional grid; typical column and row through Z-point, with associated matrix and input cards.

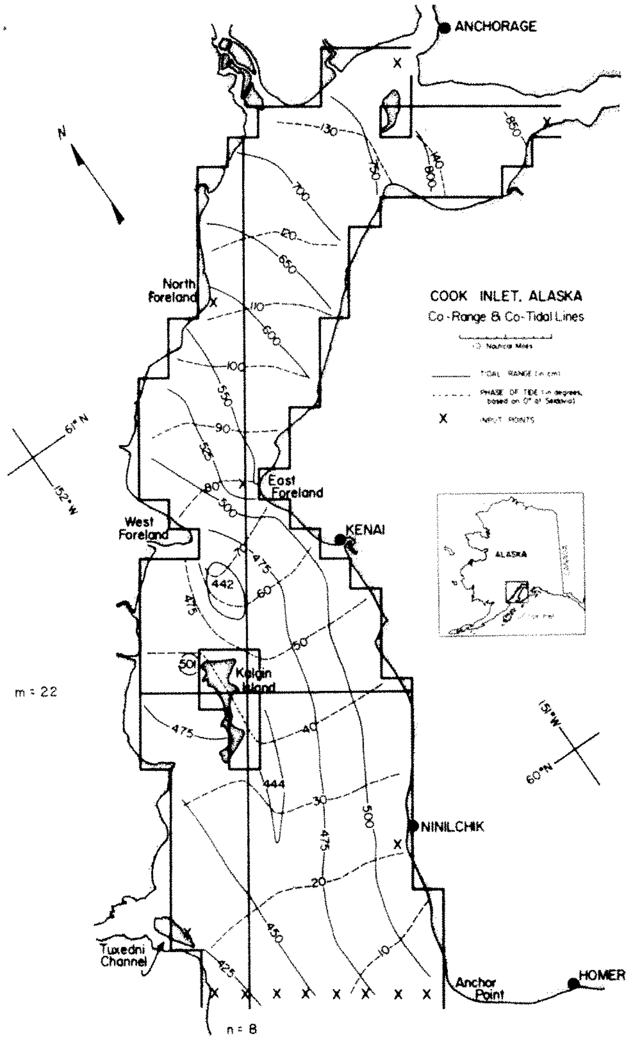

Fig. 2. The grid chosen for Cook Inlet, Alaska, and the predicted co-range and co-tidal lines.

Solution of the equations, by finite difference methods, is facilitated by the grid layout (Fig. 1) and is staggered in time and space. The grid can be terminated at alternate lines in both directions to represent either open or closed boundaries. The only requirements for the grid are that the boundaries in the x direction be terminated by lines of U velocity points and those in the y direction by V velocity points. Within these requirements any shape of boundary can be represented. In practice the boundaries are chosen to coincide with the coastlines of the estuary that is being modelled.

The most novel and useful feature of our model is the way in which the gridshape is specified. Separate specifications are made for horizontal and vertical grid lines, giving the immediate advantage of greatly reducing the number of special calculations to be made in corners of the grid[4]. This is achieved by using an integer matrix.

The integer control matrix is built in the computer from separate linear integer matrices for each row and column of the grid. In our program the input is by punched card, and typical cards for row $m = 2$ and column $n = 6$ are shown in Fig. 1. The V and Z points and the U and Z points lie in the even-numbered rows and columns respectively. Only these rows and columns need be specified in building a matrix. For example, consider $m = 2$ in Fig. 1.

The digit 1 signifies land or a sea area needing no computation. It is placed in the odd-numbered boundary column. Further 1s designate other boundaries and must occur in pairs in any row or column. For a sea/sea boundary a digit 3 is placed in the odd-numbered column to the calculation side of the boundary. To avoid ambiguity, at least one blank odd-numbered column must lie between any code digits 3. A code digit 2 in the next odd column after the boundary terminates the matrix.

The integer matrix controls the program operation. No computations are carried out for points outside a pair of 1s, nor beyond the 1 followed by a 2. At boundary points with 1s, V or U is set to zero for rows or columns respectively except when a digit 3 refers to that point, in which case

$$\frac{\mathrm{d}V}{\mathrm{d}y} \text{ or } \frac{\mathrm{d}U}{\mathrm{d}x}$$

is set to zero instead. The master integer matrix thus controls the program operation. It supervises the allocation of depths, the computation of currents and tidal heights and the calculation of mean range, phase of tide, current ellipses and other parameters. For application of the program to a new inlet, only the integer matrix need be changed and new input data read into the computer.

The model has been applied to several examples, both theoretical and practical, with excellent results. The co-range and co-tidal lines predicted by the model for Cook Inlet are shown in Fig. 2. The results are for a semi-diurnal tide of period 12·42 h and amplitude of one half the mean range. The greatest error in the range was 8 per cent in the vicinity of Kenai.

We think the model should find many applications because of its versatility and simplicity. It is written in Fortran IV with some sub-routines in machine language for the IBM360/40. It is readily adaptable to other machines capable of handling Fortran IV language. Once the program is available it takes only 1 or 2 days' work to make a new master matrix starting from the charts of the area under investigation.

Our work was supported by the US Office of Naval Research.

Lithification of Deep Sea Sediments by Pyrite

UNIQUE pyrite-cemented silty sand layers have been found in three piston cores taken from the North Carolina lower continental rise at depths from 4,770 to 4,950 m (Fig. 1). The layers are approximately 0·5 cm thick and consist mainly of terrigenous grains in a cement identified as pyrite by X-ray diffraction analysis. None of the precursor iron sulphides commonly associated with sedimentary pyrite[1] were found. Single layers at core depths of 530 and 870 cm were noted in cores *B* and *C* respectively (Fig. 1). In core *A*, two pyritized silty sand layers occur at depths in the sediment of 540 and 560 cm. Fig. 2 is a photograph of a fragment of one of the lithified sand layers. The rock has approximately the same 6 cm diameter as the piston core cutter, suggesting strongly that the rock was punched out of a pyritized sheet of unknown lateral extent by the core tube.

Thin sections of the rocks reveal the presence of individual euhedral cubic pyrite crystals as well as the relative abundance of the framework grains. Calcareous grains incorporated into the rocks seem to have undergone selective dissolution during cementation. Outer surfaces of the two foraminifera tests in Fig. 3 exhibit

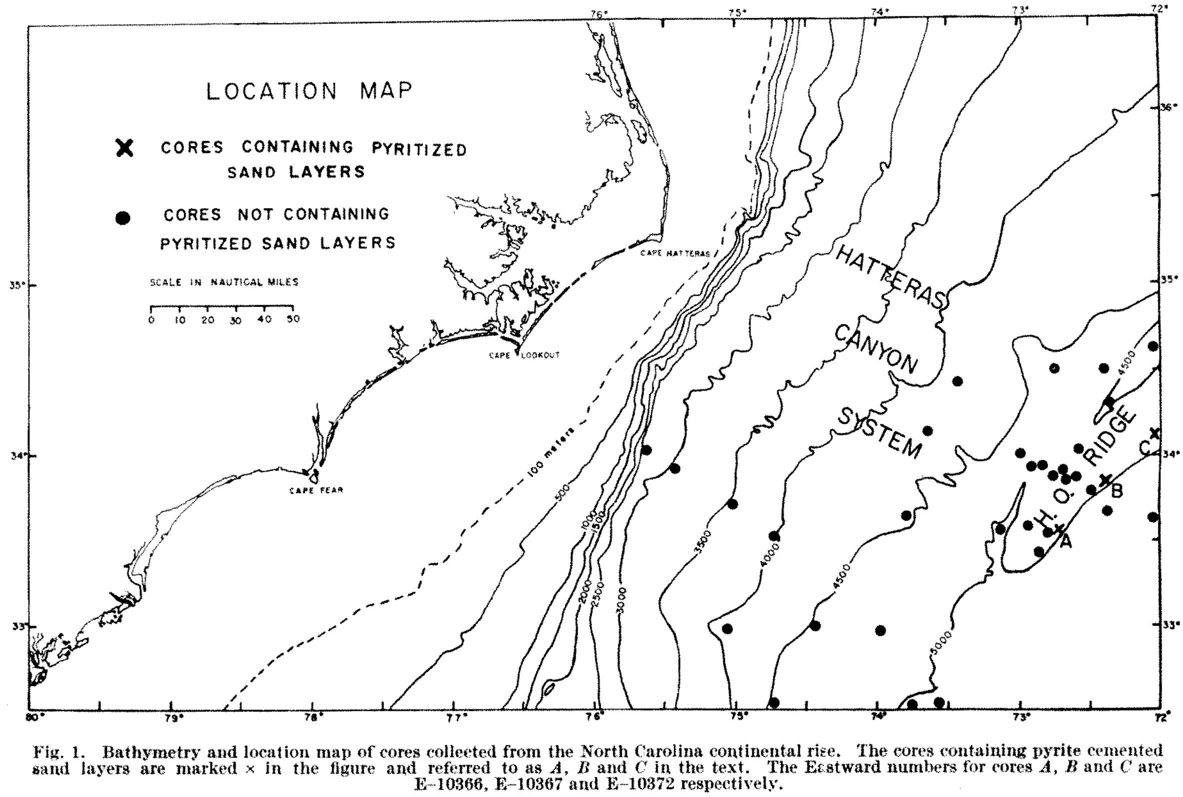

Fig. 1. Bathymetry and location map of cores collected from the North Carolina continental rise. The cores containing pyrite cemented sand layers are marked × in the figure and referred to as *A*, *B* and *C* in the text. The Eastward numbers for cores *A*, *B* and *C* are E-10366, E-10367 and E-10372 respectively.

different stages of partial dissolution and subsequent replacement by pyrite. The few calcareous particles present in the pyritized sandstones are relatively coarse, and in view of the strong evidence of solution effects on these grains it is probable that finer calcareous material has already been selectively removed. Extensive solution of $CaCO_3$ is to be expected during authigenic formation of pyrite[2,3].

Of the thirty-five piston cores collected as part of a continuing study of the North Carolina continental rise, only three contain pyritized sandstone. All three are from the seaward flank of the Hatteras Outer Ridge (Fig. 1) and we propose that formation of the pyritized sand layers is related to the unique environmental conditions on the seaward flank.

Sediment is probably delivered to the outer ridge by both turbidity currents and southerly flowing bottom "contour" currents[4]. The turbidity flows emanate from the Hatteras Canyon System along paths controlled primarily by the Hatteras Outer Ridge[5]. A few turbidity currents cross the 400 m high ridge and deposit material on the seaward flank; most, however, are probably blocked or deflected by the ridge[5]. The ridge blocks most high velocity canyon flows by preventing them from reaching the seaward flank and thereby creating an overall low rate of sedimentation.

The few turbidity currents that cross the ridge carry both sands containing fauna from the continental shelf edge and fine grained, typically organic enriched[6], sediment from the continental slope[1,5]. Displacement of slope and shelf sediments to the outer ridge provides the relatively organic-rich fine grained sediment that generates sulphide as well as the clean sands which constitute a trap for the migrating sulphide. The unusual combination of typically organic-rich continental margin sediment deposited in rapid pulses but accumulating at overall rates slower than usual may be the important causative factors for extensive pyritization in the uppermost portions of the sediment column. The pyritized layers are also geologically significant because they must play a part in restricting and channelling vertical exchange between seawater and sediment as well as in interstitial water reactions and migrations. Although the layers of pyritized sandstones are thin and volumetrically unimportant in the local sediment column, the occurrence is of great interest because such cementation by pyritization is only the second known mechanism of lithification in the uppermost portions of deep sea sediments. Previously known deep sea lithification at shallow sediment depths[7] has involved cementation by $CaCO_3$.

We thank R. H. Berner and I. R. Kaplan for helpful comments; K. O. Rodolfo and J. Schlee for reading and criticizing our manuscript; I. G. Macintyre and R. D. Perkins for help in obtaining photomicrographs of the sandstones; and the Oceanographic Program of Duke University for use of the NSF supported research vessel Eastward. This study is one result of the joint Duke University–US Geological Survey programme in marine geology.

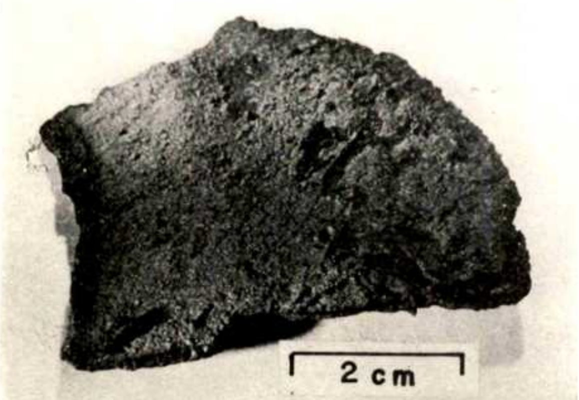

Fig. 2. Pyrite cemented sand layer taken from core *A* (E–10366) at a sediment depth of 540 cm. The uneven shape was caused by irregular fracturing during penetration.

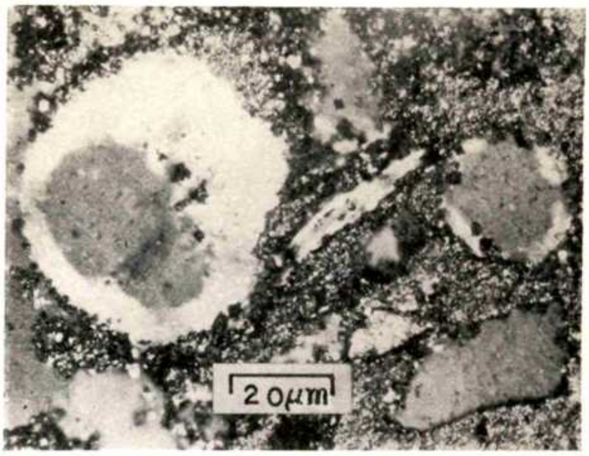

Fig. 3. Photomicrograph of thin section from the rock found in core *C* (E–10372) at a sediment depth of 870 cm, showing two partially dissolved planktonic foraminifera in pyrite cement. The right foraminifera shows more advanced stage of solution than the left.

Long-lived Thermal Structure under the Southern Rocky Mountains

HOT regions in the upper mantle can be located in two ways. The first is the classical technique of mapping heat flow through the crust from measurements at numerous points. The more recent method of geomagnetic deep sounding (GDS) uses recording magnetometers at a number of stations to locate regions of enhanced electrical conductivity in the Earth through the magnetic fields of transient currents. Some, at least, of the ultrabasic silicates of the mantle are semiconductors which show a sharp rise of conductivity[1] at temperatures above 1,000° C. While there is no one-to-one correspondence, it is probable that many of the known upper-mantle conductivity anomalies result from high temperatures. GDS is therefore an important means of seeking hot regions, hitherto limited by the small numbers of magnetometers available. Ocean floor spreading and plate tectonics have revolutionized earth science in the past few years. GDS affords means of extending study of the dynamic mantle demanded, especially under continents where little is yet known.

During 1967 we operated a roughly rectangular array of 42 three-component magnetometers[2] between latitudes

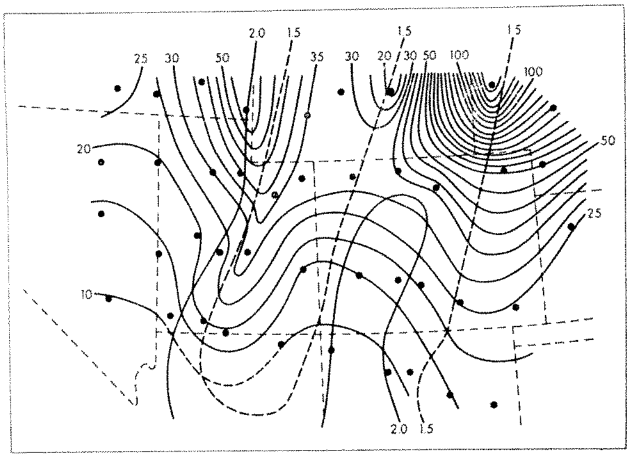

Fig. 1. Heat-flow isolines at 1·5 and 2·0 μcalories/cm^2 s from a provisional map by Roy, Blackwell and Decker (reproduced with their permission) with contours of Fourier spectral amplitude at $T = 60$ min of the vertical field Z of a substorm on September 1, 1967. Unit for Z is 0·1γ. Note tracking of high Z along the east flank of each heat-flow high, corresponding to currents under the heat-flow maxima. Dots represent variometers, straight broken lines outline Utah, Colorado and neighbouring states.

36° and 43° N and longitudes 101° and 116° W. The array locates transient electric currents within the Earth induced by external ionospheric currents during magnetic disturbances, and allows separation of the variation fields into parts associated with the external and internal currents. The analysis of magnetic fields of a polar substorm and of a storm, recorded during September 1967, has revealed two anomalies associated with transient electric currents in north–south conductors beneath the Southern Rockies in Colorado and beneath the Wasatch fault belt in Utah. The latter conductive structure seems to be continuous with that discovered by Schmucker[3] in southern New Mexico and the former is that discovered by Reitzel[4] in Colorado. The induction anomalies, identified by mapping amplitudes and phases of spectral components of the variation fields[5], are closely related to the pattern of heat flow through the crust of the Earth (personal communication from R. F. Roy, D. D. Blackwell and E. R. Decker) (Fig. 1). By using the array to separate the internal fields we have been able to propose[6] a model of highly conducting structures beneath this part of the United States to account for the induction anomalies (Fig. 2). While such models cannot be unique, ours has the advantage that the conductivity required (2×10^{-12} e.m.u.) is reasonable[7] for upper mantle material at 1,500° C, a temperature which is acceptable[8] at the 360 km depth of our conductor away from the anomalous ridges on its surface.

The GDS study is fully reported elsewhere[5,6]. Our purpose here is to show that the coincidence of the GDS and heat-flow anomalies means not only that the conductive structures related to the former are almost certainly thermal, but also that these parts of the upper mantle have been hot for a long time. Low thermal conductivities in the upper mantle and crust delay thermal information from depths of order 100 km for times of the order of 10^8 yr. A structure in the upper mantle responsible for both heat-flow and electromagnetic induction anomalies must have persisted for a time of this order, or else must have reappeared. The coincidence of heat-flow and induction anomalies greatly increases the probability that associated upper-mantle structures are old enough to be connected with the origins of overlying mountains and structural provinces.

Let t_h be the time required for a heat-flow anomaly to appear at the Earth's surface after a source appears in the upper mantle. As source one could, using numerical integration, take the whole surface S of the two-dimensional model whose cross-section is shaded in Fig. 2. Such a computation would be justified only if one knew more of the thermal conductivity in the upper mantle. We take a line source at the minimum depth of S; this gives a lower bound to t_h. Suppose a horizontal line source of heat appears at $t = 0$ at depth D in a semi-infinite medium, initially at zero temperature, of thermal diffusivity $\varkappa$ and whose horizontal plane surface is kept at temperature $\theta = 0$. If the line source produces heat at constant rate for all positive t, it can be shown by the method of images[9] that θ at depth d vertically above the line source rises as

$$\frac{\theta}{\theta_\infty} = \left[2 \ln\left(\frac{D-d}{D+d}\right)\right]^{-1} \left\{ Ei\left[-\frac{(D-d)^2}{4\varkappa t}\right] - Ei\left[-\frac{(D+d)^2}{4\varkappa t}\right]\right\} \qquad (1)$$

where $-Ei(-x) \equiv \int_x^\infty \frac{e^{-u}}{u}\,\mathrm{d}u$ and θ_∞ is the temperature after a very long time. With $\theta = 0$ at $d = 0$, heat flow through the surface will grow as θ at small d.

Of the two conductive ridges of Fig. 2 we choose that under the Southern Rockies, because the conductor and the heat-flow anomaly are symmetrical and because recent vulcanism complicates interpretation of the heat flow in Utah but not of that in the Southern Rockies. For D we take 210 km, the depth to the top of the conductive structure, and for $\varkappa$ 0·04 cm^2/s. The latter is too large for lattice conduction and is adopted to make allowance for possible partial melting; radiative transfer is probably unimportant below 1,500° C. The growth of the heat-flow anomaly due to the line source is shown in Table 1: that due to the real structure will grow more slowly. To estimate t_h one needs an estimate of the maturity of the anomaly, θ/θ_∞. If the surface of the conductor in Fig. 2 is an isotherm, the thickness of the overlying material is 210 km under the Southern Rockies and 360 km either side. The heat flow in the steady state should be somewhat less (because of the geometry) than 360/210, or 1·7 times greater under the mountains than

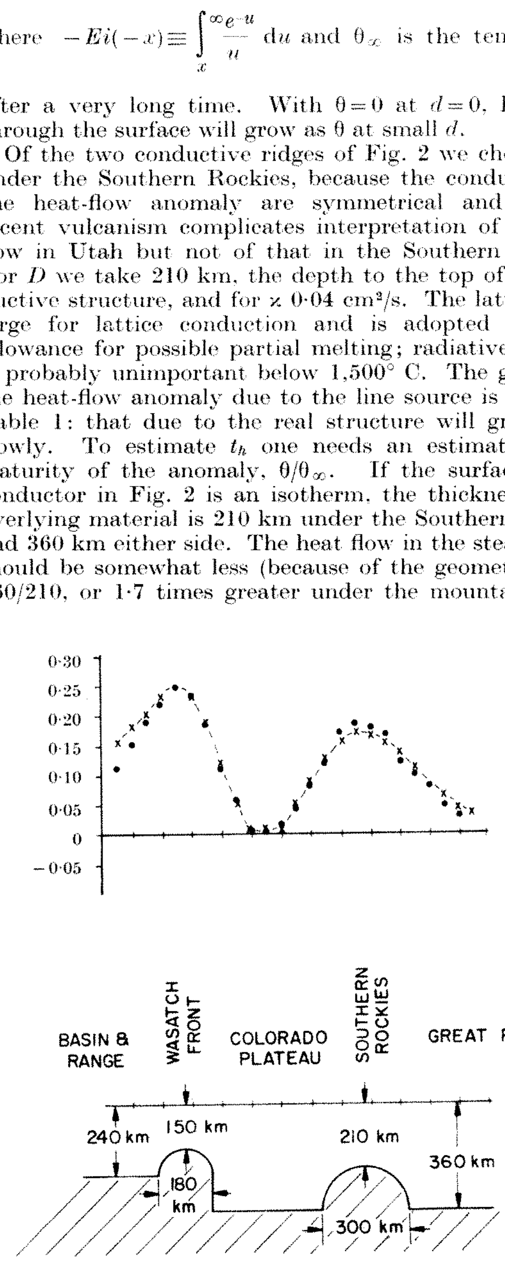

Fig. 2. Conductivity model approximating the eastward horizontal internal anomaly field Y_{ia}. The ordinate in the upper figure gives Y_{ia} expressed as a fraction of the east–west field which induces currents in the conductive structures. ×, Observed; ●, model.

in the plains. After correction for radioactive heat sources in the crust, the heat-flow data suggest a ratio[10] of about 1·4/0·8, or 1·75. It seems that the heat-flow anomaly has at least two-thirds of its final value. From Table 1 one finds that t_h exceeds 200 m.y.

Table 1. GROWTH OF THE ANOMALY IN TERMS OF θ/θ_∞

t(m.y.)	25	50	100	150	200	250	375	500	750
θ/θ_∞	0·035	0·176	0·418	0·559	0·646	0·705	0·792	0·841	0·893

This conclusion, of course, rests on the assumption that the heat-flow and induction anomalies both arise from the structure of Fig. 2. If their source is a shallower isothermal surface, or if friction at faults contributes significantly to the heat flow, the required age is reduced.

Gilluly's survey[11] of tectonic movements shows uplift in this part of the Rockies from about 300 m.y. ago, when the Ancestral Rocky Mountains were formed by virtually pure uplift, with effectively no compression or vulcanism, to about 220 m.y. ago; and again in Tertiary time between 70 and 20 m.y. ago, with the present Southern Rockies perhaps 15 m.y. old (personal communication from J. Gilluly). An underlying thermal structure 200 m.y. old may very reasonably be connected with these episodes of uplift.

The tectonics of the region abound in unanswered questions. Has North America overrun the East Pacific Rise, or has the latter started under the continent? How are mantle motions associated with spreading from the Atlantic and Pacific combined? We are concerned to show that, where induction and heat-flow anomalies have a common source in the upper mantle, such a source must have considerable age, and this places a boundary condition on the motions. Such a condition seems to apply to the Southern Rockies.

We thank Drs Roy, Blackwell and Decker for allowing us to publish a part of their provisional heat-flow contour map. The work discussed here is supported by the National Research Council and Defence Research Board of Canada, and by the US National Science Foundation.

New Canadian Cryptoexplosion Crater at Lake St Martin, Manitoba

LAKE ST MARTIN (51° 43′ N, 98° 30′ W) forms a broad shallow depression on nearly flat lying Palaeozoic carbonate rocks between Lake Winnipeg and Lake Manitoba. The occurrence of crystalline Pre-Cambrian rocks, fresh looking vesicular volcanic rocks and extensive post-Palaeozoic gypsum deposits within an area of about 200 square miles on the north side of the lake suggests that unusual structural complexities are present. The relations between these rocks are obscured by poor outcrop and extensive swamp, but a series of shallow bore holes in the anomalous area, together with re-examination of the surface outcrop, have recently made it apparent that they are the surface expression of a resurgent cryptoexplosion crater of Permian or Triassic age.

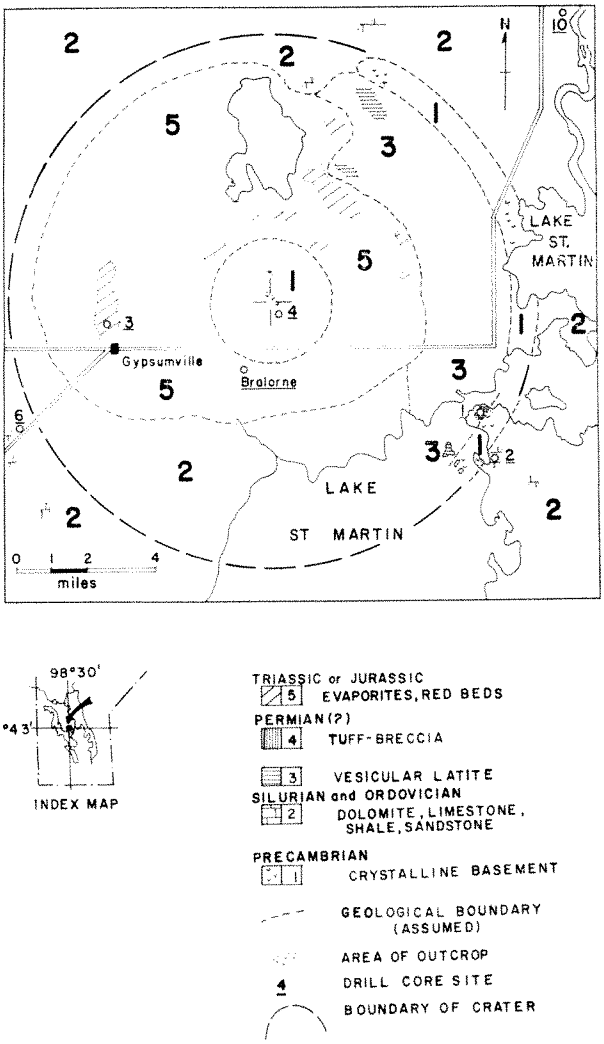

Fig. 1. Geology of the Lake St Martin region.

The geological data for this region are summarized and interpreted in Figs. 1 and 2. Although the data are quite inadequate to fix the structural details, they suggest a central core of crystalline Pre-Cambrian rocks, surrounded by a shallow annular basin of gypsum resting on fragmental rocks of Permian age, which grade outward into near massive igneous latites. In the outer parts of the structure, these rest on disturbed Palaeozoic carbonate rocks, but no Palaeozoic section seems to be present in the central part of the structure. An uplifted "rim" is present around the igneous rocks, locally exposing Pre-Cambrian rocks.

The central Pre-Cambrian core was sampled both in surface outcrop and in bore hole LSM-4 which penetrated 395 feet of similar rocks. The rocks are principally hornblende augen gneiss and granite gneiss, with dikes of spectacular graphic pegmatites. Despite contortion the rocks are little brecciated, and gneissosity is preserved. Pseudotachylite and breccia veinlets up to 4 inches wide occur locally.

Shock metamorphic phenomena are present in all specimens from this core. Quartz is intensely cleaved, and in thin section shows abundant deformation lamellae.

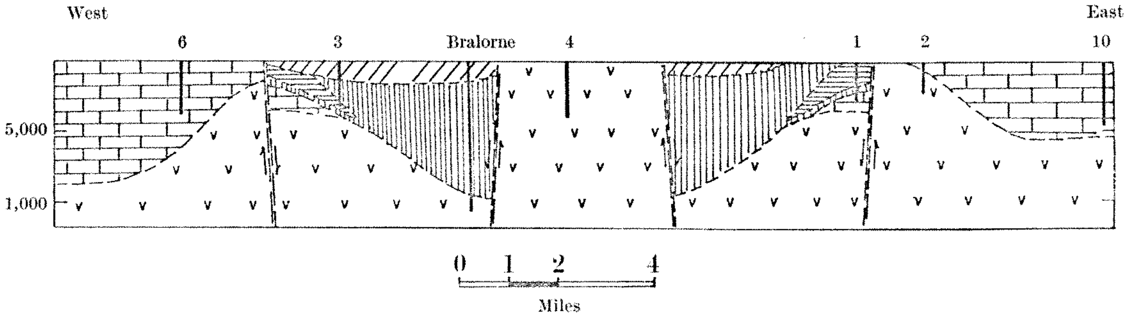

Fig. 2. E–W section across the region of Fig. 1. Vertical exaggeration 14 : 1.

mainly basal but with subordinate omega and prismatic lamellae. As many as five sets of lamellae occur on a single grain. Plagioclase is composed of amoeboid patches interspersed with very fine grained material. Composition, determined by refractive index of fused fragments, varies from An 28 to 40. The optic angle is anomalously small, ranging from 45° to 70°, and refractive indices and birefringence are anomalously small on many grains. Many grains show extreme undulatory or patchy extinction and sinuous patches of maskelynite ($n = 1{\cdot}524$–$1{\cdot}530$). Albite twinning is very rare and, where present, one set of twins is almost invariably isotropic. Amphibole varies from the original green hornblende to a reddish brown material with anomalous brownish interference colour. Birefringence varies from 0·027 to 0·004, and extinction angles from 0° to 12°.

The most contorted rocks consist of very fine grained yellowish schliers, suggesting threads of devitrified glass. Small amounts of clear glass with refractive index near 1·485 (lechatelierite ?) are present in some specimens. Many of the other specimens have an irregular brownish tinge due to partial alternation to analcite and thompsonite.

The Bralorne well, collared 1·8 miles from LSM-4, returned short sections of 4 inch diameter core from depths of 400–1,055 feet. Grey breccia containing fragments of granitoid rocks and very rare fragments of aphanitic purple, igneous rock in a gritty tuffaceous matrix is at least 800 feet thick. It seems to rest on argillized but unshocked granodiorite intruded by stringers of aphanitic igneous rocks. No section of evaporites or Palaeozoic carbonate rocks was penetrated. Fragments in the breccia from the Bralorne well do not display shock phenomena; many are remarkably fresh, suggesting that they are not derived from the altered granodiorite immediately below.

Bore hole LSM-3, collared 4·2 miles west of LSM-4, penetrated 189 feet of sedimentary rocks with gypsum at the top, passing downward into shale and sedimentary breccia which in turn lies with sharp contact on altered polymict breccia containing glassy fragments in a fine clastic matrix (suevite). 96 feet of this breccia is present, grading in the lower 20 feet into an aphanitic purple latite of igneous appearance. This igneous rock with rare small inclusions extends from 265 feet below surface to the bottom of the hole at 299 feet.

Bore hole LSM-1, situated 5·9 miles south-east of LSM-4, passed through 213 feet of remarkably homogeneous, dense, purple, aphanitic latite. Inclusions became common toward the base, and at the base 10 feet of brecciated, rotten, intensely altered, plastically contorted granite are present. The bottom 62 feet of this core consist of sedimentary breccias interbedded with red shale and grey carbonates. Basement fragments are common in the breccias, occasionally with contorted shapes and slight shock metamorphism, but the principal fragments are contorted, discoloured carbonates. The disturbed sedimentary rocks slightly resemble those of the surrounding Ordovician–Silurian carbonate section, but are severely brecciated and altered. They may be part of a Palaeozoic section not preserved elsewhere in this region.

Outcrops of igneous rocks similar to those in LSM-1 occur on an island in Lake St Martin and east of Gypsum Lake. Abundant large vesicles are commonly oriented and indicative of flow. In most observed cases the indicated flow direction was nearly horizontal, but several regions of steep dips, suggestive of fissure vents, were observed. Age determination by the whole rock K/Ar method yields ages of 225 ± 50 m.y. for these rocks[1].

Fresh, unshocked, near-massive granodioritic rocks outcrop intermittently along an arc from east of Gypsum Lake to the east shore of Lake St Martin. Associated with these outcrops of basement rocks are areas of abnormally uplifted Palaeozoic sedimentary rocks. At the site of drill-hole 2 (6·9 miles south-east of LSM-4), the carbonates are uplifted 600–700 feet above their normal position. Drill-hole 6 (7·5 miles south-east of LSM-4) possibly passes through structurally high carbonates as well, but at points as remote from the structure as drill-hole 10 (12 miles north-east of LSM-4), the sedimentary section is normal.

If the curved structural high represented by the Pre-Cambrian outcrops is assumed to be part of the rim of a circular structure, geometric projection from the three main areas of fresh crystalline Pre-Cambrian rocks defines the centre and radius of the area. The results are shown in Fig. 1, and give a diameter of almost exactly 12 miles. The centre falls almost on the site of LSM-4. The diameter of the central mass of shocked Pre-Cambrian rocks cannot be greater than 2·5 miles, and may be less.

The Lake St Martin structure seems to be a typical Canadian cryptoexplosion structure of the resurgent type[2]. Two novel features, however, are displayed: the crater occurs within flat-lying Palaeozoic sedimentary rocks, and a post-crater sedimentary fill is preserved. Canadian craters tend to fall along linear belts uplifted in late Palaeozoic or Mesozoic time[2]. The Lake St Martin structure lies almost precisely on this space–time line but, for reasons unknown, erosion has not yet stripped away the surrounding Palaeozoic rocks as it has at other Canadian craters. The preservation of the gypsum may also be attributed to slight erosion. Gypsiferous crater fills are known in the simple craters Brent and Deep Bay[2], but hitherto no resurgent crater had been discovered which was so pristine that the crater fill was preserved. Erosion of the Lake St Martin structure has apparently been slight. Further deep drilling at the site should produce significant new information on the superstructure of resurgent craters.

Lake St Martin is the third crater the location of which along "welts" on the Pre-Cambrian shield was predicted before discovery (the others being Charlevois[3] and Mistastin Lake[4]). The probability that three structurally and petrographically unusual craters would appear at the predicted sites in the course of less than 100 m.y. as the result of random impact of cosmic missiles seems negligible.

I thank H. R. McCabe and B. B. Bannatyne, Manitoba Department of Mines and Natural Resources, who

arranged access to the outcrops and drill cores, and provided maps and information on the area.

Composition of some Aluminium Silicate Bearing Contact Rocks from County Donegal, Eire

THE wide occurrence of the three aluminium silicate minerals andalusite, kyanite and sillimanite either individually or in pairs, or sometimes all together in metamorphic rocks[1,2], makes the study of these minerals attractive to petrologists and experimentalists because their presence and associations may be used to delineate the temperature and pressure range of a given metamorphism.

The aureoles associated with the granite plutons of Donegal[3] present a unique opportunity for a study of these polymorphs in the field, particularly because the Donegal area has been investigated in great detail by many workers[4]. The aureoles contain all the polymorphs in various combinations and previous workers in this area have regarded the presence of a particular aluminium silicate or association of the polymorphs to indicate certain limits to the pressure operating during metamorphism. For example, the presence of kyanite in the deformed aureole of the Main Donegal Granite has been taken[3] to indicate that high pressure prevailed. Some undeformed aureoles, which carry andalusite, were thought in contrast to have formed at lower pressures. The role of rock composition was not seriously considered, although Pitcher and Read did suggest that andalusite may be confined to pelites of a particular composition.

Analyses of eighty aluminium silicate bearing pelitic rocks from five of the Donegal aureoles[5] show a remarkable distribution with regard to the aluminium silicates present (Fig. 1). Kyanite-containing rocks have a restricted bulk composition. This mineral is limited to those rocks with magnesium/magnesium + iron ratios greater than about 0·5, while rocks containing andalusite, fibrolite and sillimanite in all possible combinations have unrestricted compositions within the compositional range studied.

Further, new textural and spatial data on the minerals from different aureoles clearly show that the crystallization sequence is kyanite, andalusite, fibrolite, coarse sillimanite[5]. These data are interpreted in terms of a series of overstepping reactions which take place with increasing temperature. The reactions are continuous and no reaction occurs between earlier and later aluminium silicates, all of which develop directly from the groundmass. The presence of more than one polymorph in the same rock is therefore the result of metastable persistence. Not all the rocks show the whole sequence and individual aureoles or parts of an aureole may show only the assemblages formed by one of the reactions.

The first reaction produces kyanite in the relatively magnesium-rich rocks of the Ardara and the Main Donegal Granite aureoles and staurolite in the iron-rich rocks; these latter do not contain kyanite. Later reactions in all the rocks can produce andalusite, fibrolite and sillimanite; they do not involve the formation of an iron-rich phase such as staurolite and occur in rocks showing the whole range of magnesium–iron values found. The actual assemblages seen in a given aureole are complicated by the overstepping which may be marked or limited, depending on the heating characteristics of that aureole. The first reaction is particularly prone, as one might expect, to considerable overstepping so that in the extreme case the assemblages of the first reaction have been found in only one or two rock samples of a particular aureole.

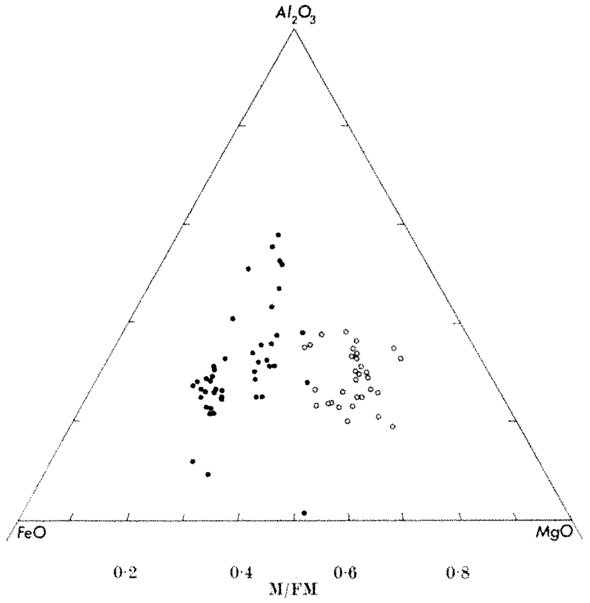

Fig. 1. Thompson AFM diagram of aluminium silicate bearing aureole rocks from County Donegal, Eire. ●, Kyanite free rocks; ○, kyanite bearing rocks.

It may be concluded that the absence of kyanite in some or part of one of the Donegal aureoles may be caused by (1) the lack of an appropriate rock composition—indeed, few pelites have the high M/FM ratio required; (2) the fact that the reaction producing kyanite was overstepped.

Either or both of these factors will result in rocks not containing kyanite, in spite of the fact that the rock may have crystallized in or passed through the stability field of kyanite. In contrast, the absence of sillimanite or fibrolite or andalusite in the Donegal aureoles usually results from the lack of the appropriate physical conditions.

Experimental Conversion of Biotite to Hydrobiotite

THE weathering of biotite in the soil frequently leads to replacement of interlayer K^+ by hydrated Mg^{2+}, with accompanying structural expansion along the *c* crystallographic axis from 10 to 14 Å (ref. 1). Usually, the 14 Å vermiculite phase becomes established without the development of well-defined intermediate spacings on the X-ray diffraction pattern. Biotite, however, sometimes weathers to hydrobiotite[2] in which there is a regular alternation of 10 Å biotite and 14 Å vermiculite units yielding distinct X-ray reflexions at 12 and 24 Å. Hydrobiotite may also originate, perhaps more frequently[3], through hydrothermal alteration. The vermiculitization of biotite in the laboratory has been extensively studied without observation of an intermediate regularly layered phase[4–6], although in one study[7] hydrobiotite was detected as a minor component. Complete regular interstratification has only been achieved by reversing the reaction so that vermiculite is converted to a mica-like phase by controlled sorption of K^+ and other ions[8–10]. We have now accomplished the transformation of biotite to hydrobiotite in conditions which throw some light on the mechanism involved.

Following a study of biotite weathering at Rehiran, Inverness-shire[11], which suggested that oxidation might play an important part in the transformation of biotite to hydrobiotite, vermiculitization of fresh Rehiran biotite with and without an active oxidizing agent was compared. Two 1 mg samples of biotite flakes (0·5 mm diameter) were immersed in 25 ml. 0·05 M $MgCl_2$ and two drops of bromine (35 mg) were added to one sample only. Both samples were shaken gently for 3 days and then individual flakes examined by X-ray diffraction. With $MgCl_2$ alone, distinct 14 and 10 Å reflexions were visible with no intermediate spacings. The oxidized sample, however, gave a strong line at approximately 12 Å and, for some flakes, a weaker reflexion at 24 Å, indicating hydrobiotite formation. Similar results were obtained using 5 mM $MgCl_2$, but with a 0·5 M solution strong reflexions at 12 Å and 14 Å were found for oxidized samples.

These results indicate that the Rehiran biotite alters to hydrobiotite only when cation exchange proceeds in conjunction with active oxidation. Bassett[12] suggested that the formation of hydrobiotites would be explained if replacement of K^+ by hydrated Mg^{2+} led to strengthened K–O bonds in adjacent interlayers, but he was unable to suggest a mechanism for such a long range effect. A plausible mechanism is suggested by recent observations that K^+ is more firmly held by biotites which have been oxidized either thermally[13] or chemically[14]. Oxidation of the ferrous ions in the two silicate layers on either side of a hydrated interlayer should lead to stronger retention of K^+ in the two adjacent interlayers. Replacement of K^+ by the much larger hydrated Mg^{2+} complex requires considerable flexion of at least one of the adjacent silicate layers, so that random replacement of K^+ in interlayers within the body of a biotite flake will be inhibited by the inflexibility of the surrounding tightly bonded biotite layers. Thus formation of the regular hydrobiotite structure is likely to begin by replacement of K^+ round the edge of a surface layer of the biotite, and to proceed by attack on successive alternate interlayers.

The importance of ferrous iron oxidation in the origin of hydrobiotite is also indicated by the fact that hydrobiotites are frequently, if not always, highly oxidized[15,16]. Moreover, hydrophlogopite, a regularly interstratified Mg rich counterpart of hydrobiotite, has never been recorded as far as we are aware.

Proton Migration in Hydrogen-bonded Chains

Proton conduction in hydrogen-bonded substances has attracted attention because the observed mobilities are of a comparable order with the electronic mobilities in some semiconductors. Indeed, these materials have been termed protonic semiconductors[1]. The work in this area is motivated mainly by the interest in the proton in biological processes[1]. As the simplest structure in this group, ice with the H_3O^+ defect has been studied intensively[1–5].

Our purpose here is to suggest a possible analogy between the motion of protons in a hydrogen-bonded chain and the motion of dislocations in crystals[6]. This analogy focuses attention on the cooperative motion of many protons and raises the possibility that the actual energy barrier to this cooperative motion is far smaller than that faced by a single proton. In this preliminary examination of the problem, the model used for the hydrogen-bonded chain is kept as simple as possible in order to facilitate direct contact with available computations for the Frenkel–Kontorova dislocation model[7–9].

The model for the hydrogen-bonded chain consists of an infinite one dimensional chain of alternating atomic compounds *A* and ionized hydrogen atoms, similar to the

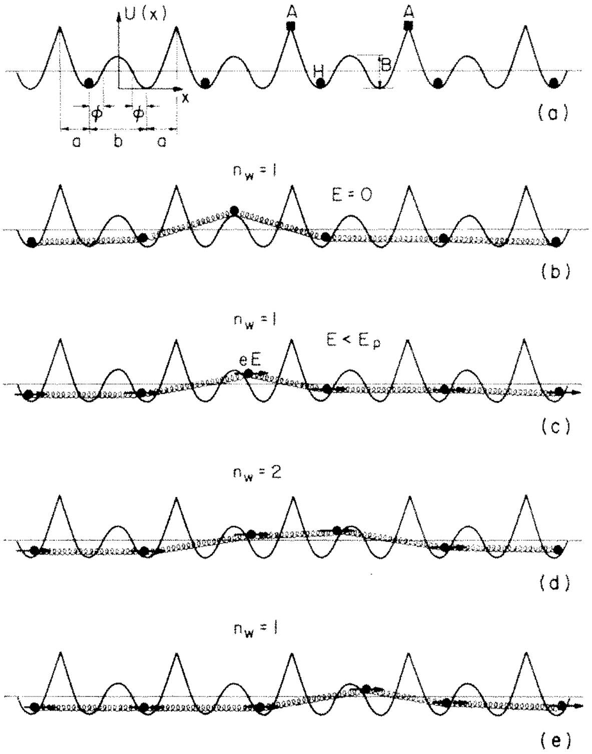

Fig. 1. Model for hydrogen-bonded chain A—H — — A—H — — ; (*a*) Defect-free chain. Horizontal line separates positive and negative curvature regions for $U(x)$. (*b*) Chain with inter-bond defect with no external field. (*c*) Same as (*b*) but with applied field $E < E_p$. Stable configuration. (*d*) Unstable configuration corresponding to conditions of (*c*). (*e*) New stable configuration with defect advanced one step.

one proposed by Fischer, Hofacker and Sabin[2]. This model may represent ice[2] (HO)-H, potassium phosphate[10] ($KHPO_4$)-H, isocytosine[11] ($C_4H_4N_3O$)-H, and so on. The asymmetric position of the protons in the chain of the form

——A–H——A–H——A–H——A–H——A–H——

or alternatively

——H–A——H–A——H–A——H–A——H–A——

is attributed to the existence of a double well potential for the protons; this potential is calculated for ice in ref. 2.

We consider the energy of interaction of the entire collection of A compounds, treated as unstructured points at positions $X_1, \ldots, X_N$, and protons at positions $x_1, \ldots, x_N$. By the Born–Oppenheimer approximation the energy of interaction V may be expressed as a function $V(X_1, \ldots, X_N; x_1, \ldots, x_N)$ which admits the two stable equilibrium configurations indicated above. We regard the positions of the A compounds, $X_1, \ldots, X_N$, as fixed at the equilibrium spacing. Then we postulate that we can write $V = V(x_1 \ldots, x_N)$ in the following form:

$$V = \sum_i U(x_i) + \frac{1}{2} \sum_{i,j} W(x_i, x_j)$$

That is, with the As fixed and uniformly spaced, the interaction energy is regarded as separated into two parts: (1) $U(x_i)$ which describes the interaction of the ith proton with all the As; (2) $W(x_i, x_j)$ which describes the pairwise interaction between the protons.

In order to make direct contact with the dislocation calculations of ref. 7, we assume the following form for $U(x)$, where each x_i is measured from the mid-point between two A locations (Fig. 1a):

$$\begin{aligned} U(x) &= \frac{1}{2} k_2\left(x - \frac{b}{2}\right)^2 & \frac{b}{2} - \varphi \leq |x| \leq \frac{b}{2} + a \\ &= \frac{1}{4} k_2 \varphi b - \frac{k_2 \varphi}{b - 2\varphi} x^2 & |x| \leq \frac{b}{2} - \varphi \end{aligned}$$

For the same reason the proton–proton interaction $W(x_i, x_j)$ is taken as nearest neighbour, corresponding to linear springs with spring constant k_1. By our method of model construction, these springs exert zero force when all the protons are equally spaced in corresponding wells as in Fig. 1a.

In order to introduce the proton defect, we assume that all the protons to the left of a point in the chain have moved into the right wells, but all the remaining protons are still in the left wells. Because of the proton–proton interaction $W(x_i, x_j)$, the equilibrium configuration of the protons will no longer lie at the bottom of the wells of $U(x)$ (Fig. 1b). The problem is now mathematically identical with the dislocation calculations of ref. 7. As shown there, in precisely two equilibrium configurations in this circumstance there will be either n_w or $n_w + 1$ ($n_w = 0, 1, \ldots$) protons in the central portion of $U(x)$ where its curvature is negative. The value of n_w depends on the parameters of the model. The equilibrium solution corresponding to n_w is stable; that corresponding to $n_w + 1$ is unstable. Put another way, the stable solution corresponds to the potential well and the unstable solution to the saddle point in a configuration space with dimension equal to the number of protons.

If an electric field E is applied, exerting a force eE on the protons, there will be again two equilibrium solutions (as shown in the corresponding dislocation calculation[7]), stable and unstable, corresponding to n_w and $n_w + 1$ respectively, provided $E < E_p$ where E_p is discussed subsequently.

The motion of the defect, according to this model, is shown in Fig. 1. In Fig. 1b the stable proton configuration is illustrated, with $n_w = 1$, under an applied field $E < E_p$. The corresponding unstable configuration, with $n_w = 2$, under the same applied field is shown in Fig. 1d. Fig. 1e then shows the defect advanced by one step to the next stable configuration with, again, $n_w = 1$.

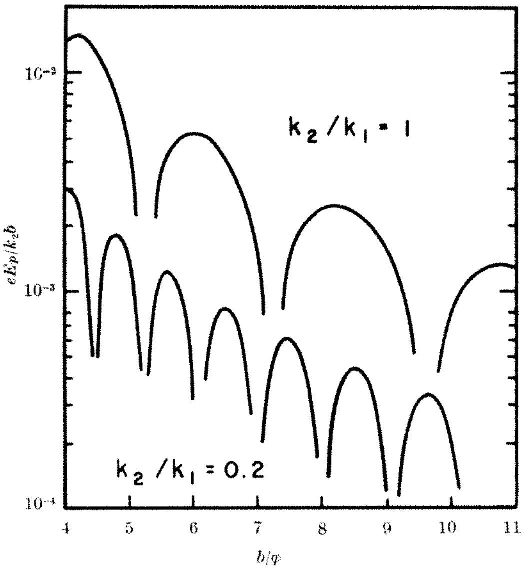

Fig. 2. Critical field E_p as function of b/φ (see Fig. 1) for $k_2/k_1 = 0{\cdot}2$, 1.

The critical field E_p corresponds to the Peierls stress in the dislocation literature[6] and it, along with all other quantities, may be computed explicitly for this model[7–9]. The results for E_p are shown in Fig. 2 for two sets of values of the model parameters.

As shown in ref. 7, the barrier height for the cooperative motion of the protons in this model under an applied field $E < E_p$ is

$$V(E) = B \frac{b}{\varphi} \frac{eE_p}{k_2 b} \left(1 - \frac{E}{E_p}\right)^2$$

where B is the barrier height of $U(x)$.

Fig. 2 shows that the activation energy for cooperative proton motion is several orders of magnitude smaller than B. In fact, for some values of b/φ, $E_p = 0$, and for these critical values there is no barrier to cooperative proton motion. If the protons are now regarded as in thermal equilibrium, the unidirectional transition rate is found, on the basis of a classical analysis[2], to be

$$\mathrm{f}(E) = \frac{(k_2/m)^{1/2}}{2\Pi} \nu e^{-V(E)/kT}$$

where $\nu = \nu(b/\varphi, k_2/k_1)$ is a coefficient of the order of unity. For weak fields, $E/E_p \ll 1$ and, considering the net flux in one direction, the mobility is found as

$$\mu = (\mathrm{f}_{\rightarrow} - \mathrm{f}_{\leftarrow}) \frac{b}{E} = \mathrm{f}(0) \frac{eb^2}{kT}$$

To estimate the transition rate and the mobility of protons in ice, the calculations and graphs given in ref. 2 are taken as the basis of the numerical values. From Fig. 3 of ref. 2, along with the assumption of Coulomb interaction between the next neighbour protons, we estimate

$k_1 = 2{\cdot}94 \times 10^4$ dyne/cm, $k_2 = 2{\cdot}60 \times 10^4$ dyne/cm, $\varphi = 0{\cdot}18$ Å
$b = 0{\cdot}78$ Å, $b + 2a = 2{\cdot}76$ Å, $B = 0{\cdot}0080$ a.u. $= 3{\cdot}47 \times 10^{-13}$ erg.

With the parameters $k_2/k_1 \approx 1$, $b/\varphi = 4{\cdot}3$, we find that $n_w = 1$ from Fig. 2. Then one has $eE_p/k_2b \approx 10^{-2}$ and computes $V(0) = 0{\cdot}0003$ a.u. $= 0{\cdot}13 \times 10^{-13}$ erg. In this case the potential barrier for cooperative motion is about thirty times smaller than the barrier B for individual proton motion. It should be noted that the calculated value of $V(0) \sim 0\cdot2$ kcalories/mole for the cooperative motion is much smaller than the activation energy for conductivity ($\sim 8\cdot5$ kcalories/mole). Thus the major portion of the latter is to be ascribed to dissociation energy, as noted previously[3,4,12]. Table 1 gives the results of the present analysis along with the available experimental data, and in parentheses, the values obtained using B instead of V. In calculating the conductivity $\sigma = qn\mu$, the value of n, the number of proton defects per cm^3, is taken as 10^{10} following ref. 5.

As we indicated at the outset, our purpose was to make direct contact with analogous dislocation calculations and the model has been drastically idealized for this purpose. In particular, the one dimensional representation does not include a mechanism, for example, by suitable defect motion, to reorient the bonds back to the original state to permit d.c. conductivity[13]. Furthermore, the strength of the H–H interaction has undoubtedly been overestimated. On the other hand, the restriction to nearest-neighbours interaction introduces an error which may be compensating. The results seem sufficiently encouraging to warrant further refinement of the model and also its analysis on the basis of quantum rate theory. Here the recent results of Weiner[14] and Weiner and Partom[15,16] may prove useful.

Table 1. RESULTS OF THE ANALYSIS

T (K)	f(s^{-1})	μ(cm^2 V^{-1} s^{-1})	σ(Ω^{-1} cm^{-1})	$\mu_{\rm exp}$	$\sigma_{\rm exp}$

Preferential Hg^{2}H Formation in the Quenching of Hg(6^3P_1) by H^{2}H

A. B. C. and Hedges[1] have described a technique of monochromatic flash spectroscopy in which an intense pulse of Hg 2537 Å radiation was generated with a microwave discharge. The light was absorbed in a reaction system containing Hg vapour with various quenching gases and transient species were produced at a sufficiently high concentration for their detection by kinetic absorption spectroscopy. We report here the discovery that monochromatic excitation can also be achieved with a specially designed, electroded flashlamp. The method is simple and highly practicable. We have achieved quantal absorptions two-fold greater than that of A. B. C. and Hedges, and the new technique can also be applied with very low pressures of reactants. The determination of the relative yields of mercury hydrides in the quenching of Hg(6^3P_1) by H_2, $^2H_2$ and H^{2}H is described to show application of the method; quenching by H^{2}H was found to produce Hg^{2}H preferentially and this observation indicates a possible mechanism for the reactions.

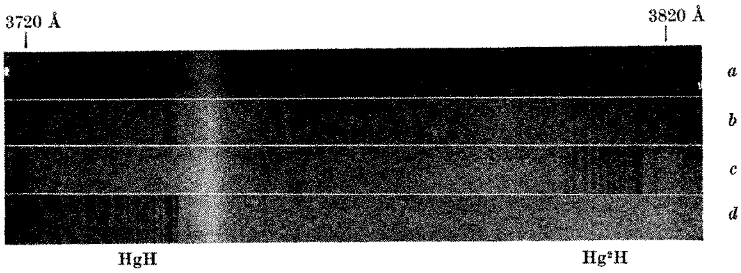

Fig. 1. Mercury hydrides in the reaction of Hg(6^3P_1) with (*a*) H^{2}H, (*b*) $H_2 + {}^2H_2$ (equimolar), (*c*) $^2H_2$, and (*d*) H_2. The (1,0) bands of the $A^2\pi$—$X^2\Sigma^+$ systems of HgH and Hg^{2}H. Each exposure at 16 μs and 300 J flash energy, $[H_2]+[^2H_2] = 2$ torr $+ [Ar] = 700$ torr.

If a flash discharge is made to occur simultaneously between many closely spaced electrode-pairs, we have found that the emitted light consists almost entirely of discrete lines with flash energies up to at least 500 J; the resonance transitions of atoms are intense. Apparently the electron concentration is low compared with that in a conventional flashlamp with a single pair of electrodes; the discharge is silent and of low overall luminosity. With an energy of 300 J per pulse, a plate exposed to fifty flashes showed no detectable background continuum. Optimization of most of the variables, for maximal absorption of the 2537 Å resonance line in a reaction volume, was achieved by constructing and testing various short flashlamps with four to eight electrode pairs. Thus the design of the apparatus, with which the absorption spectra of Fig. 1 were obtained, was realized.

The main body of the device was constructed from a 'Pyrex' tube, length 88 cm and diameter 5 cm. A quartz tube, diameter 1·5 cm, was positioned coaxially inside and was fixed to the 'Pyrex' with glass end-rings and an epoxy resin; the flash discharge was confined to the annulus between the tubes. Forty-four tungsten electrodes were sealed into opposite sides of the 'Pyrex' to form twenty-two opposing electrode pairs. To ensure simultaneous firing, each electrode was isolated with 1 m of coaxial cable[2,3]. The lamp was filled with Hg vapour and 1 torr of helium; it was powered with a 1·5 μF capacitor charged to 20 kV and triggered with a spark gap. The device behaves as an under-damped *LCR* circuit of period 12 μs, exponential half-life of 10 μs, and with a peak current of $\sim 1\cdot5 \times 10^4$ A. A reaction vessel of 5 mm internal diameter was placed coaxially inside the inner quartz tube; optical filters could be located in the intervening volume. The entire apparatus was mounted inside a large furnace and heated to 313 K ($Hg = 6 \times 10^{-3}$ torr) to obtain maximum absorption of resonance radiation. The quantal absorption per pulse was estimated as $1\cdot7 \times 10^{14}$ quanta cm^{-3}, by generating free methyl radicals in the reaction

$$Hg(6^3P_1) + CH_3N_2CH_3 \rightarrow Hg(6^1S_0) + 2CH_3 + N_2$$

The absolute [CH_3] was determined from the integrated absorption of the electronic transition at 2160 Å, for which the *f*-value is known[4].

The spectra of Fig. 1 illustrate the detection of mercury hydrides in the quenching of $Hg(6^3P_1)$ by H_2, $^2H_2$ and H^2H. The (1,0) bands of the $A^2\Pi-X^2\Sigma^+$ system are well separated and the preferential formation of Hg^2H in the quenching of $Hg(6^3P_1)$ by H^2H is clearly indicated. In the equimolecular mixture of $H_2 + {}^2H_2$, the yields of HgH and Hg^2H are approximately equal. Relative quantum yields for mercury hydride formation were measured by plate photometry and by determination of the Franck–Condon factors of the bands. Results are listed in Table 1, where the absolute yield of HgH in the reaction of $Hg(6^3P_1)$ with H_2 is the value recorded by A. B. C. and Hedges[5].

To investigate the initial quantum states of the HgH produced in the reaction of $Hg(6^3P_1)$ with H_2, experiments were conducted down to hydrogen pressures of 0·05 torr. Even at the shortest delay times of ∼7 μs, however, the HgH was detected only with zero-point vibrational energy.

Table 1. QUANTUM YIELDS OF FORMATION OF MERCURY HYDRIDE IN REACTIONS OF $Hg(6^3P_1)$

Reaction	Quantum yields
$Hg(6^3P_1) + H_2 \rightarrow HgH + H$	0·80 ± 0·10
$Hg(6^3P_1) + {}^2H_2 \rightarrow Hg^2H + {}^2H$	0·96 ± 0·10
$Hg(6^3P_1) + H^2H \rightarrow HgH + {}^2H$	0·14 ± 0·02
$Hg(6^3P_1) + {}^2HH \rightarrow Hg^2H + H$	0·80 ± 0·10

The results of Table 1 can be qualitatively understood if it is postulated that $Hg(6^3P_1)$ reacts with H_2 by first inserting between the H atoms to form an electronically excited H HgH*. The excited intermediate subsequently "predissociates" by crossing to a second state of H HgH which correlates with and dissociates to the ground states of HgH + H.

$$Hg^* + H2 \rightarrow H\ HgH^* \text{ (insertion)}$$
$$H\ HgH^* \rightarrow H\ HgH \text{ (crossing)}$$
$$H\ HgH \rightarrow HgH + H \text{ (dissociation)}$$

Predissociation could favour ejection of the lighter H atom in the quenching of $Hg(6^3P_1)$ by H^2H. Such a scheme can therefore account for the non-statistical Hg^2H yield in the H^2H reaction, for the non-statistical total yields of the hydrides and for their apparent production with very little excess vibrational energy.

Extensions of the same experimental method to monochromatic flash spectroscopy with the resonance radiations of cadmium[6], xenon and krypton[7] have been described.

We thank the Science Research Council for equipment grants.

Constant-Wave Laser Oscillation in a Carbon Monoxide Chemical Laser

CW laser oscillation has been observed on twenty-eight vibration–rotation transitions in the range 5·22–5·55 μm with a CO chemical laser. This is the first report of purely CW lasing in chemically excited CO, although we have previously[1] announced a "quasi-CW" laser of this type in which the duration of the laser pulse is longer than the characteristic decay time of excited CO. We give here the resolved laser spectra and show that long term CW operation can be achieved in a CO chemical laser with rather modest requirements for pump speed and input energy.

The reactions believed responsible for the excitation of CO are

$$O + CS_2 \rightarrow CS + SO + 32 \text{ kilocalories/mole} \quad (1)$$

$$O + CS \rightarrow CO + S + 75 \text{ kilocalories/mole} \quad (2)$$

The excitation mechanism in the CO chemical laser has been controversial[2-4], but Hancock and Smith[5] seem to have confirmed the likelihood of reactions (1) and (2) by studying directly the excitation of CO in these reactions. The fast reaction:

$$S + O_2 \rightarrow SO + O \quad (3)$$

is crucial to the operation of the flash photolysis CO laser and also contributes to generating oxygen atoms. A detailed analysis of the chemistry of this system will be given in a later paper.

The experimental arrangement is shown schematically in Fig. 1. Oxygen atoms were generated by passing a mixture of He and O_2 through a 60 Hz discharge produced with a neon sign transformer rated at 12 kV, 60 mA, controlled by a variable transformer. The atoms were rapidly drawn into the optical cavity where they were allowed to react according to reactions (1) and (2). The reaction products were extracted by a mechanical pump with a rated displacement of 500 l./min. The reaction products were non-corrosive and no special care was necessary except regular changing of pump oil and proper exhaust ventilation. The optical cavity consists of two internal gold-coated mirrors spaced 55 cm apart. One of the mirrors is flat and the other is spherical with radius $R = 230$ cm. The active length is 15 cm long with an internal diameter of 10 mm. Radiation was coupled out through a 0·5 mm hole in the centre of the flat mirror. Output was detected with a cooled (77 K) InSb photovoltaic detector chopped at 500 Hz. The laser spectrum was measured with a 0·5 m Jarrell–Ash spectrometer calibrated in high order with lines from a mercury lamp. Resolution of 0·6 cm^{-1} was obtained with 100 μm slits and a grating blazed at 7·5 μm.

Twenty-eight lines were observed and assigned to *p*-branch transitions in the CO molecule (Table 1). The constants used in computing the theoretical values of the

transitions are taken from ref. 6. Individual lines were quite unstable because the Doppler linewidth and the spacing between adjacent longitudinal modes are comparable for the experimental conditions listed here. Quite often, one mirror had to be tuned so that a cavity resonance would lie under the fluorescent line, making it impractical to scan the spectrometer. Spectra were recorded by advancing the spectrometer in steps of 0·5 cm⁻¹ and tuning the cavity for maximum output at each spectrometer setting. The region 5·0 to 5·6 μm was investigated and it is possible that a few transitions in this range were suppressed because of failure to satisfy the cavity resonance condition.

In optimum conditions, a total CW output of the order of 1 mW was obtained. This required an input of approximately 400 W into the oxygen dissociator. No effort was made to cool the walls of the laser tube although they became quite hot (~80° C) during operation, because of the chemical reaction. Thermal tuning of the optical cavity and mechanical vibrations are responsible for a slight instability in the total output. Although the total output of the laser was rather stable, individual lines were affected strongly by the thermal tuning caused by the cavity resonance conditions mentioned above.

The output power seems to be limited only by the oxygen atom flow rate. The oxygen atom flow rate was determined from a gas phase titration[7] with NO_2 at the reactant inlet and was found to be $\sim 2\times10^{-4}$ moles/s. In optimum lasing conditions, p (He) $\simeq$ 10–15 torr and p (O_2) $\simeq$ 1 torr. The NO_2 flow rate was measured with a calibrated flowmeter.

By using more efficient coupling, more effective oxygen atom production and transverse flow, significant increases in the output power are envisaged.

We thank the members of the Electro-Physics Laboratory and Professor J. T. Yardley for help. The research was supported by a grant from the US National Science Foundation, and equipment was obtained through the University of Illinois Industrial Affiliates Program on Physical Electronics.

Anodic Reactions of the Hydrogen Electrode

EXTENSIVE studies have been made of the cathodic reactions of the hydrogen electrode (see reviews[1,2]) but relatively few observations have been made in anodic conditions[3–5]. One reason why the anodic reactions of the hydrogen electrode received little attention

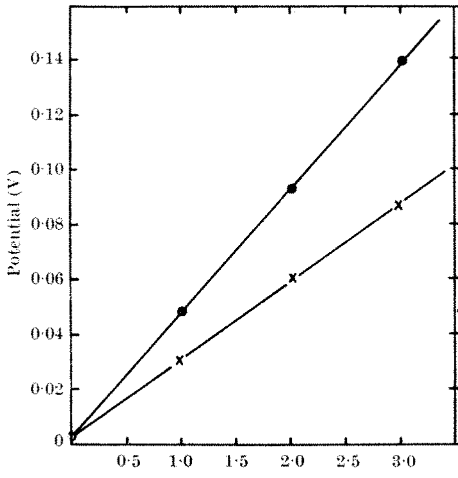

Fig. 1.

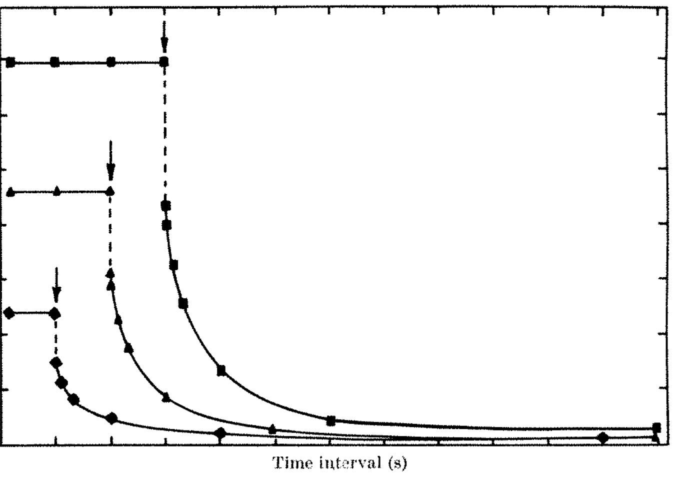

Fig. 2.

Fig. 1. Potential of hydrogen electrode at various current densities at 60° C. ●, Observed potential; ×, observed potential minus resistance polarization.

Fig. 2. Decay of potential on interrupting the current at the hydrogen electrode. Arrows indicate current interrupted; – – – –, instantaneous decay; ◆, 1·00 mA mm⁻²; ▲, 2·00 mA mm⁻²; ■, 3·00 mA mm⁻².

was that hydrogen electrodes which would support substantial anodic currents were not available. More recently, however, the interest in fuel cells has stimulated the development of electrodes that could maintain large currents in these conditions and as a result the anodic properties of the hydrogen electrode have been elucidated.

Studies of the cathodic reactions of the hydrogen electrode invariably concluded that the overpotential was related to the logarithm of the current, and this well-known "Tafel" relationship has become the basis of modern electrochemical theory[6]. In contrast the more recent work with hydrogen fuel cell electrodes[7-10] showed that in anodic conditions there was a linear relationship between the potential and the current. This linear relationship may be a result of the resistance component of the overpotential, which would be directly proportional to the current, being so large as to mask the true relationship for the reaction overpotential. To establish whether this linear relationship is characteristic of the electrode reaction it is thus necessary to determine the relationship between the potential and the current when the resistance component has been eliminated. At the same time it should be appreciated that these characteristics of fuel cell electrodes can only contribute to an understanding of the kinetics of the anodic reactions of hydrogen electrodes if the fuel cell electrodes are truly reversible hydrogen electrodes.

We have attempted to resolve the situation in the case of fuel cell electrodes consisting of palladium (3 per cent) supported on active carbon bound with PTFE[11]. The resistance polarization at 60° C of a circular electrode (3 mm × 57 mm in diameter) was readily measured in potassium hydroxide (8 M) by interrupting the polarizing current at different potentials and observing the decay of the potential on an oscilloscope. The results are summarized in Figs. 1 and 2, which show that the resistance of the electrode system accounted for about 30 per cent of the total polarization; the dotted line in Fig. 1 shows that the resistance free polarization is linearly related to the current density.

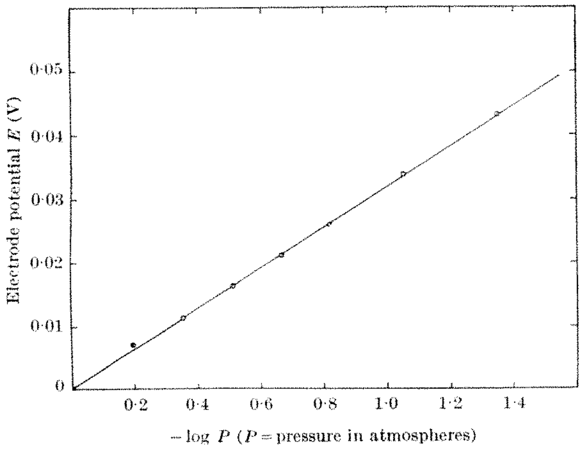

Fig. 3. The effect of hydrogen pressure on a fuel cell electrode at 25° C. ———, Theoretical line $E = -0.030 \log P$; ○, experimental points.

The reversibility of fuel cell electrodes was tested by ascertaining whether the open circuit potential was related to the pressure of hydrogen according to the Nernst equation. This was possible with an apparatus used in other studies of anodic reaction of the hydrogen electrode[12]. The results are shown in Fig. 3, where the open circuit potential is plotted against the logarithm of the hydrogen pressure. It can be seen that the results are in good agreement with the theoretical line.

It can thus be concluded that fuel cell electrodes of the type used in these experiments behave as reversible hydrogen electrodes and that in anodic conditions the potential is linearly related to the current.

Low-cost Oxygen Electrode Material

There is at present great interest in high energy density batteries, especially for use in urban transport[1]. For this application an electrically rechargeable system would be ideal, and night charging would assist in levelling out the demand for electricity. Metal-air batteries (notably zinc-air) are probably nearest to practical usefulness, but one limitation to their large scale use is the fact that a noble metal catalyst (usually platinum) may need to be used in the air electrodes, which have to reduce oxygen from the air to OH^- ions in the concentrated alkali electrolyte and subsequently to act in reverse for recharging. I report here preliminary tests in which lanthanum cobaltite—a semiconducting oxide—has given results comparable to those produced by platinum. The material clearly deserves detailed further attention and, after discussion of the results, suggestions are made for its development into a practical electrode.

The activity of lanthanum cobaltite ($LaCoO_3$) has been discovered during an investigation of semiconducting oxides as potential oxygen electrode materials. Attention has concentrated particularly on oxides with high conductivity ($> 10^3$ Ω^{-1} m^{-1}) to permit the use of a bulk electrode of an active material. Such a form would be ideal as it should have lower manufacturing costs than a thin-layer hydrophobic construction, and it would minimize any corrosion problems.

The oxides have been examined as 6 mm diameter rotating disk electrodes, chiefly at room temperature, with an automatic potential sweep rate of 12 mV/min. With a planar rotating electrode rather than a more practical arrangement, only small currents are obtained, but there is no possibility that the lack of activity of an electrode may result from too small an effective surface area.

So far NiO, CoO, SnO_2, In_2O_3, $LaCrO_3$, $LaCoO_3$, $PrCoO_3$ and $SrMoO_4$ have been examined, all but $SrMoO_4$ doped with aliovalent impurities. Only the cobaltites have given encouraging results, and $LaCoO_3$ is to be preferred to $PrCoO_3$ because of the much higher cost of praseodymium compounds. The conductivity of $LaCoO_3$ doped with strontium or nickel can be made greater[2] than 10^4 Ω^{-1} m^{-1}, and the material is stable in alkali although it dissolves readily in acid. A typical polarization curve of lanthanum cobaltite doped with 20 mole per cent Sr ($La_{0 \cdot 80}Sr_{0 \cdot 20}CoO_3$) is given in Fig. 1, which compares it with curves for a

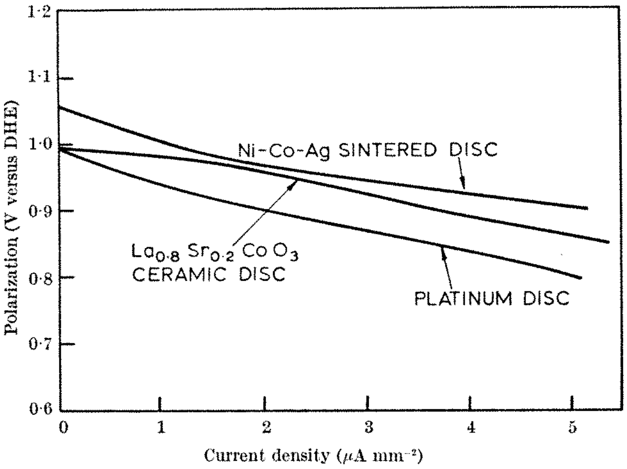

Fig. 1. Oxygen reduction in 5 N KOH solution at 25° C for $La_{0\cdot8}$ $Sr_{0\cdot2}CoO_3$ ceramic, Ni–Co–Ag metal sinter, and platinum sheet (rotating electrode speed 1,500 r.p.m., voltage sweep 12 mV min⁻¹).

platinum disk and for a porous metal sinter of Ni, Co and Ag developed at CERL by Hart and Wrench (private communication). At a given geometric area current density, the polarization of all three systems is similar. The results are not always completely reproducible, possibly because of impurities in the solution, but appreciable activity is always obtained. The metal composition has already been developed with simple manufacturing techniques into a practical porous sinter, from which adequate current densities are obtained.

Both strontium-doped and nickel-doped lanthanum cobaltite give high activity, so the activity is unlikely to be a direct effect of the impurity, especially because the strontium and nickel substitute for the lanthanum and cobalt respectively. Moreover, because $PrCoO_3$ too is very active whereas $LaCrO_3$ is not, even though, like $LaCoO_3$, they have the perovskite structure, the activity seems to be a particular attribute of the cobalt ions. (It is noteworthy that the metal sinter also uses cobalt as an active element.) There are two immediate differences between $LaCrO_3$ and $LaCoO_3$ which may be important in determining that $LaCoO_3$ is active:

(*a*) Whereas $LaCrO_3$ shows only *p*-type conductivity, $LaCoO_3$ can easily be made either *p* or *n*-type and also has a band gap[2] of only 0·30 eV. This amphoteric behaviour and narrow band gap may aid the absorption of oxygen and the subsequent release of ions. The electron mobility in $LaCoO_3$, however, is only one tenth that of the holes[2], and less impurity can be substituted (Gerthsen and Hardtl[3] reported that the solubility of thorium is only 4 per cent), so that the attainable conductivity is much lower. Within these limitations the extension of the measurements into the *n*-type regime will be very valuable.

(*b*) $LaCrO_3$ is antiferromagnetic, with a Néel temperature of 320 K; $LaCoO_3$ shows no long range magnetic order, but its detailed magnetic structure is still under discussion[4]. Winter[5] has attributed an improvement in the chemisorption of oxygen on to nickel oxide at high temperatures to the fact that the material is then above its Néel temperature. $LaCrO_3$ certainly becomes more active above its Néel temperature, but it is not yet clear whether this increase can be correlated with the magnetic transition.

In large quantities the material cost of doped $LaCoO_3$ is about £2 per kg. Further reduction in material costs would be achieved if "technical grade" ceria could be substituted for pure lanthanum oxide, for it contains 23 per cent La_2O_3 as well as 45 per cent CeO_2 and 18 per cent Nd_2O_3, with the balance comprising other rare earths. All rare earth cobaltites have the perovskite structure[6], and technical grade ceria should therefore be effective in making a practical electrode, in which case it would halve the materials' cost. Two main methods of electrode manufacture are being considered: thin porous plates, and a fine particle form for use in hydrophobic electrodes. There are various techniques for producing fine particle sizes[7], such as precipitation from aqueous solutions of the salts, or freeze drying (see, for example, ref. 8), which is becoming a powerful technique for catalysts.

In conclusion, $LaCoO_3$ deserves further detailed attention, both for its technical development into a practical electrode, and also because its electrical properties make it a unique material for investigating the basic processes of oxygen reduction.

Comments on "The Flow of Non-Newtonian Fluids under a Varying Pressure Gradient"

Barnes, Townsend and Walters[1] have communicated some results concerned with the pulsating flow of a non-Newtonian fluid through a pipe, in which it was shown that the mean pressure gradient along the pipe axis in pulsating flow conditions can be less than the constant gradient in conditions of steady flow, and it is suggested that this may be of industrial importance.

The driving pressures required for transporting fluids considered by the above authors are moderate and introduce no technological difficulties. It is much more important to find out whether there is an economic advantage to be gained with pulsating flow, and this is a different problem.

Thus if the flow rate Q is given by

$$Q = Q_m + Q_1 \cos \omega t \tag{1}$$

and the pressure gradient by

$$P = P_m + \sum_{n=1}^{N} P_n \cos (n\omega t - \varphi n) \tag{2}$$

then the pumping power is equal to

$$P_m Q_m + \frac{P_1 Q_1}{2} \cos \varphi_1 \text{ (unit pipe length)} \tag{3}$$

while the transport energy per unit volume of fluid is equal to

$$P_m + \frac{P_1 Q_1 \cos \varphi_1}{2Q_m} \tag{4}$$

In some cases the second term in equations (3) and (4) may be significant. Furthermore, even when power would be reduced or energy saved by oscillatory pumping it is, of course, worthwhile to adopt this technique only if the additional cost of the oscillatory equipment is not too large, as Fig. 1 indicates. Preliminary investigations have already been made by Harris[2] in which results of the type communicated by Barnes, Townsend and Walters

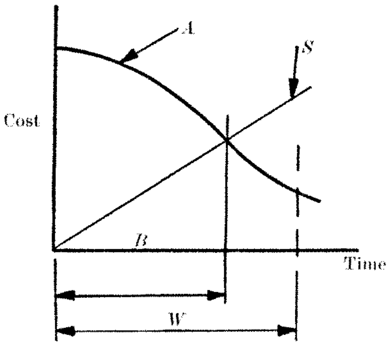

Fig. 1. Economic factors in split-energy pumping. *A*, Addition cost of oscillatory equipment (initial cost + maintenance + depreciation). *S*, Saving in energy cost. *B*, Break-even time. *W*, Oscillatory equipment write-off time.

are foreshadowed. The experimental analytical equipment is also available[3,4].

BIOLOGICAL SCIENCES

Excretion of Murine Leukaemia Virus

THE study of mice experimentally infected with murine leukaemia virus (MuLV) has revealed leukaemogenic activity in the milk, saliva, urine and faeces, and typical MuLV particles in the mammary glands, salivary glands, and pancreas. MuLV has not been demonstrated, however, in the excretions or secretions of naturally infected mice[1-3]. The development by Hartley *et al.*[4,5] of the complement fixation test for murine leukaemia virus provided a sensitive *in vitro* assay for MuLV and a practical means for the detection of virus in tissues, mouth swabs and excretions. We report here studies on the isolation of virus from excretions and secretions of naturally infected high leukaemia strains AKR/J, C58/J and SJL/J.

The virus isolation studies were conducted on 6 to 10 month old retired breeders from the production colonies of the Jackson Laboratory. They were housed, twenty-five to a cage, in stainless steel cages (12 × 24 × 6·5 inch), provided with white pine shavings and hardwood chips for bedding. The cages were cleaned weekly; food and water were provided *ad libitum*. Mouth swabs were obtained by rolling cotton swabs in the mouth until they became moistened. Urine and faeces were collected on fresh strips of aluminium foil, and blood samples were obtained from cuts in the tail made with razor blades disinfected with alcohol. Specimens were taken at 14-day intervals from four to eleven mice of each strain, approximately half from males and half from females. They were placed in vials containing 1 ml. of Eagle's minimum essential medium with 200 units of penicillin and 200 μg of streptomycin per ml., and stored at −70° C until they could be tested. All specimens were tested individually.

The complement fixation assay for MuLV involves inoculation of secondary mouse embryo cell cultures from NIH Swiss mice and Fischer rat embryo cell cultures as already described[4-6]. After incubation for 21 days the cells were scraped off the plates, suspended in approximately 0·6 ml. of the culture fluids and sonicated gently. The resulting cell packs were assayed for the group specific MuLV antigen by the complement fixation test against anti-Moloney sarcoma virus rat sera.

The results are presented in Table 1: MuLV was detected in four of forty-four AKR/J faecal specimens; six of the forty-four AKR/J blood specimens were positive, indicating that they were viraemic. The positive sample of rat embryo cell culture differed from those on mouse embryo cell culture. We isolated MuLV from three of thirty-six C58/J blood specimens, but did not detect virus in any of twenty-four SJL/J samples, although Hartley consistently isolated virus from SJL/J spleen extracts[5]. Thus naturally infected AKR/J mice do excrete leukaemia virus in the faeces and MuLV can be recovered without further concentration techniques such as ultracentrifugation and ultrafiltration[7].

Table 1. MURINE LEUKAEMIA VIRUS ISOLATED FROM BLOOD, SALIVA AND EXCRETIONS

* Mouse embryo tissue culture.
† Rat embryo tissue culture.
‡ No. isolations/No. mice sampled.

Our findings seem relevant to the question of the horizontal transmission of MuLV, and are consistent with those of Aoki *et al.*, who observed the development of soluble Gross virus antigen (GSA) in GSA negative C3Hf/Bi mice, and the appearance of GSA antibody in GSA negative C57Bl/6 mice after these were placed in cages with GSA positive AKR mice[8].

According to available evidence, the transmission of MuLV occurs chiefly vertically as a covert viral genome[9]. By contrast, horizontal spread is both infrequent and unimportant (ref. 9 and unpublished observations of R. J. H., W. T. Lane, H. M. and D. D. M.). Most, if not all, inbred mice carry vertically transmitted, that is, inherited, RNA tumour virus information (refs. 9, 10 and unpublished observations of R. J. H., W. T. Lane, H. M. and D. D. M.). The degree of "virus expression" depends largely on host genetic factors[9,11]. Complete, infectious forms of MuLV have been found in only few inbred strains, and in most the virus is covert or repressed to varying degrees (ref. 9 and unpublished observations of H. M., D. D. M. and R. J. H.). AKR/J and C58/J mice are two strains with full expression of virus characterized by the presence in tissues of complete, infectious MuLV. Our experiments demonstrate by direct isolation the presence of complete virus in excretions and secretions. Because the viral envelope on completion at the cell surface acquires host cell-specific components, including major histocompatibility (*H2*) antigens, strains of mice differing in *H2* genotype are resistant to horizontal transmission of excreted MuLV (refs. 12-16 and unpublished observations of H. M., D. D. M. and R. J. H.). We therefore interpret the findings of Aoki *et al.*[8] as evidence for an accelerated rate of indigenous virus expression influenced by the stress of exposing mice of two different strains to one another, rather than as proof for horizontal virus spread. Certain strains of mice develop viral envelope (neutralizing) antibodies spontaneously. Even in the case of Law[2], who reported that the urine and faeces of mice infected with the Moloney leukaemia virus remained leukaemogenic (by *in vivo* assay) after 3 h exposure to room temperature, the actual transmission of virus cannot be distinguished from activation of endogenous MuLV. Thus, the fact that certain "high leukaemia" strains with full expression of viral function excrete "infectious" virus has little significance as a mode of viral spread. Rather, it may represent a defence mechanism of the host for shedding unintegrated cellular contaminants.

Inhibition of Glycoprotein Synthesis in L5178Y Mouse Leukaemic Cells by L-Asparaginase *in vitro*

L-Asparaginase (EC 3.5.1.1), which hydrolyses the amide group of asparagine, inhibits certain neoplasms[1-4] and is used for treating human acute leukaemias[5,6]. Although asparaginase sequentially inhibits protein, RNA and DNA synthesis[7], its cellular action is undefined. We have investigated the effects of asparaginase on the synthesis of carbohydrate–amino-acid linkages in glycoproteins which involve the amide group of asparagine and N-acetyl-glucosamine residues[8]. Our preparation of L-asparaginase (from *Escherichia coli*, 321–363 U/mg protein) was free of contaminating enzymatic activity, although it was slightly active (2·1 per cent of the activity towards asparagine) with glutamine as substrate. The preparation was free of glycosidase and proteolytic activities[9,10].

L5178Y cells (mouse leukaemia cell line) were grown in exponential phase in sealed containers in Fischer's medium[11]. Protein was determined by the method of Lowry *et al.*[12]. L5178YF cells grown in identical conditions were carried in CDF$_1$ mice before transfer to culture. Fetuin[13] and porcine submaxillary gland glycoprotein[14,15] were prepared and determined as previously described[16].

The data in Fig. 1 show that glycoprotein and protein synthesis in L5178YF cells were inhibited by L-asparaginase. Inhibition of glycoprotein synthesis (66 per cent in 20 min) was more marked than inhibition of protein synthesis (30 per cent in 20 min).

Table 1. TRANSFER OF N-ACETYLGLUCOSAMINE FROM UDP-N-ACETYLGLUCOSAMINE INTO ENDOGENOUS AND EXOGENOUS ACCEPTORS IN L5178Y CELLS AND ASPARAGINASE-TREATED L5178Y CELLS

	C.p.m./mg protein	
	Endogenous	Exogenous
L5178Y	4,344 ± 21	6,139 ± 29
L5178Y + asparaginase	2,591 ± 16	6,241 ± 73

Two groups of 10^6 L5178Y cells in 10 ml. of Fischer's medium were incubated for 1 h at 37° C, one with 1,000 units of L-asparaginase (L5178Y + asparaginase) and one with 0·1 M Tris buffer (*p*H 7·6). After the incubation the cells were centrifuged at 5,000*g* and the pellet homogenized in 0·1 per cent 'Triton X-100' in a Ten Broeck homogenizer. This extract was then used for assay of transfer of N-acetylglucosamine into endogenous and exogenous acceptors. The assay for endogenous activity contained: 100 μl. of the 0·1 per cent 'Triton X-100' extract, 10 μl. of 0·1 M $MnCl_2$, 50 μl. of glass distilled water, and 10 μl. of the UDP-N-acetyl-[^{14}C]glucosamine (25 nCi, approx. 6×10^{-11} mole) to a final volume of 0·170 ml. Incubation was 37° C for 1 h, after which radioactivity was determined by methods previously described[17]. The assay system for exogenous activity contained the above plus 50 μl. of the fetuin acceptor in place of the water. The acceptor for the exogenous assay was made by removing sialic acid, galactose and N-acetylglucosamine from fetuin[18]. Means ± 1 *S.D.*

Asparaginase-treated cells did not synthesize appreciable amounts of protein or glycoprotein after 20 min (Fig. 1). Hydrolysis and chromatography of the radioactive products[17] indicated 100 per cent recovery of the respective leucine and fucose fractions. Similar experiments on L5178Y cells (Fig. 2) indicate that incorporation of aspartic acid into protein was inhibited later, and to a lesser extent than was glycoprotein synthesis.

High levels of asparaginase did not completely inhibit protein or glycoprotein synthesis; a residual, asparaginase-resistant synthesis was observed. Presumably this involved synthesis of proteins devoid of L-asparagine and glycoproteins not containing the asparagine–N-acetylglucosamine linkage. Preincubation with L-asparaginase (Fig. 2) for 1 h before measurement of glycoprotein synthesis gave results no different from those obtained when enzyme was given simultaneously with the labelled precursors. This indicates that the enzyme affected nascent synthesis and not existing glycoprotein precursor pools. In these experiments, leucine and fucose were recovered 100 per cent; glucosamine was recovered 70 per cent as glucosamine, 20 per cent as galactosamine, and 10 per cent as N-acetylneuraminic acid.

The transfer of N-acetylglucosamine to endogenous acceptors was impaired by incubation of L5178Y cells

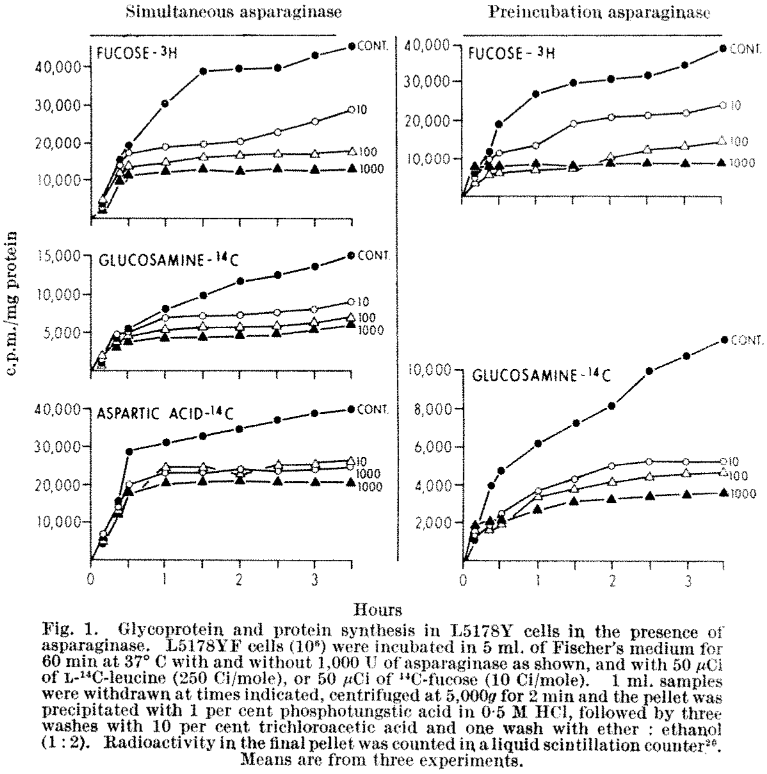

Fig. 1. Glycoprotein and protein synthesis in L5178Y cells in the presence of asparaginase. L5178YF cells (10^6) were incubated in 5 ml. of Fischer's medium for 60 min at 37° C with and without 1,000 U of asparaginase as shown, and with 50 μCi of L-^{14}C-leucine (250 Ci/mole), or 50 μCi of ^{14}C-fucose (10 Ci/mole). 1 ml. samples were withdrawn at times indicated, centrifuged at 5,000*g* for 2 min and the pellet was precipitated with 1 per cent phosphotungstic acid in 0·5 M HCl, followed by three washes with 10 per cent trichloroacetic acid and one wash with ether : ethanol (1 : 2). Radioactivity in the final pellet was counted in a liquid scintillation counter[26]. Means are from three experiments.

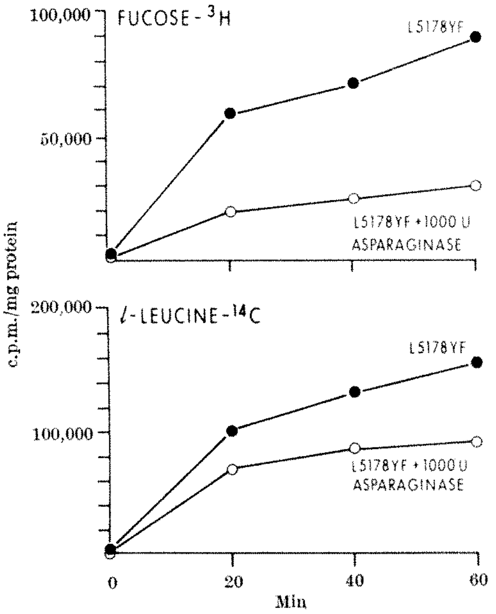

Fig. 2. Glycoprotein and protein synthesis in L5178Y cells in the presence of asparaginase. L5178Y cells (3×10^6) were incubated in 10 ml. of Fischer's medium with the indicated units of asparaginase, and either 50 μCi of ^{3}H-fucose (10 Ci/mole), 10 μCi of ^{14}C-aspartic acid (100 Ci/mole) or 10 μCi of ^{14}C-glucosamine (50 Ci/mole). For experiment 1, isotopically labelled compound and L-asparaginase were added together; for experiment 2, cells and L-asparaginase were incubated for 1 h before addition of the isotopically labelled compound. Protein bound radioactivity was determined as given in Fig. 1. Experiment 1 (top) and experiment 2 (bottom).

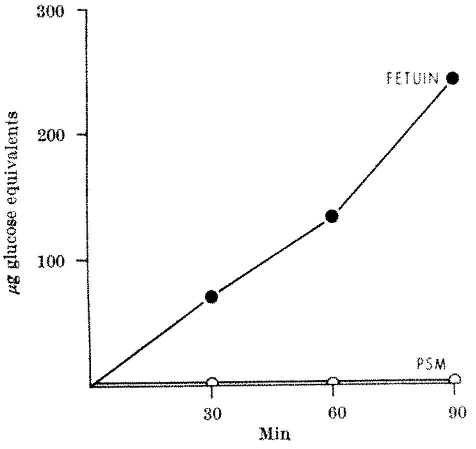

Fig. 3. Release of carbohydrate from fetuin by asparaginase. Fifty mg of fetuin or porcine submaxillary gland glycoprotein (PSM) was incubated at 37° C with 1,000 U of asparaginase in 1 ml. of 0·1 M Tris (pH 7·6). At indicated times 0·25 ml. of the reaction mixture was removed and 0·75 ml. of 10 per cent trichloroacetic acid was added. This mixture was centrifuged at 32,000g for 10 min and the supernatant analysed (anthrone test). Data are given as μg glucose equivalents in 7·5 per cent trichloroacetic acid. Means are from three experiments. Controls, which gave no release of glucose equivalents, included fetuin alone, porcine submaxillary gland glycoprotein incubated alone, asparaginase incubated alone, or either substrate incubated with 1,000 U of L-asparaginase previously incubated at 100° C for 1 h.

with L-asparaginase (Table 1). The inhibition was 40 per cent; thus 60 per cent of the acceptors were available—presumably those not directly requiring the amide nitrogen of asparagine. When exogenous acceptors were added to the reaction, both enzyme-treated and control preparations had identical activity, so that the acceptors and not the transferase enzymes were impaired by L-asparaginase. Hydrolysis of the radioactive product indicated recovery of 100 per cent as unchanged N-acetyl-[^{14}C]glucosamine.

L-Asparaginase released carbohydrate from fetuin but not from porcine submaxillary gland glycoprotein (Fig. 3). This action of L-asparaginase could cause cleavage of formed glycoproteins in cell membranes.

Because residual glutaminase activity is present in the asparaginase preparation, and high levels of asparaginase were used in the experiments, the results could be explained in part by depletion of glutamine residues as opposed to asparagine residues. It is clear, nevertheless, that L-asparaginase has the ability to cleave formed glycoproteins and to inhibit glycoprotein synthesis as well as extensively inhibiting protein synthesis. Because membrane glycoproteins turn over rapidly[19], either action could cause membrane lysis and cell death. The activity of L-asparaginase towards certain tumour cells may be caused, in part, not only by absence of L-asparagine synthetase but also may be related to the increased glycoprotein transferase activity—and therefore glycoprotein turnover—found in cells which have undergone oncogenic transformation[20]. The results are of interest in the light of those recently described[21] in which L-asparaginase was found to suppress the immune system, for immunoglobulins are glycoproteins; moreover, glycoproteins may be necessary for the rapid proliferation of lymphoid cells.

Synthesis of Herpes Simplex Virus Structural Proteins in Arginine Deprived Cells

Arginine deprivation of herpes simplex virus infected cells resulted in (*a*) inhibition of the synthesis of infectious virions[1-5]; (*b*) a decline in the rate of cellular protein synthesis[3]; (*c*) a continuous replication of viral DNA[3]; (*d*) synthesis of virus specific proteins[6]; and (*e*) synthesis of

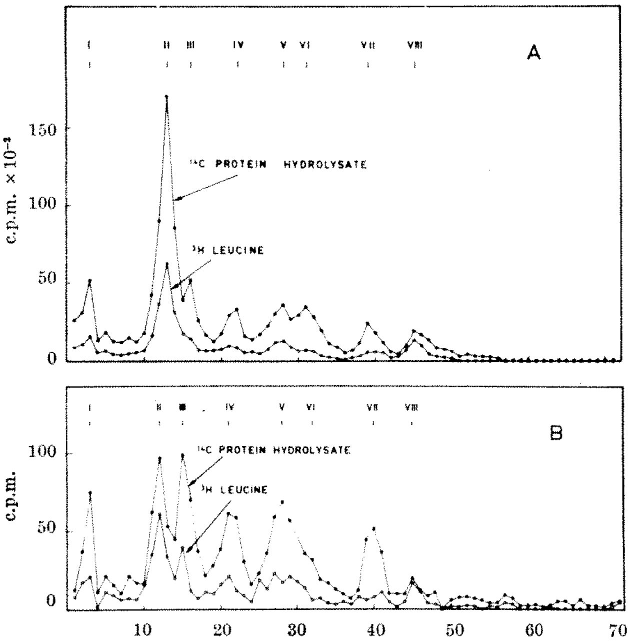

Fig. 1. Electrophoretograms of proteins in nuclear (*A*) and cytoplasmic (*B*) herpes simplex virions, synthesized in the absence and presence of arginine in the culture medium. BSC$_1$ cells were infected with 10 p.f.u./cell of the HF strain of herpes simplex virus. After an adsorption period of 3 h at 37° C, the cells were washed and incubated for 15 h in Eagle's medium without arginine but containing 1/40 the amount of leucine and 10 μCi of ^{3}H-leucine. At the end of this period, the infected cell cultures were washed with buffer and reincubated for 5 h in medium containing excess leucine (10 times the regular concentration), arginine (twice the regular concentration) and 1/40 the concentration of all the other essential amino-acids. The cultures were labelled with 10 μCi of ^{14}C-algal protein hydrolysate. At the end of the incubation period the cells were scraped off the glass and disrupted in a Dounce glass homogenizer. The nuclear and cytoplasmic fractions were obtained and the enveloped virions were prepared by centrifugation in sucrose gradients. The virus bands were removed from the sucrose gradients, the virions were sedimented at 100,000*g* for 60 min and dissolved in urea, sodium dodecyl sulphate and 2-mercaptoethanol and analysed by electrophoresis in acrylamide gels.

virus specific antigens (ref. 7 and personal communication of A. B. Sabin). Addition of arginine to the deprived cells resulted in the restoration of virus replication and the envelopment of the viral DNA[3]. Recently, the analyses of enveloped herpes virions[8,9] by acrylamide gel electrophoresis[10] demonstrated that the herpes virion is composed of seven major structural viral proteins (designated II to VIII[10]). Two of these proteins (designated II and VIII) constitute the viral capsid; two proteins constitute the viral core proteins (VII and VI); and three glycoproteins (designated III, IV, V) are present in the viral envelopes. Protein III is found in the large outer envelope of the cytoplasmic herpes simplex virions[10]. Protein I seems to be an aggregate of one of the envelope proteins and protein IX constitutes only 1 per cent of the structural proteins[10]. It was therefore possible to identify the virus specific structural proteins synthesized in the infected cells in the absence of arginine and used for virion formation on the addition of arginine.

We have incubated herpes virus infected cells in the absence of arginine and the proteins synthesized were labelled with ^{3}H-leucine. In order to determine if functional viral structural proteins were synthesized in the arginine deprived cells, the radioactive leucine was "chased" with excess leucine, virus synthesis was triggered by adding excess arginine and the newly synthesized viral proteins were labelled with ^{14}C-amino-acids. The analysis of the mature herpes virions demonstrated that the two capsid proteins (designated II and VIII) and the envelope proteins were found to be synthesized in the arginine deprived cells and utilized for the formation of virus progeny when arginine became available.

In order to characterize the structural proteins synthesized in the infected cells in the absence of arginine, BSC$_1$ cells were infected with the HF strain of herpes simplex virus (multiplicity of infection 10 p.f.u./cell). After the initial 3 h of virus adsorption[11], the cells were incubated for 15 h at 37° C in arginine free Eagle's medium[12] containing 1/40 of the regular leucine concentration, as well as 10 μCi per culture of ^{3}H-leucine (specific activity 380 mCi/mmole). At the end of the incubation period, the cultures were washed with buffer and were reincubated at 37° C in Eagle's medium containing excess leucine (ten times) and arginine (twice the regular concentration), as well as 1/40 of the other essential amino-acids. In these conditions further incorporation of radioactive leucine was prevented and the synthesis of virus progeny was resumed. The cells were then labelled with 10 μCi/culture of ^{14}C-algal protein hydrolysate (specific activity 54 mCi/m atom carbon) for a period of 5 h at 37° C. Isotopes were obtained from the Radiochemical Centre, Amersham. The cells were harvested and disrupted in a glass Dounce homogenizer. The nuclear and the cytoplasmic fractions were obtained by centrifugation and the enveloped virions were isolated by zone centrifugation in 12–52 per cent sucrose gradients[8,9]. The bands of enveloped nuclear and cytoplasmic virions were removed from the sucrose gradients and analysed by electrophoresis in acrylamide gels[10,13]. The structural proteins which were synthesized in the infected cells during the period of arginine deprivation were labelled with ^{3}H-leucine. Viral proteins synthesized in the infected cells after the addition of arginine were labelled with ^{14}C-amino-acids.

Previous studies[3] had demonstrated that in the absence of arginine from the culture medium, the synthesis of herpes virions was inhibited, but the addition of arginine to the culture medium resulted in a prompt resumption of virion formation. In the present experiments it was found that the addition of arginine to the deprived cultures resulted in the synthesis of a virus progeny and the herpes virions were recovered from the nuclear and the cytoplasmic fractions of the infected cells. The electrophoretograms of the nuclear virions (Fig. 1*A*) demonstrated the presence of the seven major proteins (II to VIII), all of them labelled with ^{14}C-amino-acids. Two of the proteins (II and VIII), however, also contained protein molecules which were labelled with ^{3}H-leucine. Protein V also contained a small amount of ^{3}H-leucine labelled molecules (Fig. 1*A*). This result suggested that polypeptide chains of proteins II, VIII and possibly also V were synthesized in the arginine deprived herpes virus infected cells, at a time when the formation of herpes virions was completely prevented. These peptides were transported to the nuclei and were utilized for the formation of the virus particles after arginine was added to the cultures. In contrast, the virus progeny contained viral core proteins (VII and VI) as well as the glycoproteins (III, IV and V) which were synthesized after the addition of arginine to the deprived cells. Nevertheless, to determine if protein III (the glycoprotein present in the large viral envelope) was synthesized in the absence of arginine, analyses were also made on herpes simplex virions present in the cytoplasm. We have found (our unpublished results) that the cytoplasmic herpes virions contain more of protein III than the nuclear virions. The results in Fig. 1*B* demonstrate that in addition to tritium labelled proteins II, VIII and V, tritium labelled proteins III and IV were also present in small amounts in the virions, indicating their synthesis in the arginine deprived cells, and were used for the envelopment of the virus particles after the restoration of arginine.

The ability of the arginine deprived herpes virus infected cells to synthesize the viral capsid proteins II and VIII and possibly also the envelope protein V might reflect the amino-acid composition of the proteins. We have found[10] that proteins II, VIII and V have the lowest arginine/leucine ratio among the herpes virus structural proteins (0·74, 0·66 and 0·89, respectively).

This does not explain, however, the synthesis of proteins III and IV which have a higher arginine/leucine ratio. This finding of continued synthesis of proteins II, VIII, IV and V in the herpes virus infected cells, in the absence of an exogenous arginine source, indicates that arginine is available for protein synthesis in the deprived cells, but most probably in restricted amounts. Our finding that capsid and envelope proteins are synthesized in the arginine deprived cells might explain the reports (ref. 7 and personal communication of A. B. Sabin) that herpes viral antigens were synthesized and present in the cytoplasm of herpes virus infected, arginine deprived cells[7]. This might resemble the continued synthesis of adenovirus antigens in arginine deprived adenovirus infected cells[14].

The results might also explain the reason for the lack of herpes virion synthesis in the arginine deprived cells. In these conditions, the synthesis of the virus core proteins (designated VII and VI) or their use and the formation of viral capsids were prevented. It is therefore assumed that in the arginine deprived cells, the packing of the viral DNA was prevented, although the replication of viral DNA was not affected[3]. Thus in the absence of arginine in the medium, the proteins essential for the initial encapsidation of the herpes virus DNA genomes are not available. The synthesis of capsid and envelope proteins will continue in the arginine deprived cells although the formation of virus progeny is inhibited.

Two Dimensional Cell Separation: Comparison of Embryonic and Adult Haemopoietic Stem Cells

EMBRYONIC and adult haemopoietic stem cells have been shown to differ in such properties as proliferative capacity[1,2], sensitivity to gamma irradiation[3], suicidal levels of tritiated thymidine[4] and seeding efficiency to the spleen[5] as well as susceptibility to suppression of erythroid differentiation in polycythaemic recipients[6].

Moore *et al.*, using the technique of equilibrium density gradient centrifugation, have determined the density distribution profiles of haemopoietic stem cells at various stages of mouse foetal liver development and in adult marrow[7].

The results of this study are summarized in part in Fig. 1, which shows the density distribution profiles of the earliest detectable foetal liver stem cell population (10·5 days gestation) contrasted with that of adult bone marrow. A homogeneous density population of 10·5 day foetal liver stem cells, restricted to the light density region of the gradient, was observed, contrasting with the heterogeneous adult marrow profile located chiefly in the denser regions of the gradient. The density profiles determined at stages of liver development between 10·5 days gestation and birth revealed a progressive shift to the more dense region of the gradient with the appearance of stem cells possessing similar density and spleen seeding efficiency to those of adult marrow.

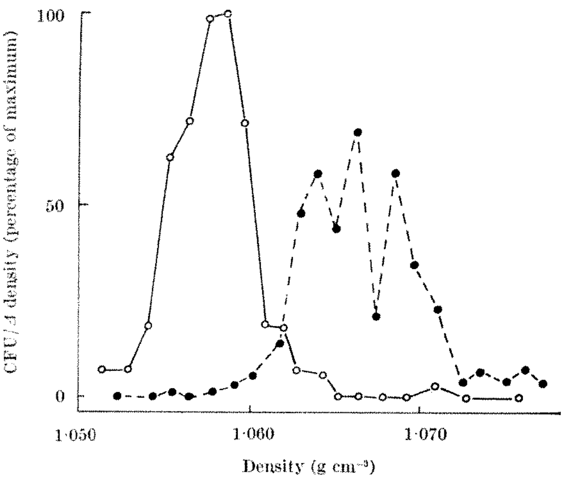

Fig. 1. Density distribution profiles of *in vivo* CFU present in 10·5 day embryonic liver (○—○) and 8 week old adult bone marrow (● - - - ●) from C57Bl–CBA donors. Recipients were given 750 r. X-irradiation. Results were comparable with the C57Bl6 donors used in the present study. The area under the profiles has been normalized for comparison.

Our experiments indicated that only a small proportion $(<2$ per cent) of adult marrow stem cells were of the same density as those of 10·5 day foetal liver. The difference in spleen seeding efficiency of the foetal liver stem cells (4·9 per cent) and stem cells of the same density in adult marrow (12 per cent), however, suggested that density similarity did not imply functional similarity[7,18].

Our purpose here is to describe the application of a further parameter, that of cell size, to characterize more fully stem cells of similar density in early foetal liver and adult marrow. Miller and Phillips[8] have introduced a modified version of the Peterson and Evans method[9] for separation of cells on the basis of differences in cell sedimentation velocity. This sedimentation rate depends largely upon the volume of the cell but also shows a dependence on the density of the cell (unpublished work of J. S. H.) Equilibrium density gradient centrifugation separates cells solely on the basis of density, which is a function of many cell parameters including size[10]. In order, therefore, to obtain the highest degree of resolution among a complex mixture of cells varying in size and density, a separation method using the two techniques in series would be expected to yield much better results than either technique alone.

Stem cells were determined by the *in vivo* CFU assay of Till and McCulloch[11]. The preparation of foetal liver and marrow cells from (CBA × C57)F$_1$ and C57Bl6 mice has been described previously[7]. Because of the density homogeneity (1·0565–1·0585 g cm^{-3}) of 10·5 day foetal liver stem cells, they were not subjected to preliminary fractionation by density. Marrow cells, obtained by flushing femoral shafts of 8 week old mice, were subjected to density gradient separation using the technique of Shortman[10]. In brief, marrow (five donors) or liver cells (twenty-five donors, 200 CFU) were dispersed in a linear gradient of bovine plasma albumin (14–28 per cent by weight) and cells were brought to the position of their buoyant density by centrifugation for 45 min at 4° C. Density fractions were collected by upward displacement of the gradient and, after density determination of each fraction, cells in the density range 1·0565–1·0585 (680 CFU) were pooled and then subjected to a velocity sedimentation separation using the technique of Miller and Phillips[8]. Sedimentation was carried out at 4° C in gradients of

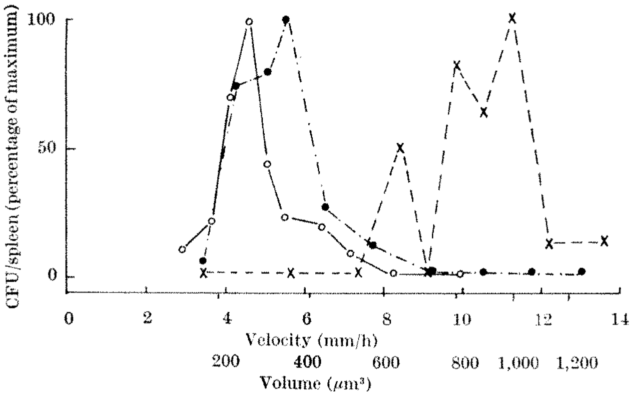

Fig. 2. Sedimentation velocity profiles of *in vivo* CFU present in 10·5 day embryonic liver (× - - - ×), adult bone marrow (ρ1·0565–1·0585) (○—○) and spleen (●—·—●) from lethally irradiated recipients given 2×10^5 adult bone marrow cells 7 days before death. Cell loading in all experiments was less than 3×10^6 cells per ml. (10 ml. sample) for bone marrow or spleen and 2×10^6 cells per ml. for embryonic liver. Cell volumes were determined on the pulse height analyser.

4–30 per cent foetal calf serum in Tris buffered Eagle's MEM (Difco) for 2·5 h in the case of embryonic cells or 4 h in the case of the bone marrow cells. Recovery of CFU activity was 80–100 per cent.

The sedimentation profiles of 10·5 day foetal liver stem cells and of the equivalent density region of adult marrow stem cells are shown in Fig. 2. The results show that the foetal liver stem cells sediment more rapidly than those of equivalent density in adult marrow. Because the foetal and adult stem cells have been selected to possess similar density, the sedimentation velocity results can be directly interpreted in terms of the volume of each cell (unpublished work of J. S. H.). In both of these experiments enrichment of CFU was about ten-fold.

Using a pulse height analyser equipped with a Coulter counter aperture[8], data for the relationship of volume and density with sedimentation velocity were obtained using a range of densities of normal spleen cells (unpublished work of J. S. H.). These data have been used to plot the volumes indicated in Fig. 2. The adult marrow stem cells in density region 1·0565–1·0585 showed a major population of volume 260 μm^3 and a minor population of 430 μm^3 (equivalent to spherical diameters of 7·9 and 9·3 μm). In contrast the foetal stem cells of similar density revealed major populations of volumes 820 and 1,000 μm^3 (equivalent to spherical diameters of 11·6 and 12·4 μm). It is difficult to relate these spherical diameters to values measured on smearing; but mouse myeloma cells of spherical diameter 13 μm have a diameter of 16·5 μm on smearing, so it seems possible that the largest embryonic stem cell would be 15–16 μm on a smear.

Our results indicate that stem cells of early embryonic type are absent from adult resting marrow. It is therefore unlikely that any morphological similarity would be evident. In this context M. A. S. M. and Owen[12,13], using autoradiographic and histological techniques in conjunction with chromosome marker studies, have tentatively described the stem cell in early embryonic haemopoiesis as a large (> 15 μm diameter) blast-type cell characterized by a prominent nucleolus and extensive cytoplasmic basophilia. In contrast, in adult marrow, smaller cells of the small and medium lymphocyte[14], transitional cell[15] or monocytoid[16] types have been implicated as haemopoietic stem cells.

Niewisch *et al.* carried out density separation of adult regenerating spleen and suggested that a minor population of stem cells from exceptionally high density region of the gradient (1·020) were large cells of 14–17 μm diameter in smears and with intensity basophilic cytoplasm[17]. It therefore seemed possible that differences in size and morphology between embryonic and adult marrow stem cells may be the result chiefly of differences in proliferative activity of the stem cell population rather than of a maturation sequence involving irreversible changes in stem cell morphology. In order to test this hypothesis, bone marrow cells (2×10^5 per recipient) were passaged in lethally irradiated recipients for 7 days. A fraction of the spleens of these animals (1,200 CFU) was then submitted to a sedimentation velocity separation for CFU. The results indicated in Fig. 2 are clearly in accord with the notion that adult bone marrow is incapable of reverting to the early type embryonic stem cells, even in conditions of extreme proliferation. It therefore seems that embryonic stem cells undergo a process of differentiation with age which is reflected in volume and density changes.

Viability of Isolated Nuclei

Amoeba proteus has been used with some success in studies of nuclear and cytoplasmic activities where transfer of the nuclei from one cell to another, or comparative studies of anucleate and nucleate cells, allow separation of the activities[1,2]. This technique, however, answers many questions only partially, for it has been impossible to observe the behaviour of nuclei in the absence of cytoplasm. We report here an initial investigation to obtain a medium in which nuclei can be isolated for short periods without damage.

The ultimate criterion for damage is whether such nuclei can assume their normal functions on return to anucleate cytoplasm; functions, that is, which lead to growth and division of the cell. We decided to use 35 mM KCl as an isolating medium because this is the concentration of K^+, the main intracellular cation[3,4], a fact that previous studies had overlooked[5,6]. Though nuclei could survive in 35 mM NaCl or in the more complex mixtures known to preserve synthetic ability, such as those of Honda[7] and Rusch[8], in our hands KCl has given the most promising results. Isolation of nuclei in 35 mM KCl for periods of up to 15 min gave a survival for nuclei only

Table 1. SURVIVAL OF AMOEBAE CONTAINING NUCLEI ISOLATED IN 35 mM KCl FOR VARYING TIMES

	Controls		Nuclei returned to anucleate cytoplasm after isolation					
	Direct transfer of nuclei from one amoeba to another	Double transfer (retransfer of nuclei 0·25–1 h after the first transfer)	In Chalkley's medium for 5 minutes	In KCl medium for 5–10 minutes	10–15	15–25	40–60	In KCl medium for 7–15 min using the pipette isolating method
No. of transfers	50	30	20	222				65
Percentage viable*	90	70	0	65	60	35	10	25
Average time (days) of first division after transfer	2	3·5	—	7	9	9	14	10

* Operated amoebae were kept in small dishes until they either died or formed a clone of 20–30 cells; they were then moved to vials with wheat grains and kept until they formed clones of several hundred amoebae. This allowed for delayed lethality or for late development of any abnormalities.

slightly lower than that obtained for control double nuclear transfers, that is, 60–65 per cent (Table 1).

The behaviour of an anucleate amoeba given a nucleus which has been isolated separates into three phases.

(1) Reactivation. Amoebae were able to attach to the substratum and move about after 90 per cent of the nuclear operations, provided that the operations themselves had been successful, that is, if the nucleus had been pushed clear of the cytoplasmic membrane and the tear in the membrane repaired. Attachment occurred within 15 to 30 min of the operation, but unless it was followed by acceptance of the nucleus the ability to attach and move disappeared after one to several days and amoebae then behaved as if they contained no nucleus. Some factors influenced the speed of reactivation; for example, young isolated nuclei were good reactivators, anucleate cytoplasm given 1–2 h old nuclei attaching sooner than cytoplasm with nuclei of other ages; nuclei approaching division were poor reactivators, some 8–12 h frequently passing before amoebae became attached and moved; nuclei isolated for periods of 20 min or more reactivated, but took several hours to do so. About 30 per cent of reactivated amoebae did not assume any activities other than attachment and movement.

(2) Acceptance. When attachment and movement continued for several days and were accompanied by feeding, growth and continued survival, it was assumed that the nucleus had been accepted by the cell. About 10 per cent of these nuclei were able to assume only a limited number of nuclear activities. Such cells died without dividing 3–6 weeks after the transfer operation.

(3) Division. The ability of operated amoebae to form viable clones of apparently normal amoebae was taken as proof that such nuclei received no irreversible damage during their period of isolation. Sixty per cent of reactivated amoebae were capable of division. Almost all such amoebae continued to divide and formed apparently normal clones.

Many factors, such as the age of the nucleus at the time of isolation, contributed to the success of isolated nuclear operations. Nuclei isolated when less than 3 h old stuck to the glass operating needle, were very difficult to see or to move and, even when successfully transferred and accepted by anucleate cytoplasm, were usually unable to divide. Nuclei approaching division at the time of isolation frequently underwent abnormal divisions. The percentage of nuclei accepted by anucleate cytoplasm was greatly influenced by the operation procedure. The most successful method of isolation involved the use of the oil chamber nuclear transfer method developed by de Fonbrune with donor amoebae in drops of KCl, recipient enucleated amoebae in small drops of Chalkley's medium and a second larger drop of Chalkley's medium placed nearby into which operated amoebae could be drawn immediately the operation was over. Large differences in survival occurred if, for example, recipient cytoplasm was left for any length of time in the KCl medium; if more than one amoeba was allowed to cytolyse in the drop containing isolated nuclei; or if more than a very small amount of Chalkley's medium was allowed to accompany the recipient cytoplasm into the drop of KCl with isolated nuclei.

Nuclei used for *in vitro* studies have to be moved from one drop to another. To simulate these conditions nuclei were isolated in KCl in small dishes under a dissecting microscope by sucking amoebae into and out of a narrow pipette. Nuclei could be picked up as they floated free of bursting amoebae, and washed in fresh KCl. The final stage of the operation was completed with the de Fonbrune manipulator after placing the nuclei in drops of KCl in oil chambers. Exposures of 7–15 min using nuclei isolated in this way have so far given a much lower survival than was obtained when nuclei were handled only during the moments of isolation and retransfer. Attempts are being made to improve this technique, both for use in treating isolated nuclei with chemicals and for following the activities of isolated nuclei using labelled nucleic acid and protein precursors, followed by reintroduction into anucleate cells.

Previous experiments on *Amoeba proteus* have shown that nuclei are seldom able to survive more than 1 min isolation in a variety of saline and sugar media[5,6]. Our experiments show that nuclei can survive much longer periods of isolation without permanent damage if a 35 mM KCl medium is used. Immediate changes to the nucleus, however, such as shrinkage and loss of turgidity, take place while nuclei are in KCl. Such changes are evident for several days after retransfer, the shrivelled nuclei swelling in the recipient cytoplasm but remaining soft and transparent. Use of tritium-labelled uridine showed that no measurable amount of DNA transcription took place at this stage, and several days to more than a week elapsed before growth and division of the amoebae occurred (Table 1).

Isolation of Anti-polysaccharide Antibodies with Glutaraldehyde Cross-linked Lipopolysaccharides

IMMUNOADSORBANTS are used chiefly for the isolation of antibodies against protein antigens. Glutaraldehyde has already been successfully used as a cross-linking agent to convert carboxypeptidase A[1], trypsin[2] and protein antigens[3] into insoluble derivatives retaining their specific biological properties. Few attempts have been made to

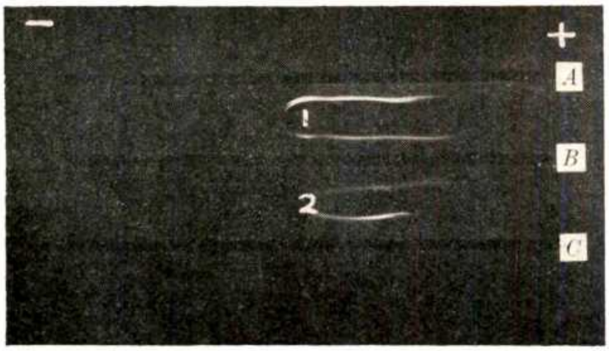

Fig. 1. Immunoelectrophoresis of lipopolysaccharide developed against antilipopolysaccharide antibody eluate and whole anti-live-culture serum against *E. coli* serotype 792. Wells (1 and 2): Lipopolysaccharide from *E. coli* serotype 792; troughs (*A* and *C*): anti-live-culture serum against *E. coli* serotype 792; *B*, antibody eluate.

prepare immunoadsorbents from substances other than proteins[4,5]. In so far as lipopolysaccharides have not been insolubilized, we have attempted their cross-linkage to develop a cross-linking procedure, using glutaraldehyde.

The lipopolysaccharide was obtained from a local strain of serotype 792 (classified by Edwards and Ewing[6] as *Escherichia coli* 028 K73 (B), Katwijk type) according to the method of Westphal *et al.*[7]. Glutaraldehyde (final concentration 2 per cent) was added to a 1 per cent solution of lipopolysaccharide in 0·1 M phosphate buffer, *p*H 7·0. The solution was gently stirred for 1 h at room temperature. An equal volume of saturated ammonium sulphate was added and stirring was continued for another 30 min. The resulting precipitate was collected by centrifugation, repeatedly washed with 0·1 M phosphate buffer (*p*H 7·0), suspended in phosphate-buffered saline and stored at 4° C.

A sample containing 14 mg (estimated dry weight) of the suspension was mixed with 1 ml. anti-live-culture serum against serotype 792. The suspension was shaken for 2 h at room temperature. Following adsorption, the serum had an agglutination titre of 1 : 80 whereas the value before adsorption was 1 : 1,600 as determined by the "doubling-dilution" technique; roughly estimated, this meant an adsorption of 95 per cent. The precipitate was washed with phosphate-buffered saline free of protein (until zero absorbance at 280 nm). The bound antibodies were eluted with 0·2 M glycine buffer (*p*H 2·2) in the cold. The antibody recovery amounted roughly to 10 per cent (agglutination titre of the eluate, 1 : 160). This is in agreement with the findings of Kochwa *et al.*[8]. Immunochemical analysis revealed the presence of antilipopolysaccharide antibodies in the eluates (Fig. 1). The immunoelectrophoretogram (Fig. 2) shows that they belong to the IgG class but contain small amounts of IgM and also traces of albumin.

The lipopolysaccharide condensate was stored in the cold after washing with phosphate-buffered saline. Its O-specific determinants do not seem to have been damaged by interaction with glutaraldehyde, for it combines specifically with homologous antibody and not with heterologous antibody against *E. coli* 025. The immunoadsorbant was used repeatedly (four times) without significant reduction in its antibody binding capacity.

The mechanism of lipopolysaccharide–glutaraldehyde aggregation is not understood. Further experiments to elucidate the nature of the reaction and to improve quantitative antibody recovery are in progress.

Two Fractions with Macrophage Migration Inhibitory Activity from Sensitized Lymphocyte Cultures

Landsteiner and Chase[1] established the cellular basis of delayed hypersensitivity when they showed that the passive transfer of the delayed-type reaction from sensitized guinea-pigs to normal animals could be achieved with peritoneal exudate but not with serum. This immunological response can be measured *in vitro*, for the migration of non-sensitized macrophages can be inhibited by a migration inhibitory factor (MIF) produced by sensitized lymphocytes cultured in the presence of specific antigens[2,3]. Intradermal injection of MIF into non-sensitized guinea-pigs produces reactions characterized by induration, erythema and mononuclear infiltration.

Lymphocytes were obtained from the axillary, popliteal and inguinal lymph nodes of Hartley guinea-pigs which had been sensitized with complete Freund's adjuvant. A single cell suspension was prepared and cultured for 24 h at 37° C in the presence of 50 μg/ml. of tuberculin purified protein derivative (PPD; Parke Davis) in Eagle's minimum essential medium (MEM) containing 50 units penicillin and 50 μg streptomycin per ml. The cell suspension was centrifuged and the cell-free supernatant freeze dried and stored at −20° C. Sensitized cells cultured without added PPD were used as controls: 50 μg/ml. PPD was added just before lyophilization. In a typical experiment, 60 ml. of cell-free supernatant was lyophilized and the residue reconstituted with distilled water applied to a column (2·5 × 120 cm) of 'Sephadex *G*-100' which was equilibrated and eluted with 0·02 M Tris–HCl–0·1 M NaCl buffer, *p*H 7·3. Absorbance was measured at 280 nm and the effluent was separated into five fractions each of which was concentrated to 3 ml. Foetal calf serum (15 per cent) was added to aliquots of each fraction which were then tested in cell migration chambers as previously described[3]. Only fractions II and V were found clearly to inhibit the migration of macrophages. The MIF activity in fraction V cannot be simply attributed to a non-specific cytotoxic substance, for there was no detectable cytotoxic effect on non-sensitized guinea-pig lymphocytes as evaluated by ^{51}Cr release; rabbit anti-guinea-pig lymphocyte serum used in the same assay effected significant ^{51}Cr release.

Polyacrylamide gel electrophoresis[4] provided good resolution which revealed differences in the electrophoretic patterns of the five 'Sephadex' fractions. It was not possible, however, to ascribe MIF activity to a single electrophoretic component. The actual amount of MIF is extremely small because fraction II, on electrophoresis, had its activity contained only within 15 μg protein distributed among several electrophoretic components. This amount represents about 3 per cent of the protein (530 μg) applied to the gel. In terms of the total protein applied to the 'Sephadex' column (2·5 mg), MIF present in fractions II and V was purified approximately 150-fold and 60-fold, respectively. These fractions have average molecular weights of 67,000 and 12,000 respectively, as estimated from their elution positions on a calibrated 'Sephadex *G*-100' column. Bennet and Bloom[5] have previously estimated that MIF has a molecular weight of 67,000 and is able to induce in normal guinea-pigs inflammatory reactions which resemble delayed type reactions. Our fraction II seems to be quite similar to the MIF described by these investigators: it also produced a significant skin reaction in non-sensitized guinea-pigs. By contrast, fraction V exhibited *in vitro* activity, but no detectable ability to induce inflammatory reactions. Fraction V is not simply attributable to PPD, for in control experiments no MIF activity was found in its elution position on 'Sephadex *G*-100'.

The lack of skin reactivity of fraction V (mol. wt. 12,000) could be ascribed to its relatively small molecular size which, in turn, could cause more rapid diffusion from the reaction site and thus make this fraction less effective in the induction of the inflammatory reaction. Our data provide some evidence that the MIF in fraction II may be a different molecular species from that found in fraction V. Consequently, MIF might be a relatively small molecule which is able to associate with carrier molecules of various sizes. This would provide a mechanism for MIF to remain in the reaction site long enough to stimulate the inflammatory reaction.

Macrophage Migration Inhibition Test using Guinea-pig Macrophages and Human Lymphocytes

The capillary macrophage migration inhibition test[1,2], one of the few available satisfactory methods for the *in vitro* study of delayed hypersensitivity, has largely remained an animal experimental technique, for a ready source of human macrophages has not been available. The usefulness of the method has thus been limited. Attempts by Lawrence and David[3] to use human blood cells were fraught with technical difficulties and therefore apparently abandoned. The subsequent isolation of migration inhibition factor[4,5] diverted attention to the study of its properties. For example, when the factor was obtained from sensitive human lymphocytes it could inhibit guinea-pig macrophages[6], but exploitation of this property did not increase significantly the study of human delayed hypersensitivity. The absence of sufficient macrophages (monocytes) in human peripheral blood for the test to be carried out successfully was overcome by culturing lymph node cells for 72 h and then performing the usual capillary migration test[7]. None of these modifications has had wide application because of numerous practical difficulties brought on by further complication of an already difficult technique. The case of peripheral blood cells[8] failed to stand up to critical testing[9]. We wish to make a preliminary report of a successful method for the capillary migration inhibition test using guinea-pig macrophages and human peripheral blood lymphocytes. Fuller details of the technique, in view of its possible wide application in the study of human disease, will be published later.

Macrophages and lymphocytes were prepared separately for each experiment. The cells were mixed and, where appropriate, antigens were added in varying strengths. Capillary tubes were filled and placed in the incubation chambers.

To obtain the macrophages four or five cross-bred guinea-pigs of the Hartley strain were injected with 25–30 ml. of sterile warm liquid paraffin. Five days later the macrophages were washed out of the peritoneal cavity aseptically with N Parker 199 and pooled. The peritoneal exudate cells were separated, spun and washed three times in N Parker 199. The second wash was preceded by osmotic lysis of red cells with 0·5 N Parker 199 for exactly 60 s and the osmolality was corrected by the addition of 1·5 N Parker 199. To obtain the lymphocytes 25 ml. of peripheral venous blood from human volunteers was defibrinated with glass beads and mixed with 3 per cent gelatine[10]. After 45–60 min the supernatant containing the white blood cells was collected, spun and washed three times with N Parker 199. The second wash was preceded by osmotic lysis of red blood cells as for the macrophages. The lymphocytes were then counted.

Twelve conical centrifuge tubes each containing 20×10^6 macrophages were arranged in four rows of three. The tubes of the first row were to contain no antigen, those of the second row 1 μg of PPD (purified protein derivative of tuberculin) per ml., the third row 10 μg of PPD/ml. and the fourth row 100 μg of PPD/ml. In the first column all four tubes contained macrophages but no lymphocytes. In the second and third columns lymphocytes were added to a level of 3 per cent and 15 per cent respectively relative to the macrophages.

The contents of the tubes were mixed gently, spun at 800 r.p.m. in an MSE bench centrifuge, drained and 0·5 ml. of fresh medium (N Parker 199 containing 200 IU/ml. of penicillin and 100 μg/ml. of streptomycin, 15 per cent foetal calf serum and 4 per cent by volume of 4·4 per cent $NaHCO_3$) or medium containing PPD as mentioned before was added. The packed cells were resuspended, and capillary tubes were filled, spun and cut, and the cell-containing portions were placed in chambers as described by David[2]. The chambers contained the same medium and concentrations of PPD as before. Each chamber received two capillary tubes and at least two chambers were used for each concentration of antigen. After the chambers had been incubated at 37° C for 24 h the area of migration was read and expressed as a percentage of the area achieved by the cells in the same column but without added antigen. Table 1 shows the results obtained on five individuals, three tuberculin positive (that is, a Heaf test of 4 or more) and two tuberculin negative. There is a clear cut delineation between the tuberculin positive and negative individuals in the presence of the larger doses of antigen in the presence of both 3 per cent and 15 per cent of lymphocytes.

The first column of tubes which contains no lymphocytes acts as a control for any direct toxicity of the antigen on the migrating macrophages. The first row of tubes reveals any inhibitory effect resulting from the admixture

* Each reading is the mean of the area of spread in four or six migrations

The reading in each column is the area of migration expressed as a percentage of the area achieved without added antigen. The figures in the first column are a measure of the direct toxicity of antigen on the macrophages.

of cells from two different species. This is not shown in Table 1 in which each migration is shown as 100 per cent for comparison with the other tubes in the same column. It was, however, never sufficiently pronounced to obscure the inhibitory effect of added antigen.

The results presented are merely a small example from a larger study of delayed hypersensitivity to streptococcal and tissue antigens in post-streptococcal states as revealed by migration inhibition.

Ovotransferrin with One Iron Atom

TRANSFERRINS are iron-binding proteins which can carry a maximum of two atoms of iron per mole protein. If a preparation of hen ovotransferrin is incompletely saturated with iron and subjected to isoelectric focusing three main protein fractions are observed[1]. The most acidic fraction (pH_I 5·78) is the protein complex with two iron atoms, and the most alkaline fraction (pH_I 6·73) is the metal-free protein. In the intermediate fraction (pH_I 6·25) iron and protein are present in equimolar amounts and Wenn and Williams[1] suggested that this fraction is a protein complex with one iron atom.

Woodworth, Tan and Virkaitis[2] suggest, however, that the intermediate isoelectric fraction represents a dimer composed of one molecule each of metal-free protein and iron-saturated protein. According to their interpretation of gel filtration experiments the intermediate isoelectric fraction is a labile dimer and on polyacrylamide gel electrophoresis at pH 7·5 it apparently dissociates, giving two bands which correspond to the metal-free protein and the protein complex with two iron atoms. They state they have never observed an intermediate band corresponding to a protein complex with one iron atom upon polyacrylamide gel electrophoresis.

Evidence against the proposed dimer is provided by the earlier experiments of Stratil[3]. After addition of increasing amounts of iron to whole egg white, starch gel electrophoresis gave an iron-containing band lying between the bands representing the metal-free protein and the iron-saturated protein. The intermediate band disappeared on complete saturation with iron and all the ovotransferrin was then present as the protein complex with two iron atoms. Stratil[3] suggested that the intermediate band consisted of protein molecules bearing only one atom of iron. We now report experiments on the effect of adding iron to purified metal-free ovotransferrin as determined by starch gel electrophoresis and ultracentrifugation.

Ovotransferrin bearing different amounts of iron can be resolved by starch gel electrophoresis if contaminating metals are removed from the starch powder (Connaught hydrolysed starch, lot 270–1) by washing successively with 0·02 M EDTA and deionized water. Dialysis tubing and glassware were cleaned similarly. Iron, as 100 mM iron-nitrilotriacetate[4], was added to a 2 per cent solution of the metal-free protein in 0·05 M $NaHCO_3$. Starch gel electrophoresis at pH 8·6 illustrated (Fig. 1) that in the course of converting the metal-free protein into the fully saturated iron-transferrin complex an intermediate band exists. It seemed likely that this band would correspond to the intermediate fraction observed in isoelectric fractionation experiments[1].

Isoelectric fractionation was therefore performed on a partially iron saturated preparation of ovotransferrin as described previously[1] and the intermediate fraction (pH_I 6·25) was isolated, dialysed against deionized water (NH_4OH added to pH 9) to remove ampholytes and sucrose, and finally lyophilized. The pink coloured powder was dissolved in 0·05 M $NaHCO_3$ and examined by starch gel electrophoresis with markers of metal-free ovotransferrin and iron-saturated ovotransferrin. Fig. 2 demonstrates that the isolated fraction gives one main band whose mobility is intermediate between those of the two marker proteins; it also contains a small amount of the fully saturated protein. The electrophoretic mobility of the intermediate fraction in starch gel suggests that its molecular weight is not twice that of the marker proteins, for it would then be expected to move more slowly.

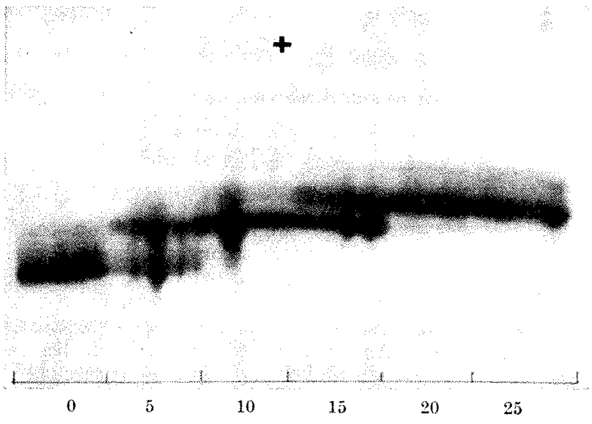

Fig. 1. Starch gel electrophoresis of ovotransferrin in the discontinuous buffer system of Poulik[7]. 11 mg of metal-free ovotransferrin was dissolved in 0·5 ml. 0·05 M $NaHCO_3$. Successive additions of 5 μl. of 100 mM iron-nitrilotriacetate were made and samples were removed for electrophoresis. The addition of 20 μl. of iron-nitrilotriacetate resulted in complete saturation.

In sedimentation experiments, batches of metal-free ovotransferrin dissolved in different buffer solutions

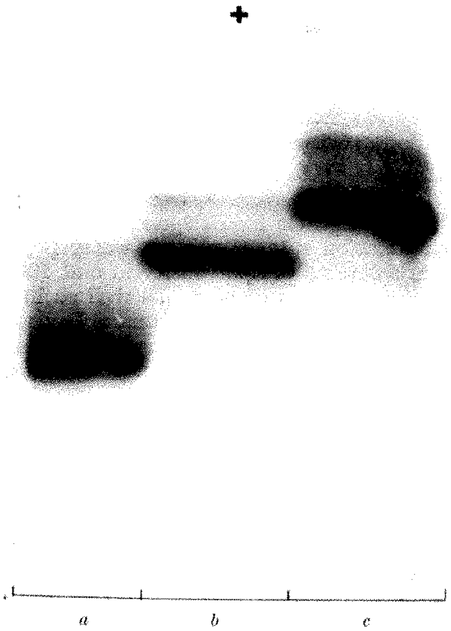

Fig. 2. Starch gel electrophoresis. Samples *a* and *c* are iron-free ovotransferrin and fully iron saturated ovotransferrin, respectively. Sample *b* is the intermediate band recovered from the isoelectric column.

were divided into several aliquots which were then titrated with 100 mM iron-nitrilotriacetate to give different degrees of iron saturation, estimated from the $A_{470\text{ nm}}$. In all cases the peaks were allowed to migrate at least half-way across the cell and they showed no heterogeneity. In the case of the half saturated and wholly saturated protein the absorption pattern of the sedimenting material (as measured with an interference filter at 460 nm) coincided with the peak observed in the Schlieren experiments. In addition, in all experiments the whole of the protein could be accounted for refractively. After removal from the cell the samples showed no increase in iron content, as judged by the $A_{470\text{ nm}}$. The sedimentation coefficients observed in three experiments are given in Table 1. In experiment 2, the buffer was the same as that used for starch gel electrophoresis. There is no increase in the sedimentation coefficient at half saturation which might have suggested the presence of a dimer. In all cases the concentration dependence of the sedimentation coefficient was greater for the fully iron-saturated protein than for the metal-free protein, which agrees with the finding by Fuller and Briggs[5] that iron-transferrin has a greater axial ratio than the metal-free protein.

Table 1. SEDIMENTATION COEFFICIENTS OF OVOTRANSFERRIN SATURATED TO DIFFERENT EXTENTS WITH IRON

Buffer	Per cent iron saturation 0	25	50	75	100
Imidazole-HCl (0·05 M), NaCl (0·05 M), *p*H 6·8	5·1	5·0	4·9	4·8	4·9
Tris-citrate (0·076 M), *p*H 8·6	4·6	—	4·9	—	4·8
Tris (0·075 M), $NaHCO_3$ (0·05 M), HCl, *p*H 8·6	4·8	4·8	4·6	4·5	4·8

The sedimentation coefficients relate to zero protein concentration at 19° in the quoted buffer solutions.

The results of starch gel electrophoresis and ultracentrifugation thus support the earlier proposal[1] that the intermediate fraction observed during isoelectric fractionation is a transferrin complex with one iron atom. This implies that iron atoms are distributed among the metal-binding sites on the protein in an essentially random manner[1,6,8] and it is contrary to the view that the metal atoms bind only in pairs to the protein[4,9,10]. Many authors[1,4,6,8–10] have apparently assumed that a random distribution of metal atoms between the binding sites could only arise if the dissociation constants for the first (K_1) and second (K_2) metal atoms were approximately equal. K_2 has been variously reported to be less than K_1 (ref. 11), approximately equal to K_1 (ref. 6) or much greater than K_1 (ref. 9). It is clear, however, that the binding is effectively irreversible at alkaline *p*H (dissociation constant $\simeq 10^{36}$ M; ref. 6), and it has been shown[12] that no exchange of iron between transferrin molecules occurs at *p*H 7·3 in the absence of chelating agents. We suggest that the iron atoms are randomly distributed on the binding sites, which reflects only the availability of these sites, and we cannot draw conclusions as to the relative values of the dissociation constants.

Absence of Dimers and Nature of Iron Binding in Transferrin Solutions

A CONTROVERSIAL question in the chemistry of the transferrins is whether the two specific sites of the proteins bind metal ions pairwise or randomly. Equilibrium dialysis studies by Aasa *et al.*[1], in which care was taken to show that true equilibrium had been achieved, indicated that the stability constants for the sites were virtually identical; this suggested that the binding sites were equivalent and non-interacting. This work was corroborated by studies using the techniques of moving boundary electrophoresis[2] and isoelectric focusing[3]. In each of these studies, three species of transferrin were recognized and it was suggested that these represented molecules containing nought, one or two iron atoms. This assignment has been challenged by Woodworth *et al.*[4], who argued that the species with intermediate electrophoretic mobility or intermediate isoelectric point was really a dimer composed of molecules devoid of iron and molecules containing two iron atoms. This alternative interpretation was taken as supporting the earlier contention of Woodworth based on kinetic studies that iron atoms bind to transferrin only pairwise, and that solutions of transferrin less than fully saturated with iron would contain only two separable species of protein molecules, those without any iron and those with two iron atoms per molecule[5].

The existence of dimers in protein solutions is accessible to direct experimental investigation. We have used three independent methods to search for their presence. Because Woodworth *et al.*[4] have argued that dimer formation is facilitated in solutions at lower than neutral *p*H, we have carried out sedimentation equilibrium[6] and sedimentation velocity studies in solutions of transferrin half saturated with iron (added as the nitrilotriacetate

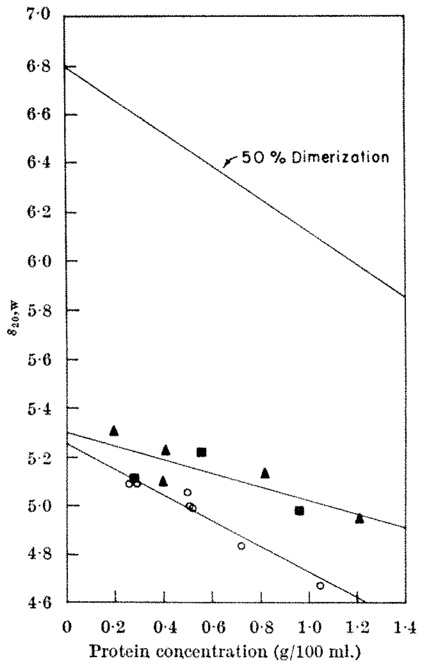

Fig. 1. Sedimentation velocity of apotransferrin in 0·1 M NaCl, *p*H 6·7 (○); 1 : 1 Fe–transferrin in cacodylate buffer, *p*H 6·7, ionic strength 0·1 (■); and 1 : 1 Fe–transferrin in 0·1 M NaCl, *p*H 6·7 (▲). The uppermost line is that calculated for 50 per cent dimerization.

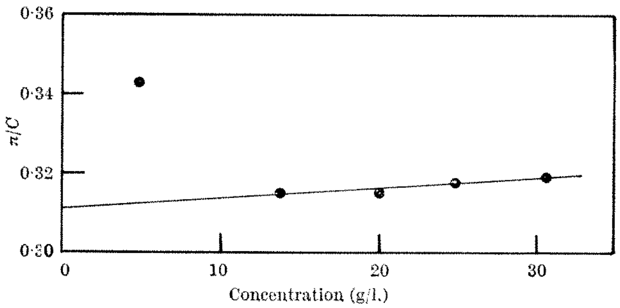

Fig. 2. Osmotic pressure (in cm of saline) in solutions of transferrin 48 per cent saturated with Fe^{3+}, measured by a Hewlett–Packard model 503 high speed membrane osmometer operating at 25° C. The solid line represents a least-squares fit to the data points, omitting the point at lowest concentration which deviates appreciably from the line because of the increased likelihood of experimental error in this region. The number average molecular weight at zero concentration is 80,600 daltons; taking into account the point at lowest concentration would lower this value to 74,700.

complex) in cacodylate and in saline buffers of ionic strength 0·1 and *p*H 6·7. This is the buffer system in which three species of transferrin molecules were recognized by moving boundary electrophoresis; the species of intermediate mobility which Woodworth *et al.*[4] suggested was the dimer form of transferrin was the predominant component at half-saturation. The results of the ultracentrifugal studies are given in Table 1 and Fig. 1. The negative regression in the plot of $s_{20,w}$ against concentration is characteristic of non-aggregating systems. The values of $s^0_{20,w}$ provide additional evidence that no detectable dimer is present. The molecular weight of 78,500 obtained for the half-saturated preparation is that of the monomeric species (K. G. M., W. F., A. C. Cox and C. Tanford, submitted for publication).

Results of osmotic pressure measurements in solutions of transferrin 48 per cent saturated with iron at *p*H 6·2 in 0·15 M NaCl are given in Fig. 2. The molecular weight of 80,600 daltons obtained by extrapolation to zero concentration is in good agreement with the values obtained from sedimentation measurements. Again, there is no evidence indicating the existence of dimers.

Table 1. ULTRACENTRIFUGAL STUDIES OF HUMAN SERUM TRANSFERRIN

Preparation	$s^0_{20,w}$	Molecular weight based on: Sed. velocity*	Molecular weight based on: Sed. equilibrium
Apotransferrin† (0·1 M NaCl, *p*H 6·0)	5·25	77,700	
1 : 1 Fe transferrin (0·1 M NaCl, *p*H 6·7, or 0·1 M sodium cacodylate, *p*H 6·7)	5·30		78,800
2 : 1 Fe–transferrin (0·1 M NaCl, *p*H 6·5)			76,600

* The partial specific volume ($\bar{v}$) for this calculation is taken as 0·725 cm^3/g (K. G. M., W. F., A. C. Cox and C. Tanford, submitted for publication; †, the data on apotransferrin are also taken from this source).

Finally, the magnetic field dependence of the nuclear magnetic relaxation rate of solvent water protons[7] was measured in solutions of apotransferrin and 100 per cent saturated transferrin as controls, as well as in a 50 per cent saturated transferrin solution and a 1 : 1 mixture of the control samples. The circles and crosses in Fig. 3 show the data for the latter two samples. The solid line through the points is the result predicted if no dimerization occurs; it is obtained by averaging results for apotransferrin and fully saturated transferrin (Fig. 1 of ref. 7). The upper solid curve is the result predicted for 100 per cent dimerization, assuming that the amount of water bound per mg of protein does not change, that the accessibility of water to the iron sites does not change, and that the geometric factors that affect the rotatory Brownian motion of the dimer are the same as those for the monomer. Given the magnitude of the difference between the two solid curves, it is highly unlikely that errors in these assumptions would produce a result which agrees with the present data as well as does the curve predicated on the assumption of no dimerization. The curves for transferrin brought to 50 per cent saturation with Fe^{3+} by the simple addition of metal, and equimolar mixtures of apotransferrin and fully saturated transferrin, coincide, with no detectable evidence of dimerization in either.

We therefore conclude that dimer formation does not occur in transferrin solutions at any degree of saturation with iron, and that the existence of three types of transferrin molecules by a moving boundary electrophoresis[3], starch gel electrophoresis[8], and isoelectric focusing[4] reliably indicates that iron atoms do not bind to transferrin molecules in pairwise fashion.

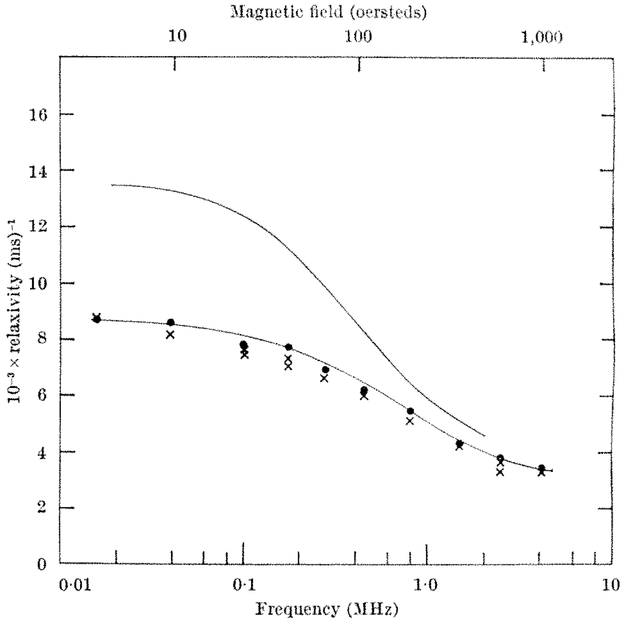

Fig. 3. Nuclear magnetic relaxation dispersion in transferrin solutions. Total protein concentration 4·9 per cent; 0·1 M KCl, *p*H 7·6. Transferrin 50 per cent saturated with Fe^{3+} (●); equimolar mixture of apotransferrin and 100 per cent saturated transferrin (×). The lower solid curve is the result anticipated for both samples in the absence of dimerization. The upper curve is the result anticipated for 100 per cent dimerization for one particular set of assumptions (see text).

Oxidation of Haemoglobin by Oxygen in Light: Possible Role of Singlet Oxygen

THE transformation of oxyhaemoglobin (HbO_2) to methaemoglobin (Hb^+) involves an electron transfer whereby the ferrous haem iron is oxidized, with the simultaneous reduction of the oxidant, oxygen. In the event of the O_2 being fully reduced (to H_2O) in the process[1], 1 mole of HbO_2 will be expected to release 0·75 mole of O_2, for an electron donated by the ferrous iron can reduce only a quarter of the oxygen released by the iron in going to the trivalent state. In a study of the conversion of oxymyoglobin to metmyoglobin, however, George and Stratmann[2] have reported the consumption of 2·5 moles of O_2 for each mole of haem iron oxidized and attributed the excess to unspecified electron donor groups in the protein moiety.

We have investigated whether the excess oxygen consumption might be linked to a photochemical reaction. We used human HbO_2 in conditions similar to those described by George and Stratmann (*p*H 5·6, 30° C); the test reactions were carried out under moderately strong incident white light, those reacted in darkness serving as blanks. The results indicate that a photodynamic effect is indeed involved; the excess consumption occurred only in light and the dark reaction gave rise to the release of nearly the expected quantity of gas (Fig. 1). The optical absorption spectrum of Hb^+ obtained under illumination exhibited small but significant differences from that of Hb^+ obtained either in the dark or prepared by ferricyanide oxidation. In the aquo spectrum (*p*H 6), two new bands at about 535 nm and 565 nm (low-spin type, Brill and Williams[3]) were evident, with a simultaneous decrease in intensity of the charge transfer bands (630 nm and 500 nm). The Hb^+ obtained by either method was reduced and the oxygen binding properties of each sample were then compared with those of native haemoglobin. The recovered haemoglobins displayed more or less significant differences from the normal protein (diminution of Hill coefficient, increase in oxygen affinity), but the protein obtained from Hb^+ produced in the light always showed the greatest difference.

The chemically active agent seems to be the oxygen molecule bound in HbO_2 at a given instant, as distinct from free O_2 in solution: experiments performed with Hb^+CN^- in identical conditions showed hardly any consumption of oxygen. The bound oxygen in HbO_2 may therefore be somehow activated by light energy absorbed by the haem chromophore. We believe that singlet oxygen may be involved, produced through photosensitization by the haem, according to the reaction

$$\text{Haem}-{}^3O_2 \overset{+h\nu}{\rightleftarrows} {}^1\overset{*}{\text{Haem}}-{}^3O_2 \rightarrow \text{Haem}+{}^1\overset{*}{O}_2$$

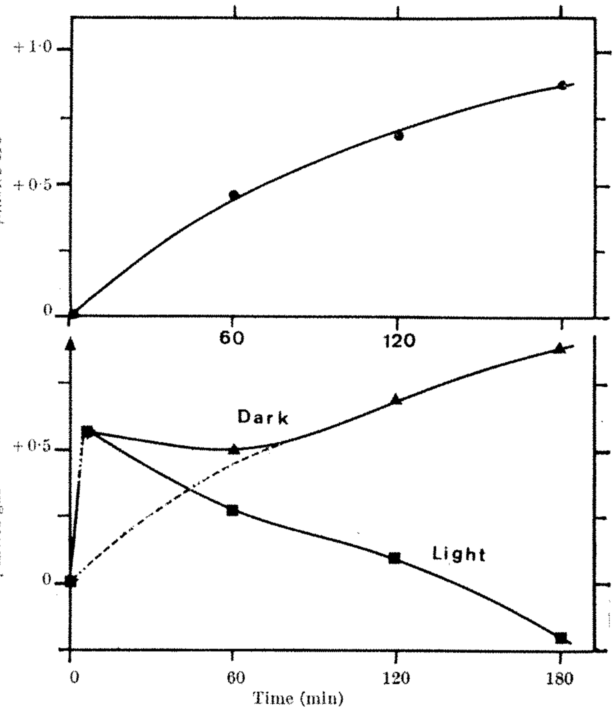

Fig. 1. Top: Net amount of gas evolved or absorbed during the oxidation of HbO_2 in the dark and in light (averaged from three independent experiments). Phosphate buffer (0·65 M, *p*H 5·6), 30° C. Initial concentration of HbO_2, 0·8 mM (haem). Bottom: µmoles gas evolved or absorbed. The initial jump is believed to result from the release of bound CO_2 on lowering the *p*H of oxyhaemoglobin from 6·8 to 5·6. This gas is absorbed by a solution of NaOH placed in the centre well of the Warburg vessel.

Haems are neither fluorescent nor phosphorescent and thus cannot normally sensitize $^3O_2$, but their close proximity to bound O_2 may in some manner compensate for the short lifetime of the excited state. The excited singlet molecular oxygen in its $^1\Delta g$ state is a high energy oxidant with an abnormal lifetime[4], which can act as an energy carrier between a sensitizer and an oxidizable substrate. One may expect long range oxidative action by the continual release of $^1O_2^*(^1\Delta g)$ from its combined state, as is indeed the case in a solution of HbO_2.

Some experimental support for this hypothesis has been obtained from a study of the properties of Hb^+ prepared by the action of chemically generated $^1O_2^*$ on HbO_2. The excited species was generated in a separate compartment ($NaOCl+H_2O_2$) and was transferred to the HbO_2 solution by a stream of nitrogen. The absence of gaseous Cl_2 and the presence of $^1O_2^*$ in the gas stream were ensured by appropriate tests. A solution of HbO_2 treated for a few minutes with $^1O_2^*$ exhibited all the same modified properties as result from the action of oxygen under prolonged illumination. Although this is not unequivocal proof that the active oxidizing agent is identical in each case, it supports the possibility that singlet oxygen, produced by photosensitization through the haem chromophore, is responsible for the extra consumption of oxygen in the oxidation of HbO_2 under illumination.

Chemically generated $^1O_2^*$ might be useful for studying modification in enzymes and other systems, normally achieved through photosensitization[5]—the equivalent of a "photodynamic effect without light".

Glucose-6-phosphate Dehydrogenase Isoenzymes in Blood Cells

THE enzyme glucose-6-phosphate dehydrogenase (G-6-PD) exists in several different forms (isoenzymes) in the human erythrocyte, each apparently determined by a different allele at a single locus on the *X* chromosome. The structural differences between the isoenzymes lead to different enzymatic activities and often render them separable by gel electrophoresis.

Studies on G-6-PD using enzymatic methods[1] and cytochemical techniques (unpublished results of L. A. R., D. S. and T. Menashe) showed that both normal and G-6-PD deficient erythrocytes of various age groups differ in their enzymatic activity. Because these findings imply that the changes in the enzymatic pattern are a function of age, we decided to check the isoenzyme distribution of G-6-PD in cells of different age groups taken from persons with normal G-6-PD levels.

Heparinized venous blood was used. Thrombocytes and leucocytes were separated by differential centrifugation[2] and the erythrocyte fraction was freed from residual leucocytes by centrifugation and removal of the upper layer. The red blood cells were separated into different age groups according to their density using phthalate esters as the separating medium[3]. The red cells were haemolysed by dilution with aqueous solution of β-mercaptoethanol (1·4 to 14 mM) and/or NADP (0·01 to 1 mM). Leucocytes and thrombocytes were lysed by repeated freezing and thawing. Polyacrylamide gel disc electrophoresis was done using the method of Davis[4] without the sample gel. Staining of the gels to detect G-6-PD activity was performed by the method of Hori *et al.*[5].

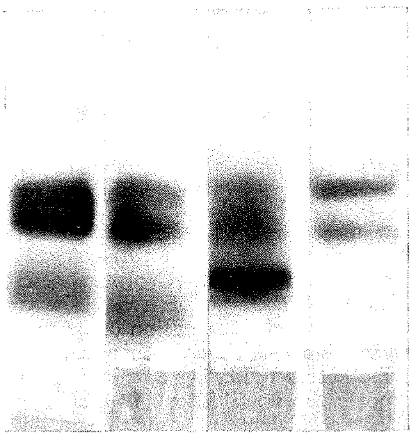

Fig. 1. Polyacrylamide gel disc electrophoresis of red blood cell lysates of different age groups. *a*, Haemolysate of unfractionated erythrocytes; *b*, lysate of "old" red blood cells; *c*, lysate of "young" erythrocytes having three G-6-PD bands; *d*, leucocyte lysate.

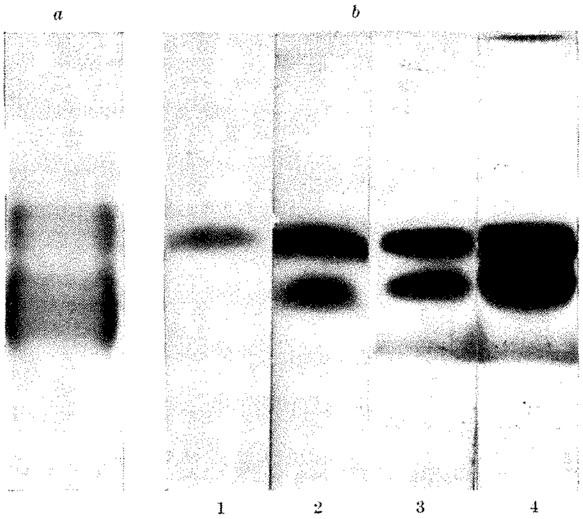

Fig. 2. *a*, Electrophoretic pattern obtained with 0·1 mM NADP added to the gel and upper buffer. Unfractionated erythrocyte lysate was used; *b*, changes in the observed electrophoretic pattern as a function of the amount of applied lysate. Unfractionated lysate was used. 1, 10 μl. lysate; 2, 15 μl. lysate; 3, 20 μl. lysate; 4, 50 μl. lysate.

Sixty-two people were studied, twenty-nine males and thirty-three females, all of whom had normal G-6-PD activity. Disc electrophoresis of the erythrocyte lysates showed a pattern consisting of two enzymatically active bands. The same electrophoretic picture was obtained using haemolysates of "young" cells, "old" cells and unfractionated erythrocytes (Fig. 1). The G-6-PD activity measured spectrophotometrically was, however, higher in the "young" cells than in the "old" ones[1,6].

In most of the cases studied, the band III was the first to appear during staining. This slow band had the same electrophoretic mobility as the haemoglobin A_2 zone. The second band, II, was present in all the cases, but in most of them it seemed to be less active than the slow band III and a longer incubation time was necessary for it to be seen (Fig. 2*b*, 1 and 2). No changes in the electrophoretic pattern were observed between males and females. In three out of the sixty-two cases studied, a third band (I) having G-6-PD activity was visible (Fig. 1*c*) which had a faster electrophoretic mobility and migrated together with the haemoglobin A zone. This band could be found only in the "young" erythrocyte fraction and its enzymatic activity was rather weak compared with the other two active bands. While 90 min incubation in the reaction medium was enough to stain the two slow bands, additional incubation of 12–20 h in water was required before the third band became visible. In all cases, electrophoresis of leucocyte and thrombocyte lysates showed two active bands similar to those found with red cell lysate. No evidence was found for the fast band (I) in these cells.

Application of varying amounts of the different haemolysates to the polyacrylamide gel has shown that an optimal amount of G-6-PD activity should be used (Fig. 2*b*). The use of too small an amount will show the presence of only one band while the use of an excessive amount of activity will cause the two active bands to merge and to appear as one broad band.

Because these electrophoretic patterns were unexpected, it was suspected that they could be electrophoretic artefacts. It was reported[7] that an additional G-6-PD active band could result from disulphide bridge formation between G-6-PD and some serum proteins. Addition of β-mercaptoethanol to the haemolysate, in concentrations ranging from 0·028 M to 0·0028 M, failed to change the electrophoretic pattern, though it should have been sufficient to dissociate any such aggregates. Addition of NADP, in concentrations ranging from 2 mM to 0·02 mM, to the haemolysates, in the presence or in the absence of β-mercaptoethanol, also had no effect on the electrophoretic pattern. When the polyacrylamide gel concentration was varied between 7 and 12 per cent, all G-6-PD active bands were retarded to the same extent, suggesting that all three bands have the same molecular size.

Addition of NADP to the upper buffer and the gel itself has resulted in a further resolution of the bands. The upper band (III) was resolved into two subfractions and the second band (II) was resolved into three (Fig. 2*a*). The presence of NADP was found to increase the sensitivity of the reaction so that small amounts of activity could be detected in this way, which would have been unnoticed in the absence of NADP. The significance of this further separation is under investigation at present. This technique could be used in cases of G-6-PD deficiency where the enzymatic activity is weak and would not be detected by the regular method.

Previous findings[1] that G-6-PD activity declines with ageing of the cell have been confirmed for a particular isoenzyme[1] that is present only in the "young" erythrocytes and absent from more mature cells. This may suggest a change in the enzymatic profile of the cells with ageing, caused by the gradual disappearance of the more labile forms of G-6-PD at an earlier stage.

It has been suggested that in cases of G-6-PD deficiency, there is a point mutation that increases lability and accelerates the rate of destruction of the enzyme[8]. This hypothesis is supported by the finding that in cases of severe G-6-PD deficiency showing no activity in the ordinary spectrophotometric assay, two active bands (Fig. 2*a*) were demonstrated in "young" erythrocytes when NADP was added to the gel and the upper buffer to increase the sensitivity of the reaction.

Pheromone may induce Brood Tending in the Fire Ant, *Solenopsis saevissima*

OUR observations of laboratory colonies of the fire ant, *Solenopsis saevissima* (F. Smith), suggest that care of the immature forms by the workers might be influenced by secretions from the immature forms. Recognition of the immature forms and their care by workers might thus be associated with these secretions. Watkins and Cole[1] noted that worker army ants, *Neivamyrmex opacithorax* Emery, were attracted to secretions of their larvae and pupae. This letter presents the results of studies we have made on the response of worker fire ants to extracts of their brood.

In the first test, the entire brood from one colony of fire ants was collected, and an extract was prepared from samples of all types of immature forms by homogenizing the pooled forms in cold hexane. The clear extract was then poured over corn cob grits (ground corn cobs, twelve to thirty mesh) which were mixed until the hexane evaporated. The treated and untreated grits were placed on the foraging platform that serves our clear plastic nests. The ants immediately began picking up the treated grits and carrying them to the nest, so in a relatively short time (about 1 h) they had removed all the treated grits and left all the untreated grits. The same response was obtained when clay granules or pieces of paper were treated. Our most important finding, however, was that the ants placed the treated material with their brood within their nest. Later, when we repeated the trials four times with grits, three times with clay granules and three times with pieces of paper, the treated materials were always harvested, but 6 to 24 h later the ants had removed them from the nest to the refuse pile. Ants did not pick up grits treated with hexane alone.

After the preliminary tests, we determined the reactions of the ants to extracts from the various types of immature forms, worker larvae, worker pupae, sex larvae, or sex pupae and to dilutions of these extracts. In this test, 2 g of each form was collected from field colonies and homogenized by hand in a tissue grinder in 2 ml. of hexane. Then the extracts were poured over about two hundred corn cob grits each and evaporated as before. Also, dilutions of 1 : 1, 1 : 10 and/or 1 : 100 of each extract were prepared by appropriate dilution and evaporated on similar numbers of corn cob grits.

The worker ants harvested grits treated with extracts of worker or sex larvae, but they did not harvest any grits treated with extract of worker or sex pupae. When the extract of sex larvae was diluted, workers harvested all grits treated with dilutions of 1 : 1 and 1 : 10 and harvested some grits treated with a dilution of 1 : 100; however, when the extract of worker larvae was diluted, the harvesting of the 1 : 1 dilution was only partial, and no harvesting of grits treated with greater dilutions occurred. Similar results were obtained with ant colonies in soil nests; however, we did not attempt to locate the place where the ants deposited the treated grits in these nests.

In all our studies, the worker ants found and carried the treated grits to their nest, groomed the treated grits, rubbed them with their antennae and palpi, and generally appeared to care for them as they did their brood. In one test, workers carried brood from the nest and placed it with the treated grits on the foraging platform. Moreover, when a colony was disturbed by a sharp tapping that caused an alarm reaction, the worker ants picked up the treated grits and ran about with them in the same manner as they normally do with brood. Workers from subcolonies that had no queen or brood also collected treated grits and returned them to their nest.

Because our method of extraction removed lipids from the brood and because worker ants are greatly attracted to fats and oils, the attraction of the grits that we had noted might be a food response. We therefore tested the response of worker ants in three nests to grits treated with vegetable oil. In two of these colonies, the ants removed the oil from the grits but did not carry the grits into the nests. In the third colony, some grits were carried into the nest, but they were placed apart and separate from the brood. It thus seems that the reaction of the ants to the extract of immature forms was not a food response.

The action of the worker ants of *S. saevissima* in locating, transporting and caring for inanimate objects treated with extracts of brood and placing these treated objects with their brood demonstrated that a pheromone (or pheromones) is associated with recognition and brood tending. The attractant was present in both worker and sex larvae, but not in pupae. This lack of a pheromone(s) in pupae in these preliminary tests does not necessarily preclude its occurrence, however, because we may not have extracted a sufficiently large sample. The removal of the inanimate objects to the refuse piles within 24 h after the introduction into the brood or nests seems to indicate that the pheromone(s) had dissipated.

Function of the Gravity Receptor of *Octopus vulgaris*

MICROANATOMICAL[1-4] and electrophysiological[5-8] investigations support the hypothesis that the sensory elements of the statocysts of Crustacea and of the vertebrate vestibular endorgans are stimulated adequately by lateral displacement (shear) exerted by the statolith or statoconial membrane. Behavioural findings agree with this kind of statocyst stimulation; for example, equilibrium reactions of fish[9] and Crustacea[10], and counterrolling of eyes and perception of vertical in humans[11-15]. These reactions are influenced by both parameters which determine shear, that is to say, they depend as much on the direction (which can be changed by tilting the subject) as on the magnitude of the gravito-inertial force.

In the octopus statocyst, the oval shaped sensory epithelium (macula) of the gravity receptor is oriented vertically in the normal position of the animal[16]; the macula planes of the left and right statocyst subtend an angle of 90 degrees open to the front. The sensory elements of the macula show a clear morphological polarization: the basal feet of all kinocilia of one cell project radially away from the centre of the macula[17-19].

We investigated the counterrolling of the eyes of *Octopus vulgaris*. This compensatory reaction depends on the function of the statocysts[20]. It was recorded in seventy-two specimens at normal gravity (experiment *A*) and in seven specimens at increased magnitude of gravito-inertial force in a centrifuge (experiment *B*). The animal was mounted with its arms firmly fixed together on a board which could be rotated in the sagittal plane (except in experiment *A*(4)), that is, around a transverse axis of the animal, using the eye as a pivot point. Rotation was carried out with a motor with constant speed of 2·4 degrees/s. The position of the pupil was recorded photographically every 20 degrees. In Fig. 1, the deviation of the pupil slit from an animal fixed reference line is plotted against the animal's position to gravity. *A*(1) The two curves of each diagram refer to forward and backward rotation of the animals. Those of Fig. 1(1), (2) and (4) demonstrate a hysteresis effect (B.-U. B., in preparation). *A*(2) In thirty-eight specimens the function of one gravity receptor was abolished by carefully displacing the statolith completely from the macula. The curves are of the same shape as those of normal animals, but the amplitude is diminished by about 50 per cent (compare Fig. 1(1) with Fig. 1(2)). No difference could be observed either in the movements of the left and right eye or in the eye movements of left and right operated animals (B.-U. B., in preparation). Unilateral extirpation of the whole statocyst sac resulted in similar curves, but a small difference in the amount of counterrolling of both eyes was observed during the first days after operation (B.-U. B., in preparation). *A*(3) After bilateral extirpation of the whole statocyst sac and after bilateral displacement of the statoliths no counterrolling of the eyes was observed (B.-U. B., in preparation). *A*(4) In twelve unilaterally operated animals, the counterrolling was recorded in the following positions of the remaining macula plane relative to the rotation axis: (*a*) 45 degrees, that is, rotation around the transverse axis of the animal as in experiment *A*(1) (Fig. 1(2)); (*b*) parallel (Fig. 1(3)); or (*c*) perpendicular (Fig. 1(4)). The animals with 45 degree and perpendicular oriented macula showed almost normal counterrolling. In the animals with parallel oriented macula, however, the counterrolling had ceased almost completely.

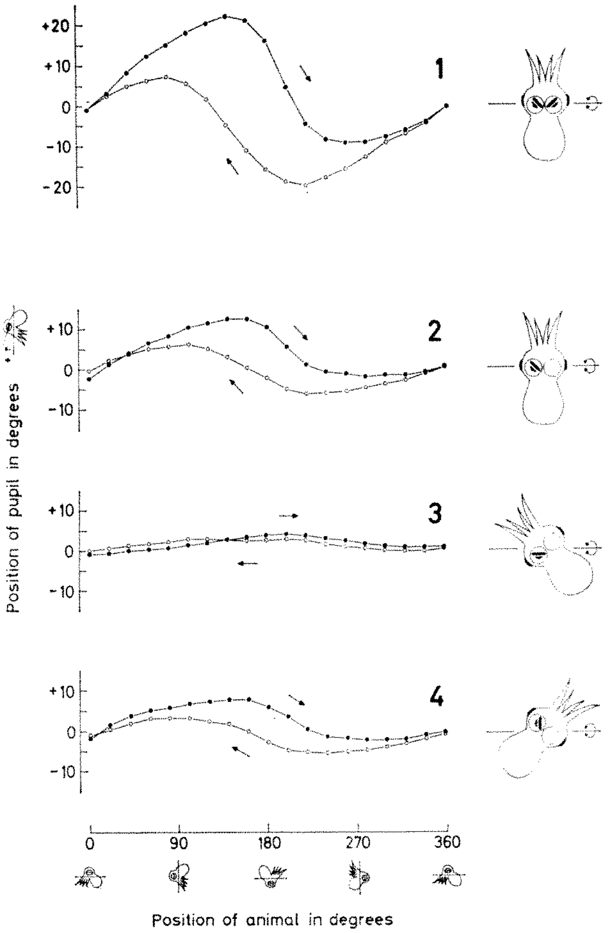

Fig. 1. Compensatory counterrolling of the eyes of octopus as a function of body position to gravity. Each curve represents the averaged data of twenty-four records on the same twelve animals. Ordinate: angle between pupil slit and animal fixed reference line (which is horizontal in the normal position of an octopus); abscissa: angle of tilt from the normal position. Tilt was performed around rotation axes as indicated in the symbols on the right hand side. Each symbol shows an octopus seen from above, with statocyst(s), macula(e) and statolith(s). Arrows on the curves refer to direction of tilt. The four diagrams refer to the results from: 1, normal animals; 2, unilaterally operated animals, rotation axis in a 45 degree position to the macula plane, that is, rotation axis transversal to the animal (as in 1); 3, unilaterally operated animals, rotation axis parallel to the macula plane; 4, unilaterally operated animals, rotation axis perpendicular to the macula plane.

B. Normal and unilaterally operated animals were investigated in a centrifuge at different body positions at magnitudes of gravito-inertial force from 1·0*g* to 1·5*g* (in our experiments centrifugation affected only the magnitude, not the direction of the force with respect to the animal). As can be seen from Fig. 2, the magnitude of the gravito-inertial force did not influence the counterrolling of the eyes.

These results lead to the following conclusions. (1) The counterrolling of the eyes of octopus depends on the function of the statolith organ of the statocyst sac (experiment $A(3)$). It does not seem to be affected by sensory elements of the cristae which are known to be stimulated by angular acceleration[21]. This view is suggested by the absence of angular acceleration in our experiments and also by the results of experiment $A(4)$ (Fig. 1(3)). (2) The effect of both gravity receptors on the counterrolling is additive (compare Fig. 1(1) and Fig. 1(2)). Similar results have been obtained in fish[9] and Crustacea[10]. (3) The ocular counterrolling alters as a function of the direction of shear of the statolith (Fig. 1(4)). (4) The counterrolling is not affected, however, by the magnitude of shear which has been altered either by change of tilt position of the macula (Fig. 1(3)), or by change of magnitude of gravito-inertial force (experiment B).

Although the eye counterrolling in octopus is not affected by the amount of shear, shear (lateral displacement) may nevertheless be considered as the stimulating force for the sensory elements of the macula. The topographical arrangement of the maculae implies that with change of position of the animal, for instance, around a traverse axis, the direction of the shear force of the statolith moves on the macula like a hand on a clock-face. The current theory of stimulation of sensory cells bearing kinocilia[6-8,18,19] assumes that the excitation of a sensory cell increases when the kinocilium is displaced towards the basal foot and decreases when displaced in opposite direction; the excitation varies as a function of the cosine of the angle of projection of the basal foot relative to the direction of the stimulus, that is, of statolith shear. In octopus this would result in a specific pattern of excitations of all sense cells on the macula. It can be characterized by a maximum of excitation of the cells which are oriented with their basal feet in the direction of statolith shear. From the direction of maximum stimulation, the excitation of the cells in both directions decreases as a function of the cosine of the angle of the basal foot orientation to the direction of statolith shear.

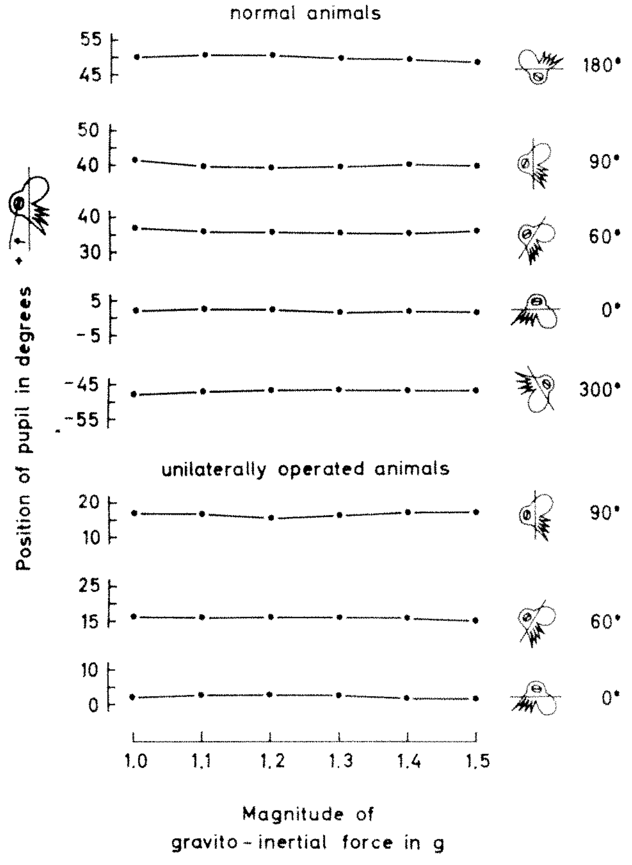

Fig. 2. Compensatory counterrolling of the eyes of octopus as a function of the magnitude of the gravito-inertial force at the body positions indicated on the right hand side. Each curve consists of single measures on one animal. Ordinate: angle between pupil slit and animal fixed reference line; abscissa: magnitude of gravito-inertial force.

As can be concluded from our data, only the angular orientation of the excitation pattern on the macula, that is, its rotatory shift with respect to macula fixed coordinates, affects the counterrolling of the eyes of octopus. This is irrespective of the overall amount of excitation as affected, for instance, by shear magnitude. Thus these findings reveal a principle of statocyst function which seems to be different from that described for Crustacea and vertebrates.

The experimental work was done at the Stazione Zoologica, Naples, and at the Max-Planck-Institut, Seewiesen.

Eye Ultrastructure, Colour Reception and Behaviour

IN many animals—both vertebrates and invertebrates—certain innate behavioural patterns (in, for example, feeding and sexual behaviour) are preferentially elicited by stimuli with specific qualities (such as colour of visual stimuli) which act as so-called releasers. An initial "tuning" of a stimulus as a releaser may take place at the receptor level (as with receptor specificity in night moth olfaction). One might ask whether, in some cases, further mechanisms may exist in the transmission of energy to the receptors which enhance selectively that quality of the stimulus which characterizes it as a releaser.

The present study shows that, in a diurnal butterfly (*Heliconius erato*), such a mechanism in the transmission system to the photoreceptors selectively enhances the stimulating effect of light within a certain wavelength region, of which the hue represents the releasing factor for a well described innate behaviour pattern.

The compound eyes of many invertebrates (such as the crayfish and butterfly), as well as the camera eyes of several other invertebrates (such as the scallop) and certain vertebrates (such as dog, cat and sheep), are equipped with an array of various types of specialized structure behind the photoreceptors. The array acts as a mirror, reflecting light back to the receptors, and thus increases the chance of capturing extra quanta. When the compound eye of a dark-adapted night moth is illuminated, such a reflexion ("glow") can be seen in a great many ommatidia in the part of the eye facing the

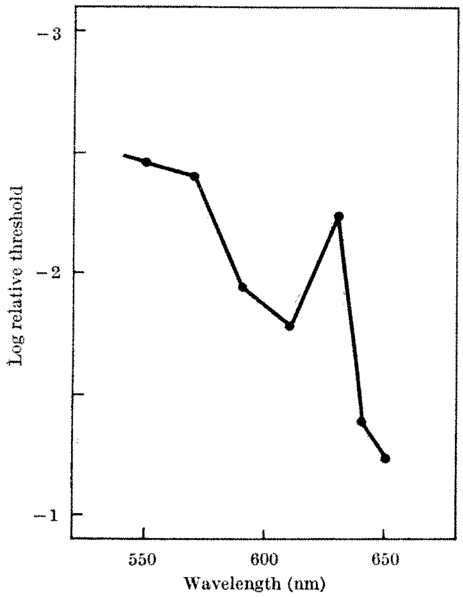

Fig. 1. Log relative threshold of electrical response from compound eye of *Heliconius erato* to monochromatic light between 550 and 650 nm (duration of stimulus 0·2 s).

observer[1]. This non-selective reflexion in night moths comes from the tracheolar layer around and behind the proximal ends of the receptors[2]. In diurnal butterflies a discrete coloured glow can be seen with the aid of the ophthalmoscope, which makes possible observation and illumination from the same direction[2]. In recent years, attention has been paid to various microcomponents of the compound eye optic system which may influence the energy transmission to the receptors[3-6]. It has been shown[5-6] that the selective reflexion, expressed in the coloured glow in the diurnal butterfly, occurs in a multi-layered structure of platelets formed by modified taenidia of the tracheoles located behind the receptors. This structure functions as a quarter-wavelength interference filter, reflecting light in its rejection band. It was suggested[5] that these structures, which seem to be characteristic for diurnal butterflies, serve to increase colour contrast.

The behaviour of the diurnal tropical butterfly, *Heliconius erato* has been thoroughly studied by Crane[7], who found that in this species red light—of a colour similar to that of the butterfly's forewing band—is an important releaser in courting behaviour. In our study, therefore, this species was used for ophthalmoscopic, electron microscopic and electrophysiological investigation.

Ophthalmoscopy with white light revealed a red glow, representing selective reflexion of light of the forewing band colour. Comparison with monochromatic light, made by independent observers, showed that the colours of both the glow and the forewing band were in the wavelength range 600–650 nm. Electron microscopy showed the existence of numerous wide, straight tracheoles around and behind the photoreceptors. Calculations based on the dimensions of the taenidial array of these strongly developed tracheoles indicate that this tracheolar system could serve as an interference filter (compare Miller *et al.*[5]) reflecting the red light seen in the glow.

To see whether this reflexion of light in the red band enhances selectively the stimulating effect in the red wavelength region, measurements were made of the intensity of monochromatic light required to elicit a threshold compound photoreceptor response of 50 µV. The eye was stimulated with light of different wavelengths (380–650 nm) by using a prism monochromator (Zeiss *M* 4 *Q* III) and the electrical response was recorded with Ag–AgCl electrodes (diameter of corneal electrode 0·1 mm).

The general shape of the spectral sensitivity curve, which is of less interest in this context, was similar to that described for other insects (for a review, see Burkhardt[8]). Accordingly, the sensitivity decreased between 550 and 650 nm, as seen in Fig. 1. On the slope of the curve towards longer wavelengths, however, there is a pronounced and narrow peak (about 0·5 log units) between 610 and 640 nm. The narrowness of the peak, together with the fact that such a peak has never been obtained in Lepidoptera lacking selective reflexion (such as night moths[9]), make it unlikely that the peak represents a specific photopigment. Because it is localized within a wavelength region corresponding to that of the observed glow, the peak seems rather to result from selective reflexion in the red band caused by the tracheolar system. The peak represents a significant enhancement of the stimulative efficiency.

Our results thus indicate that the reception of a colour cue serving as releaser of an innate behavioural pattern can be selectively enhanced by a specialized mechanism of the visual dioptric system.

Arousal and Information Selection in Short-term Memory

In experiments on short-term memory a subject is typically presented with a list of items such as words or digits and then asked to recall the complete list in order of presentation. This simple paradigm has produced many important findings about the nature of the information-handling mechanism in memory. In most cases, however, the problem of short-term memory is assumed only to involve storage and retrieval of information, and no allowance is made for the subject's freedom to attend selectively to the incoming stream of information. In other words, some of the information presented may never be admitted to storage at all—a possibility that is particularly relevant to recent research[1-4] on the interaction between memory processes and arousal, because we have found[5,6] that arousal is a major determinant of changes in patterns of information selection in visual monitoring tasks. In loud noise, subjects attend more to sources of information of "high priority" and are more likely to disregard sources of less important information.

The findings mentioned above show an interesting relation between arousal, or general level of stimulation, and the length of delay between the presentation of items and their recall. Higher arousal in these studies has been either inferred from larger autonomic responses to particular stimulus words, or produced by carrying out the task in a stimulating environment (in practice, white noise has been used for this purpose). In general, high arousal items are recalled less well immediately after presentation than those associated with low arousal, but are produced more readily in a recall test which is delayed by, say, 24 h. The only present theory to account for these results is based on the concept of "trace consolidation", and has been advanced particularly by Walker and Tarte[2]. This view argues that the presence of a raised state of arousal at the time an item is presented results in a "more active" memory trace, so that when the consolidation process is completed (perhaps the next day) recall is better for these items. To account for the impairment in immediate recall of high arousal items, increased consolidation of the trace is postulated to be incompatible with its retrieval, because the two processes can be regarded as opposite in direction. The effect, that is, relates only to differential consolidation of the input once it has been taken in. In view of our own findings, that the pattern of information selection seems to change with arousal, at least part of the effect may conceivably be the result of differential intake of information.

We are now examining this possibility directly in another series of experiments. The present study, however, deals only with demonstrating changes in input selection in the memory situation with arousal (noise): the simple short-term memory paradigm outlined at the beginning is used. If information selection changes occur in memory just as they occur in monitoring situations when arousal is increased, then we should find that subjects attend relatively less to an irrelevant source of information in noise. To test this, an extra feature is incorporated into the short-term memory situation—the presence of an irrelevant cue. The relative performance of subjects on the relevant and irrelevant parts of the task can then be used to infer any changes in attention distribution under arousal.

Eight slides were made up, each containing a common bisyllabic adjective. The irrelevant cue was that each word could appear in any of the four corners of the screen (two words, in fact, appeared in each corner). The words were presented at a fixed rate of one every two seconds, no two successive slides presenting words in the same location. Subjects were told nothing about the location cue; they were instructed to recall all the words, in correct order, when they observed the blank screen at the end of the series. A sheet was provided with eight spaces in which to write correct responses. After all subjects had completed the relevant task, it was pointed out that the words had, in fact, appeared in different locations, and they were asked to indicate these by putting a cross in the corresponding corner for each of the words they had written down. They were told to guess if they could not remember.

Sixty-eight subjects were tested in groups in one of two experimental conditions: (*a*) "quiet"—a continuous background noise of about 55 dB was present in the testing room, and (*b*) "noise"—the level was 80 dB. Thirty-six subjects were tested in the quiet condition and thirty-two in noise. The noise level remained constant throughout the experiment for each group of subjects. Instructions were given with no noise present.

Three performance measures were taken, as shown in Table 1. For the relevant task, recall was scored by considering (i) both word and order accuracy, and (ii) word accuracy only, ignoring the necessity for words to be in the correct order. The second measure tended, naturally, to give larger scores. Neither measure shows any difference between noise and quiet (both $P > 0{\cdot}05$). There is a tendency, however, for recall in noise to be better when correct order is taken into consideration (this comparison almost reaches statistical significance at $P = 0{\cdot}05$). The difference disappears completely and tends to reverse when order is not considered, implying that subjects in the noise condition attend more to order cues present in the list (links between successive words or direct coding of order for each word). Success on the irrelevant task (recall of locations) was best measured by taking the mean percentage of correct locations as a function of the total number of words correctly recalled (measure (ii) above). This was necessary because the possible number of correct locations is limited by the number of words successfully reported (a subject cannot attempt to recall the location of a word he has not recalled). This measure shows a significant difference between treatments ($P < 0{\cdot}05$). Attention to the irrelevant cue thus occurs less in the noise condition, subjects selecting information more from the relevant task (this is supported by the above observation about order preservation in the recall of the word lists).

Table 1. MEAN PER CENT RECALL OF RELEVANT AND IRRELEVANT CUES IN "QUIET" AND "NOISE"

	Relevant task Percentage of words recalled in correct order	Percentage of words recalled irrespective of order	Irrelevant task Percentage of locations recalled
Quiet ($N = 36$)	43·75	73·12	48·50
Noise ($N = 32$)	54·12	69·00	32·00
Statistical significance	$P = 0{\cdot}055$	$P > 0{\cdot}10$	$P < 0{\cdot}05$

These findings illustrate that changes in the pattern of information selection are a measurable feature of memory situations. It cannot be assumed that all relevant information is taken in equally efficiently in different conditions. There is a tendency for subjects, even in this simple and brief task, to attend to features of the stimuli which are not relevant to efficient performance (as defined by the instructions). This tendency occurs less in situations that are arousing, and there may thus be important consequences for the general applicability of the consolidation theory to the findings on arousal and memory discussed earlier. In particular, it seems likely that at least part of the explanation for these results will involve differences in information intake with high and low arousal. It is also worth noting that immediate recall with high arousal tended to be better in this experiment when order preservation was a criterion for success, a result that cannot easily be accounted for by the consolidation theory discussed earlier. We are now attempting experimentally to clarify further the roles of attention and consolidation in memory. A preliminary interpretation is that, with high arousal, subjects take in less information but pay more attention to it. This could give a variety of results for the short-term, depending on the ease of the task, readiness to guess, and so on, but in the long-term should always give better recall for high arousal because the consolidation process has a larger or more well-defined trace on which to operate.

Antagonistic Effects of Tryptamine and β-Phenylethylamine on the Behaviour of Rodents

ACCORDING to Brodie and Shore, the behaviour of higher animals depends on neurohumoral agents produced in the diencephalon. Catecholamines such as noradrenaline and dopamine are said to act as ergotropic agents, whereas serotonin is their antagonistic trophotropic factor[1,2]. The essential validity of these concepts has been confirmed many times[3,4]. There are, however, some discrepancies concerning the supposed stimulating (ergotropic) effects of catecholamines; some results confirm their alerting action, but others point to a depressing effect[5,6]. We found[7–11] that not only catecholamines, but also their amino-acid precursor L-dopa, suppress exploratory behaviour in mice, whereas amphetamine derivatives, as well as β-phenylethylamine and its amino-acid precursor phenylalanine, enhance it; there is a mutual antagonism between the two groups of substances. Serotonin too suppresses exploratory activity in mice and produces a Parkinson-like state in rats, similar to that produced by reserpine. β-Phenylethylamine antagonizes these effects of serotonin[12]. We concluded that β-phenylethylamine rather than catecholamines should be considered the ergotropic agent, while serotonin, as proposed by Brodie and Shore, is its antagonistic trophotropic factor. It seems to us that catecholamines may function differently in particular systems, but they do not seem to stimulate motor activity. Amphetamine and its derivatives may act by liberating β-phenylethylamine.

Table 1. EFFECT OF β-PHENYLETHYLAMINE DERIVATIVES ON RESERPINE AND TRYPTAMINE PARKINSON-LIKE SYMPTOMS IN THE RAT

Drug	Dose (mg/kg)	No. of animals	Animals with Parkinson-like symptoms Catatonia	Akinesia	Tremor	Rigidity
Reserpine	5	20	18 (90%)	19 (95%)	19 (95%)	18 (90%)
Reserpine + β-phenylethylamine	5 50	20	1* (5%)	1* (5%)	20 (100%)	2* (10%)
Reserpine + methylamphetamine	5 2	20	1* (5%)	1* (5%)	20 (100%)	1* (5%)
Tryptamine	80	20	10 (50%)	19 (95%)	19 (95%)	0
Tryptamine + β-phenylethylamine	80 50	20	2* (10%)	2* (10%)	20 (100%)	0
Tryptamine + methylamphetamine	80 2	20	1* (5%)	1* (5%)	20 (100%)	0

* Values statistically significant ($P < 0{\cdot}01 > 0{\cdot}001$).

Dewhurst reached similar conclusions[13–15], except that he included tryptamine among the stimulating agents, maintaining that phenolic amines such as catecholamines and serotonin are depressing, whereas non-phenolic amines such as β-phenylethylamine and tryptamine are stimulating. Nevertheless, according to our results, tryptamine affects the behaviour of mice and rats in a manner very similar to that of serotonin. β-Phenylethylamine is an antagonizing rather than a synergizing agent to the effects of tryptamine. We have measured effects on exploratory activity in mice, using an actophotometer[16], and we have produced a Parkinson-like state in rats. Twenty female hooded rats (180–280 g body weight) received each of the doses indicated in Table 1. Drugs were dissolved in distilled water and injected intraperitoneally, 1 ml./100 g body weight. β-Phenylethylamine derivatives were administered 2 h after reserpine and 30 min after tryptamine. Results were evaluated by an "all or none" reaction as follows. Catatonia was considered to be present when the rats, put on a table with their forelimbs placed on a platform 6 cm high, remained still for at least 1 min. Akinesia was found when the rats made no exploratory movements for 2 min at least. Rigidity was present when the rats allowed themselves to be dragged by the tail without making escape movements. Absence or presence of tremor was assessed visually. Because tryptamine does not produce rigidity, this was not tested in assays with this substance.

The degree of phenylethylamine antagonism was expressed as the percentage of rats which still had Parkinson-like symptoms. Statistical significance was assayed according to Bancroft[17].

In our other investigations groups of six male white mice (18–30 g) were put in individual cages, and injected intraperitoneally 30 and 15 min before locomotor activity was measured for 10 min in the actophotometer. Reserpine was always administered 24 h before test. Results are shown in Table 2.

Table 2. EFFECTS OF RESERPINE, TRYPTAMINE, AND β-PHENYLETHYLAMINE DERIVATIVES ON THE EXPLORATORY BEHAVIOUR OF MICE

First injection	(mg/kg)	Second injection	(mg/kg)	Actophotometer reading (mean ± *S.E.*)
Distilled water		Distilled water		65 ± 5
Tryptamine	80	Distilled water		8 ± 4*
Reserpine	2	Distilled water		7 ± 2*
Distilled water		Methylamphetamine	2	101 ± 8*
Distilled water		β-Phenylethylamine	80	90 ± 9
Tryptamine	80	Methylamphetamine	2	101 ± 14*
Tryptamine	80	β-Phenylethylamine	80	91 ± 14*
Reserpine	2	Methylamphetamine	2	174 ± 14*
Reserpine	2	β-Phenylethylamine	80	48 ± 8*

* Results statistically significant ($P < 0{\cdot}01 > 0{\cdot}001$).

Tables 1 and 2 show that reserpine as well as tryptamine produces hypokinesia in mice. The reserpine syndrome in rats consists of catatonia, akinesia, tremor and rigidity, whereas tryptamine only produces catatonia, akinesia and slight tremor. These symptons, with the exception of tremor, which is enhanced, are antagonized by β-phenylethylamine and methylamphetamine. It seems that tryptamine produces not stimulation, but depression-like phenomena, and that β-phenylethylamine acts as its antagonist. Tryptamine as well as β-phenylethylamine passes the blood–brain barrier[13,18] and so there can be no objection on this count. We cannot explain the differences between our results and those of Dewhurst; maybe they have resulted because we used different animal species (rodents rather than newly hatched chickens) or because of some other experimental details.

Effects of Sexual Activity on Beard Growth in Man

DURING the past two years I have had to spend periods of several weeks on a remote island in comparative isolation. In these conditions I noticed that my beard growth diminished, but the day before I was due to leave the island it increased again, to reach unusually high rates during the first day or two on the mainland. Intrigued by these initial observations, I have carried out a more detailed study and have come to the conclusion that the stimulus for increased beard growth is related to the resumption of sexual activity.

Beard growth was measured quantitatively by collecting and weighing the shavings from the head of a Philips Philishave razor after a single shave once every 24 h. Activity data were recorded on a 0–5 scale with respect to physical and mental exercise, nervousness, sleep, libido and intercourse.

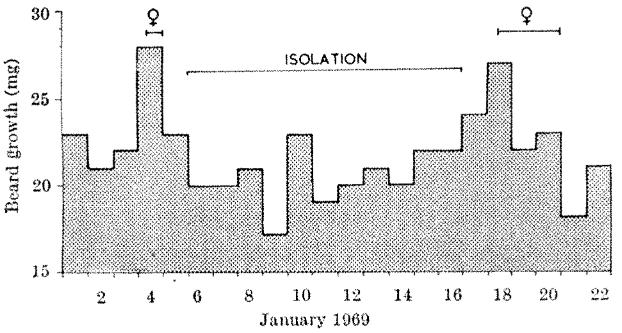

Fig. 1.

Fig. 1 illustrates the changes in beard growth during a short stay on the island. The day of return to the mainland and the initial resumption of sexual activity produced a most marked increase in beard growth, although growth subsequently declined fairly rapidly to baseline rates. If sexual activity was maintained for a week or more, then beard growth would still decline to normal rates within 4–6 days; resumption of sexual activity after only 2–3 days' abstinence was enough to restimulate beard growth. Even the presence of particular female company in the absence of intercourse, after a period of separation, usually caused an obvious increase in beard growth.

Perhaps the most interesting feature of these changes was the way the increase in beard growth anticipated the resumption of sexual relationships. The longer the period of abstinence, the more obvious was the anticipatory response. Fig. 2 shows the mean beard growth (± *S.D.*) for ten different 10 day recording periods in which sexual relationships were confined to the weekend. The cycle is unmistakable; the Friday peak comprises an anticipatory response during the day and the effect of intercourse; the increased beard growth falls off by Sunday, and by Monday it becomes smaller than on any other day of the week.

Although normal sexual relationships seem to have the most pronounced effects on beard growth, other factors are also of importance. Increasing the number of shaves in a day leads to a considerable apparent increase in beard growth, although decreasing the frequency of shaving did not necessarily have the opposite effect. Tension, anxiety, nervousness, excessive mental fatigue and alcohol consumption were all associated with increased beard growth, while excessive physical exercise and high ambient temperatures seemed to inhibit growth. The amount of sleep, type of food eaten and degree of libido were without effect.

Hamilton[1], in a comprehensive account of the effects of genetics, age and hormone levels on beard growth in man, stated that beard growth could be used as a bioassay for androgens because it was exclusively under testicular control. An attempt was therefore made to correlate the rate of beard growth with a known index of androgenic activity, the rate of sebum production by the sebaceous glands of facial skin[2]. The results are shown in Fig. 3; in general, there was good agreement between these two indices of androgenic activity.

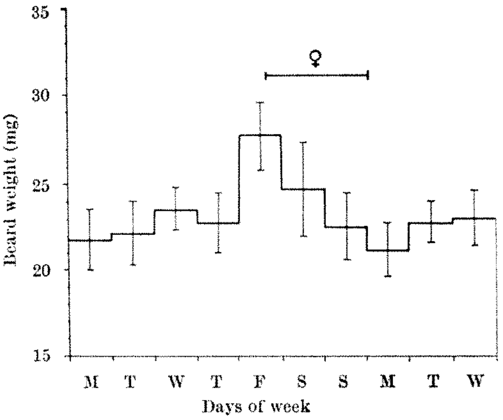

Fig. 2.

A variety of compounds, including testosterone, methyl testosterone, androsterone and cortisone (2 × 10 mg/day), were taken sub-lingually and beard growth changes measured. All the samples were coded and placebos were also included. The results show that all the androgens had a stimulatory effect on beard growth, androsterone producing the greatest increase. The changes were of the same order of magnitude as the increases associated with intercourse. Although the placebos were without effect, cortisone also stimulated beard growth, indicating that the beard may respond to other hormones.

In conclusion, it seems that beard growth in man is a much-neglected parameter of hormone activity that can readily be quantified. This study would suggest that the changes in beard growth in relation to everyday activities may reflect changes in the endocrine activity of the gonads or adrenal cortex. The fact that the beard shows a marked circadian rhythm of growth with a peak between 0800 and 1300 h, similar to the circadian rhythm of cortisol secretion, might suggest a functional interrelationship. Because the beard is a secondary sexual character developed under the influence of testosterone at puberty, however, it might be expected to retain a particular sensitivity to androgens. The pronounced effect of sexual intercourse on beard growth may therefore be caused by an increase in testosterone secretion, which is known to

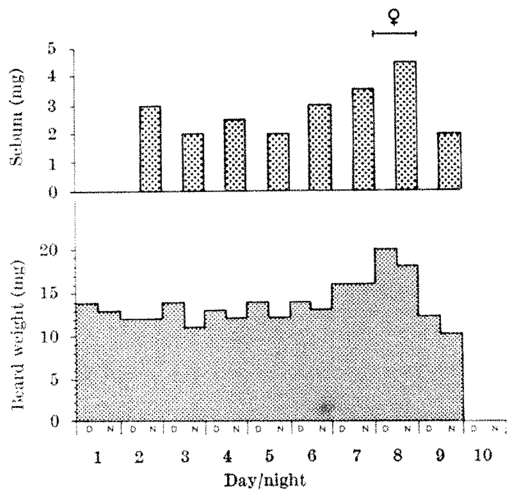

Fig. 3.

occur in response to coitus[3]; there is a 5–8 day cycle of testosterone secretion, and a rather similar 5–6 day cycle is sometimes apparent in beard growth.

Changes in beard growth may well indicate changes in androgen secretion in man, related to sexual behaviour, in that they suggest a release of androgen in anticipation of intercourse, a decline in androgen secretion with continued sexual activity, and hypersecretion of androgen in response to intercourse after prolonged sexual abstinence.

ANON

The identity of the author of this communication has been suppressed for reasons which may be self-evident, but the author, whose work has been vouched for by a colleague, has answered a number of questions raised by a referee.

Efficiency of Grass Carp (*Ctenopharyngodon idella* Val.) in controlling Submerged Water Weeds

THE Asiatic grass carp is a herbivorous fish which is being bred and extensively cultured for food in Russia and eastern Europe. In Britain where freshwater fish are seldom eaten, apart from eels and salmonids, grass carp are arousing interest because of the possibility of using them as a supplement, or in some situations as an alternative, to present methods of weed control—mechanical cutting or the use of herbicides[1]. The chief factors involved in the possible use of grass carp have been discussed[2,3], one of the most important being the density of fish needed to achieve a desired degree of control. We report here the work done on this topic in 1969.

Nine similar and adjacent ponds, each 0·025 hectares in size and about 0·8 m deep, were cleared of indigenous fish by using rotenone. The rather heterogeneous weed growth present was sampled by means of a grapnel at regular intervals along evenly spaced transects and recorded as relative frequencies, that is, the number of samples in which submerged weeds appeared as a percentage of the total number of samples per pond. Between forty-five and fifty-five samples were taken at each pond.

A stock of grass carp had been obtained in April 1968 from Hungary, where they were hatched in June 1967. After the first weed sampling the fish were introduced into six of the nine ponds on May 21 at the rates of 238, 241, 242, 484, 716 and 959 kg/hectare. The mean weight of individual fish was 168 g. Subsequent assessments of weed abundance were made in July, August and September.

In initial approximate order of abundance the submerged plants present were: *Myriophyllum verticillatum*, *Callitriche* sp., *Lemna trisulca*, *Potamogeton pectinatus*, *Zannichellia palustris* and *Ceratophyllum demersum*. The emergent and chiefly peripheral species were *Typha latifolia*, *Sparganium erectum* and *Alisma plantago-aquatica*. Although not all these species were present in each pond, when they occurred in ponds stocked with grass carp they were all grazed.

During the summer all species of weed in the ponds containing the fish decreased while the weed density in the three control ponds increased to a mean value of 110 per cent of the original. In the most heavily stocked pond the relative frequency of submerged weeds decreased from eighty-four in May to eighteen in August when plant roots—presumably pulled up by the fish—were seen floating on the water; it was clear too that the lowermost leaves of *T. latifolia* had been eaten. By September all traces of submerged plants had gone and all the *T. latifolia* leaves touching the water had been attacked by the fish. Grass carp are known to prefer some plants to others[4–7], and our results suggest that *Callitriche* sp. was preferred to *M. verticillatum*, but the initial variation in plant population between ponds and the method of assessment did not permit a reliable comparison.

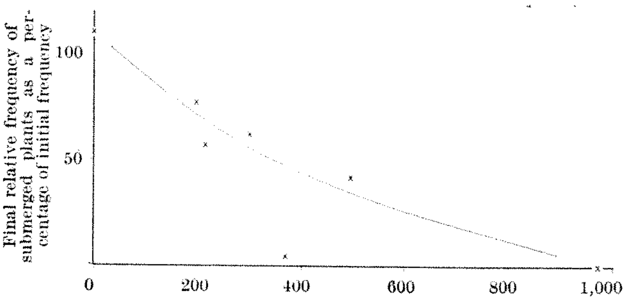

Fig. 1. Relation between the change in the relative frequency of submerged weeds from May to September and the grass carp stocking rate.

On September 22 and 23 the grass carp populations were estimated by a mark-recapture method and the fish were subsequently removed, weighed and measured. Mean survival was 61 per cent with a range of 34 to 97 per cent and the mean weight increment was 37·8 g (7·7–139 g).

From the initial stocking figures and the final numbers and weights of fish, a median-time biomass was estimated for each pond, assuming growth and mortality to have been linear and exponential respectively. The values obtained are plotted in Fig. 1 against the September relative frequencies of submerged weed expressed as a percentage of the May values and give a reasonably good curvilinear relation. The very low point in Fig. 1 is believed to be due to the fact that the initial plant population was low in this pond and consisted chiefly of *Callitriche* sp., which is not only readily eaten by grass carp but also tends to die back as the summer progresses as it did in the control ponds.

Thus in the summer of 1969 at a site where the daily mean water temperature was 15·8° with a range of 8·5° to 21·5° C, and with plants which are readily eaten, a stocking density giving a mid-season biomass of approximately 300 kg of 2 year old fish per hectare reduced plant growth to about 50 per cent of its potential. In the conditions of the experiment this mid-season biomass would, it is estimated, have required an initial stocking rate of 343 kg/hectare.

We thank the Deeping Fen, Spalding and Pinchbeck Internal Drainage Board and the Welland and Nene river authority for facilities for this work.

Absolute Pollen Diagram from the British Late-Glacial

BLELHAM BOG, a National Nature Reserve 1·2 km west of Windermere, overlies two small infilled kettleholes in gravels of the latest major glaciation. In the western kettlehole the succession of late-glacial sediments includes two organic layers (carbon content approximately 20 per cent of dry weight) respectively 5 cm and 40 cm thick, separated by a silt of low organic content (carbon about 6 per cent). Two radiocarbon dates from the lower organic layer, 12,380 BC ± 230 and 12,330 BC ± 230 (Q 758), and descriptions of stratigraphy, pollen analysis, diatoms and Cladoceran remains in the late-glacial sediments have been published[1-5].

A grant from the Royal Society to W. P. made it possible to obtain ten further dates from the profile, from the firm Isotopes, and so to determine the changes in annual pollen deposition per unit surface area of lake mud. Using the time scale based on the eleven closely spaced radiocarbon dates (Fig. 1) and pollen counts related to a measured volume of fresh sediment, it has been possible to prepare an absolute pollen diagram in the manner of Davis and Deevey at Rogers Lake[6]. The pollen counts per unit volume were carried out by a modification of the technique outlined by Benninghof[7] and described by Matthews[8] using an added suspension of exotic pollen grains. A full description of this modified technique will be published by A. P. B. with details of the statistical methods by which the confidence limits of the counts were calculated.

The ten additional dates confirm the very early date of the lower organic layer (Q 758) and provide a consistent pattern of three successive Late-Weichselian periods, each differentiated stratigraphically and characterized by a different accumulation rate. We recognize that the dates, like all radiocarbon dates from lake mud, are open to criticism because of possible incorporation of ^{14}C deficient carbon during the photosynthesis of aquatic plants, even though these sediments are non-calcareous. Fig. 1 shows how the time scale based on these dates assigns a length of about 500 years to the post-Alleröd period of severe soil erosion which produced minerogenic sediment at Blelham Bog; this agrees closely with the generally accepted length of this period, Younger Dryas[9]. The dates for the beginning and end of this period on the Blelham Bog time scale are between 300 and 500 years older than those usually given in recent reviews[9,10].

Fig. 2*a* shows the pollen zones into which the percentage pollen diagram can be divided, and the correlation of these with lithostratigraphic units. Fig. 2*b*, the absolute pollen diagram, is divided by the zone boundaries which are defined on the percentage pollen diagram.

Conclusions from study of the absolute pollen diagram must be: (i) Zone B*a*, defined by predominance of *Rumex* (mainly *acetosa* type) and grass pollen, represents a section of the profile of very low pollen deposition per year throughout. On the uncorrected time scale this section represents the period from just before 13,000 BC until about 11,000 BC. Within this section the lower organic layer must represent only a local environmental fluctuation within the former kettlehole pond, for it is not differentiated from the minerogenic deposits above and below it by any significant change in pollen input. The percentage increases in pollen of juniper and tree birch within the organic layer[1,4] "represent statistical artefacts rather than significant vegetational changes"[6]. The low values per unit area per year for tree birch and juniper grains indicate that these high pollen producers cannot have been contributing materially to the local pollen grain, so grains of these taxa in deposits of Zone B*a* must have been derived chiefly from distant transport.

(ii) Zone B*b*'s lower boundary corresponds to an increase, more than ten-fold, in the total input of pollen grains per year per unit area. The input of all taxa increases, but the rapidity of the absolute increase in juniper produces the high juniper percentages which define zone B*b*. Both the herbaceous taxa characteristic of Zone B*a* and tree birch pollen increase absolutely at the zone boundary B*a*/B*b*; the annual input of *Betula* grains increases through the deposits of Zone B*b* to reach maximum values in Zone B*c* above. At the zone boundary B*b*/B*c* a steep fall in the annual input of juniper begins. Input of the herbs, grasses, sedges, *Rumex* and *Thalictrum* increases by a mean factor of about 6 at the zone boundary B*a*/B*b*, and remains at about this level through Zones B*b* and B*c*. *Artemisia* has consistently higher absolute values in Zone B*b* than in B*a* or B*c*.

These facts can most easily be explained by the hypothesis that the zone boundary B*a*/B*b* represents a major change in pollen input, most probably the result of a rise in temperature. Herbaceous plants of all communities represented by the pollen spectra of Zone B*a*, on this theory, responded by increased flowering and pollen production. Juniper, hitherto stunted and sparsely flowering, responded immediately by the production of erect flowering branches, as suggested by Iversen[11]. The slow increase in pollen input from tree birches, beginning at the zone boundary B*a*/B*b*, implies a slower response to environmental change, explicable by the time-lag involved in migration of tree birches from distant sites. When birch trees reached the site, juniper would be shaded out, producing the steep fall in pollen input of juniper at the B*b*/B*c* boundary. Sustained input from grasses, sedges and *Rumex* through Zones B*b* and B*c* indicates that the spread of the woody plants did not materially reduce pollen input from herbaceous communities.

(iii) Zone B*c*, the *Betula* zone, represents ecological equilibrium during the full development of the interstadial. Within the next zone, B*d*, pollen input of *Betula* falls irregularly from its maximum in B*c*, and that of *Juniperus* increases. Irregular break-up of birchwoods with increased flowering of juniper would produce these results. The "forked" percentage curve for *Betula* resembles that found at many Danish sites[12] and used there to divide Zone II into *a*, *b* and *c*. A similarly forked

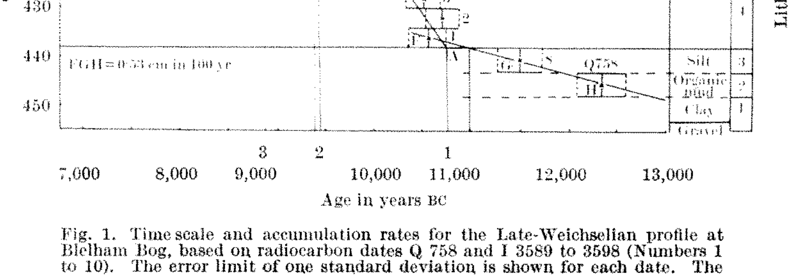

Fig. 1. Time scale and accumulation rates for the Late-Weichselian profile at Blelham Bog, based on radiocarbon dates Q 758 and I 3589 to 3598 (Numbers 1 to 10). The error limit of one standard deviation is shown for each date. The graph showing accumulation rate has been plotted as follows: DE and FGH represent sections where three dates fall on a straight line, and ABC represents the line of best fit calculated for samples 1 to 7 inclusive. The numbers 1, 2 and 3 on the lower axis show the positions on the time scale of the three major changes in lithostratigraphy.

curve for input of *Filipendula* pollen at Blelham Bog agrees with the interpretation of this as the result of a fluctuation in temperature.

(iv) At the zone boundary B*d*/B*e* total annual input and numbers of grains of *Betula* and *Juniperus* fall steeply, *Juniperus* to an absolute minimum for the profile. Increased input, first of *Rumex* (mainly *acetosa* type) and then of *Artemisia*, produces the successive maxima in the percentage diagram on which pollen zones B*e* and B*f* are defined. Pollen input is low, but higher than in the pre-interstadial period. The increased input of *Artemisia* represents a higher contribution from plants of disturbed soils than at any other time during the Late-Weichselian.

(v) Pollen zones B*g* and B*h* represent the transition to the basal *Betula* zone of the Flandrian.

Here is evidence for a single interstadial in a Late-Weichselian profile for which the radiocarbon dates go back to 12,380 BC ± 230. Pollen zone B*a* corresponds, in the predominance of non-woody taxa, to Zone I; pollen zones B*c* and B*d* together equate with the classical Alleröd or Zone II, in which tree birches dominate the pollen spectra; and pollen zones B*e* and B*f* together equate with the post-Alleröd recession, Zone III. The peculiar feature of the Blelham Bog profile is the evidence, in Zone B*b*, for a rapid climatic improvement before the opening of the classical Alleröd (as customarily defined by

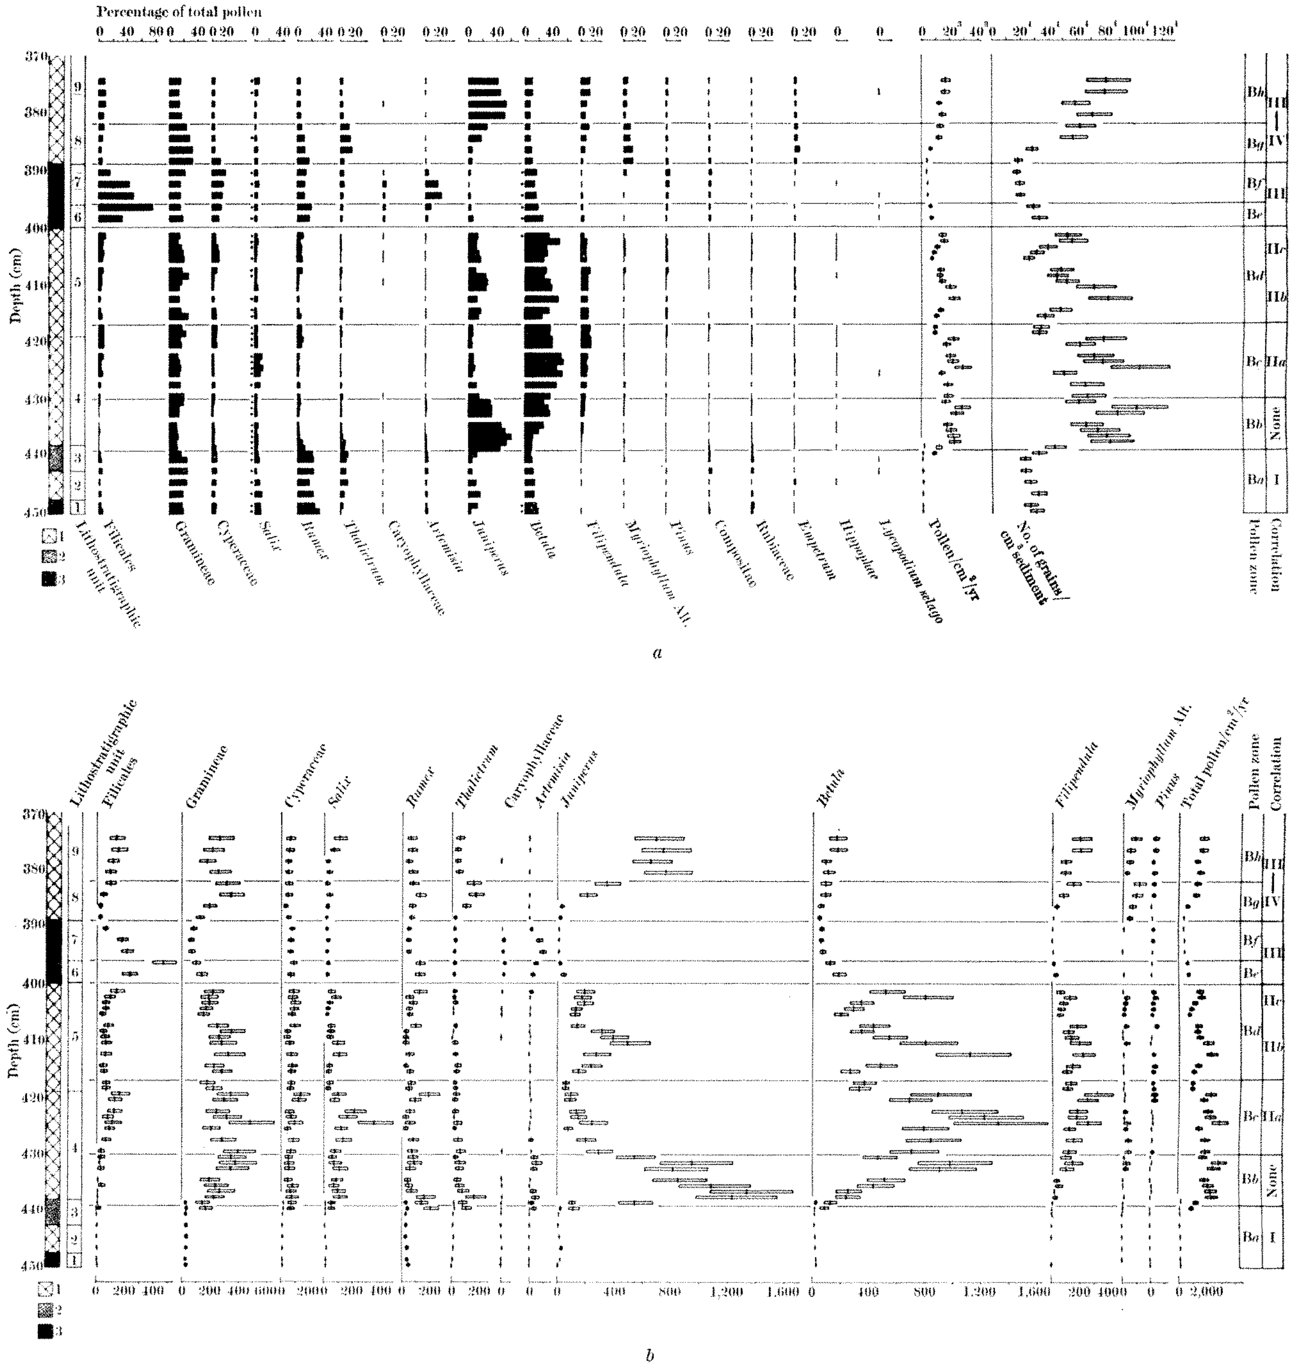

Fig. 2. Pollen diagrams from the 1968 profile from Blelham Bog. (*a*) Counts expressed as percentages of total pollen, together with plots of total numbers of grains, per square cm per year and per cm³, respectively. The pollen count for each sample was between 450 and 800 grains. The presence of *Betula nana* and of *Salix herbacea* is indicated by a cross on the left of the histogram for the genus. (*b*) Counts expressed as numbers of grains per cm² per year of the most important taxa. The plot for each value indicates the 90 per cent confidence interval for the counting error only. The count for each sample was 1,000 grains of fossil plus exotic pollen. Stratigraphic symbols: 1, organic mud; 2, silt of low organic content; 3, clay.

the rise in percentage frequency of tree birch pollen). This improvement, dated on our time scale to between 10,750 BC and 11,000 BC, is deduced from simultaneous changes in lithostratigraphy, in percentage pollen spectra and in pollen input per unit area per year. In none of these is there any evidence for recession between this amelioration and the tree birch period (Alleröd); on the contrary, the sequence can be interpreted as a continuous ecological succession. This reinforces the suggestion of Kirk and Godwin's dated pollen diagram from Loch Droma[14] that the onset of interstadial conditions began in western Britain early in the eleventh millennium BC, and that between this time and the height of the Alleröd interstadial there was no general climatic recession of sufficient amplitude to deflect the plant succession or to give rise to increased soil erosion. Our absolute pollen diagram provides evidence that the much earlier environmental fluctuation recorded in the stratigraphy of the Blelham Bog deposits was not accompanied by any significant change in pollen production by the local vegetation.

The sequence in this profile contrasts with that found at Danish sites such as Böllingsö[12,13], where a minor interstadial defined by the curve for tree birch pollen, Zone I*b* dated as 10,450 BC to 10,050 BC[9], is separated from the overlying Alleröd deposits by a minerogenic layer with little tree pollen, Zone I*c*. This indicates a regional difference between western Britain and Denmark in the lithostratigraphic sequence and in the pollen curves, which can most readily be explained as the result of a regional differentiation in Late-Weichselian climate.

Fossil Ice in Hawaii ?

PERENNIAL ice was found late in 1969 near the summit of Mauna Kea, a dormant volcano rising 4,200 m above the sea on the island of Hawaii, 19° 49′ N and 155° 28′ W. A part of the ice-lava mixture lies close to the rocky surfaces near the bases of the south walls of the Goodrich Cone and Summit Cone craters (Fig. 1). Seismic refraction measurements have indicated a minimum horizontal extent of ice of hundreds of metres, and a thickness of many decametres. This ice may be the remains of known Pleistocene glaciation[1]. It is thought to survive near the surface in present climatic conditions because radiation effects make certain areas of the craters colder.

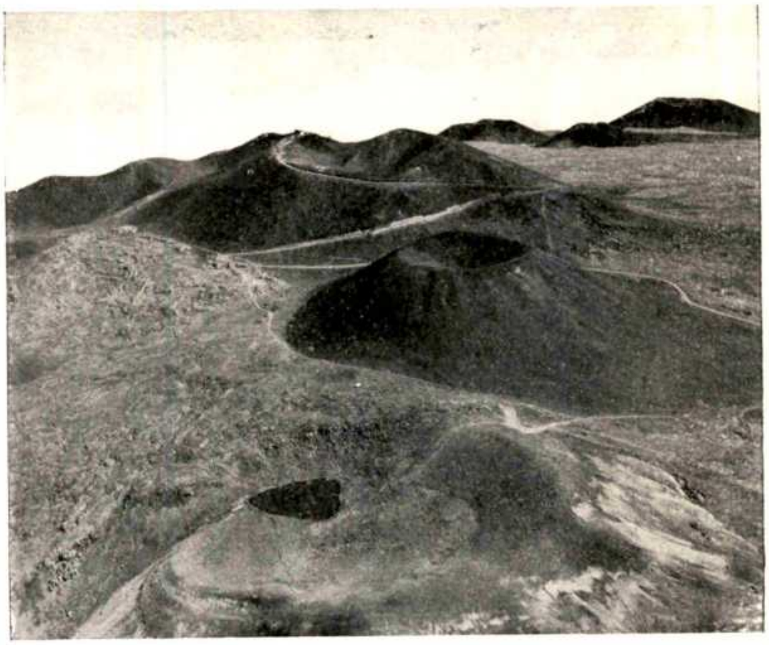

Fig. 1. Photograph of Mauna Kea summit looking north-north-east over Lake Waiau, which is in Waiau Cone crater, towards the Astrophysical Observatory of the University of Hawaii. The highest point, just to the right of the observatory, is immediately above the crater where the first old ice was found. Goodrich Cone crater, where more of the ice occurs, is to be seen between the lake and the summit. (Photograph by A. J. Abbott, Hawaii Institute of Geophysics.)

Carbon dating of Lake Waiau (Fig. 1) sediments[2] and temperature measurements in perched lake and ground waters[3], motivated by earlier geological and seismic exploration[1,4], led to the discovery of the ice. Brief examination at many locations revealed: (1) that the ice completely fills the interstices between the lava rocks and boulders; (2) the remains of insects imbedded in the ice; and (3) that the ice is clear, bubble-free, and tritium-free a few centimetres down.

Plans for further work concerning Mauna Kea include publication of seismic results, climatological studies in the craters, further seismic exploration, and drilling to collect deep ice samples. Evidence of climatic, biological and other conditions during Hawaii's remote past may be preserved in the ice.

Dr E. S. Deevey of Dalhousie University, Nova Scotia, Canada, helped at a critical stage in this study. Mr Theo Hufen of the Hawaii Institute of Geophysics made tritium measurements and Mr J. F. Campbell and Mr D. M. Hussong of the institute helped with the seismic work. The research was supported in part by the US Office of Naval Research.

Bivalve-growth Patterning as a Method for Seasonal Dating in Archaeology

ARCHAEOLOGICAL evidence is often found for the exploitation of marine resources. In New Zealand, one of the most widespread species exploited was the intertidal bivalve *Chione stutchburyi*, and its growth dynamics form the basis of the technique described here, the purpose of which is to determine at what time of the year shells were collected.

Following the approach of other workers, studies of living populations of *Chione* indicated that, in general, the bands or rings on the surface of the shells (macro-rings) were the result of winter growth recession[1-4]. Further, when cross-sections of the shells were photomicrographed (Fig. 1) two major types of banding (micro-rings or bands) were observed—fine black bands and relatively broad white bands. The latter sometimes contain faint dark lines, indicating two growth phases between each black band. In a sample of twelve modern shells the number of major black rings between the two major winter rings varied from 300 to 420 with a mean of 358, suggesting that the black bands may be formed daily.

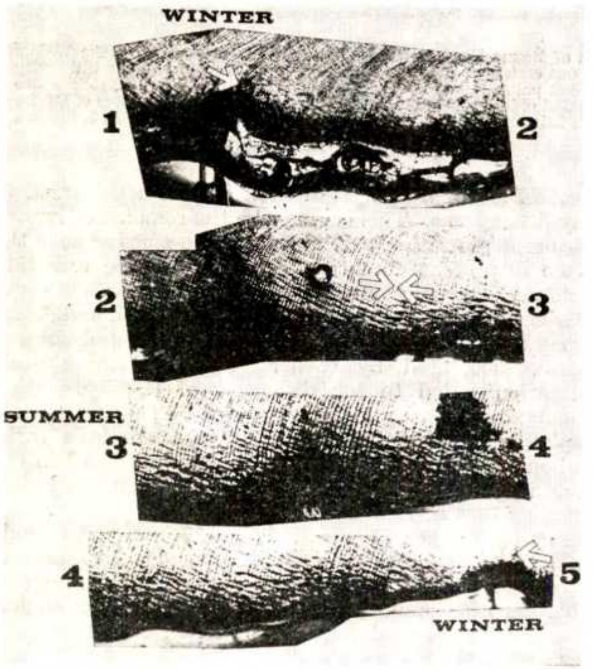

Fig. 1. Photomicrograph of a transverse section through the umbo of *Chione stutchburyi*. Daily micro bands are clearly discernible between the annual growth rings (macro bands). The latter are indicated in the photo by the vertical arrows. The horizontal arrows indicate the position of a pair of bidaily bands.

There is also considerable variation in the width of the bands throughout the year; they are very much wider in summer and spring.

An approximate estimate of the season of death of both modern and archaeological shell samples may be made, first by examining the variation in the thickness of the daily bands from the last macro-ring to the shell margin, and then by counting the number of daily growth bands from the last macro-ring to the shell margin. Provided that the approximate date when the macro-rings are formed is known, the date of death of individual shellfish may be estimated. For *Chione* this was determined by observing the growth dynamics of living populations over a period of twelve months.

A comparison between the known and estimated dates of death in twelve modern specimens (Table 1) suggested that an accuracy within a range of three months can be obtained.

Table 1. COMPARISON OF ESTIMATED DATES OF DEATH OF *Chione stutchburyi* WITH KNOWN DATES OF DEATH FROM THREE COLLECTING AREAS

Locality	Date of collection	Sample No.	Average No. of black bands from last winter rings to shell margin	Season of collection based on variations in the width of the bands
Area B Doctors Point	20/4/69	4	234 ± 20	Autumn
Area B Doctors Point	23/5/69	4	275 ± 20	Autumn
Tiwai Point	9/4/69	4	220 ± 15	Autumn

The method has been applied to shells from several coastal sites in New Zealand and the estimated seasonal dates, along with those obtained from other faunal data, are shown in Table 2.

Table 2. ESTIMATED DATES OF DEATH OF SHELLS FROM THREE ARCHAEOLOGICAL SITES IN SOUTHERN NEW ZEALAND COMPARED WITH SEASONAL DATES DEDUCED FROM OTHER EVIDENCE

Location of archaeological sites and stratigraphic position	Shell species considered	Average No. of black bands from last winter ring to shell margin	Estimated months during which shells were collected (by microscopic technique)	Estimated period of year when site was occupied from other faunal evidence
Tiwai Point TW PQ/40	*Chione stutchburyi*	110 ± 10	Dec–Feb	Oct–April
Tiwai Point P/30	,, ,,	90 ± 10	Nov–Jan	Oct–April
SP/1 TR B, sq 3, spit 1. Concentrated midden (SP = Southport)	,, ,,	146 ± 15	Dec–Mar	Nov–June
SP/1 TR C, sq 1. Concentrated midden	,, ,,	120 ± 15	Dec–Feb	Nov–June
SP/4 TR C and D, sq 2 and 3. Cockle	,, ,,	128 ± 25	Nov–Mar	Nov–June
SP/5 TR H, sq −5. Spit 2. Organic	,, ,,	101 ± 20	Dec–Feb	Nov–June
SP/5 TR E, sq, −7. Spit 2	,, ,,	103 ± 10	Dec–Feb	Nov–June
Wakapatu	*Protothaca crassicosta*	200 ± 20	Mar–April	Oct–April

Thus in New Zealand, at sites such as Tiwai Point and Wakapatu, the relatively thin midden deposits and presence of the bones of migratory birds suggest temporary occupation during the summer. In advancing a hypothesis that the sites were occupied at this time of the year for the exploitation of seasonal food sources, it must nevertheless be remembered that both fish and birds were dried and transported over fairly great distances during the protohistoric period in southern New Zealand. A means of checking this hypothesis is necessary. Although shells were also carried quite far during the protohistoric period in New Zealand, the number and weight of the shells that constitute the coastal middens in question rule out the possibility that they were transported to the sites from elsewhere. Shellfish were dried and stored during the protohistoric period[5], though there is no evidence that large quantities of the shells themselves were carried over any distance from the point of collection.

The implications of these results for the prehistorian are clear. The technique described provides not only a check but also a fairly refined estimate of the season at which the sites were occupied.

Book Reviews

MYTH-MAKER

The Raw and the Cooked

Introduction to a Science of Mythology I. By Claude Lévi-Strauss. Translated from the French by John and Doreen Weightman. Pp. 387. (Cape: London, April 1970.) 65*s*.

In a recent edition of *The Times Literary Supplement*, Professor Longuet-Higgins drew a comparison between chemistry and cooking as both being activities concerned with experiments and observations on real substances. While regarding cooking as an admirable occupation he will not accept it as a science—"The difference is that chemistry is not an isolated study—a law unto itself—but part of an intellectual edifice designed to express our understanding of the whole material universe". Claude Lévi-Strauss would disagree with Professor Longuet-Higgins on this point, for the very foundation of *The Raw and the Cooked* rests on the assumption that cooking, its categories, its operations and its transformations, are the culinary code part of an intellectual edifice through which can be expressed not simply an understanding of a whole material universe but a whole spiritual one as well.

The Raw and the Cooked is the English translation of *Le Cru et le Cuit* which, as the first of the *Mythologiques*, appeared in 1964, and has since been followed by two further volumes with a fourth one promised. For the reader new to this science of mythology it is difficult to provide an adequate summary of this work. It is a wide-ranging comparative study of myth which starts with the Bororo Indians of Central Brazil, is chiefly concerned with the myths of South America, but does not hesitate to draw supporting evidence from societies situated in any time or place. This is permissible because of the fundamental unity of the human mind, which is partly what the exercise is concerned to demonstrate.

The difficulty of dealing with this work in a brief review, and even perhaps the impossibility of it ever being submitted to truly critical assessment, has been assured by the author: ". . . this book on myths is itself a kind of myth. If it has any unity, that unity will appear only behind or beyond the text and, in the best hypothesis, will become a reality in the mind of the reader" (p. 6). When, in 1955, Lévi-Strauss declared that Freud's Oedipus complex was simply an up to date version of the myth and no less a myth, one might have thought that he was being disparaging about the founder of psychoanalysis by casting him in the role of myth-maker. We can now see, however, that Lévi-Strauss meant this as a compliment, but it does mean that the structural analysis of myth, like psychoanalysis, is above criticism except through further analysis of the same sort.

This situation is worsened because critical access through the empirical evidence is also prevented. Lévi-Strauss carefully covers himself against the criticisms of the specialists in the ethnographic evidence which he has used, and he has found support in a reviewer of the third volume of the *Mythologiques* who claims that to worry about the factual base on which the whole science of mythology is built is to misunderstand Lévi-Strauss. This can only mean that facts may as well be dispensed with entirely, and indeed the ease with which Lévi-Strauss manages to fit what would appear to be contradictory evidence into his schema gives additional support to such a suspicion. One of the difficulties about a method which proceeds on a dialectic of oppositions and transformations is that almost any evidence can be incorporated if one is imaginative enough to think of the opposition, or tenacious enough to find one in the myths of the world.

The translators, John and Doreen Weightman, have made an excellent job of a very difficult task, and if passages do not seem to make much sense to the reader, it is not the fault of the translators but simply a reflexion of an opaqueness in the original. Having said this, one must add that the translation does Lévi-Strauss a disservice; in 1955 he stated that myth belonged to a linguistic pole at the other extreme from poetry in so far as the latter could not be translated without distortion while myth retained its value through the worst translation. It seems to me that the act of translating *Le Cru et le Cuit* refutes this because in the process it has been demythized. Freed from the myth-maker's language, the words lose their sacredness and the arguments become more glaringly defective.

On the other hand, with some experience of South American ethnography, I have found many of the ideas in this volume and the later volumes of the *Mythologiques* very enlightening, and have been amazed by the ingenuity and fertility of a mind which can make such improbable but farsighted connexions. There is no doubt that this book will sell on the author's name (the publishers recognize this by placing the author's name in letters four times larger than the title), but who is going to read it and who is going to understand it before it takes its silent place on the shelf alongside *The Golden Bough*?

Peter Rivière

TOWN LIFE IN AFRICA

Social Networks in Urban Situations

Analyses of Personal Relationships in Central African Towns. Edited by J. Clyde Mitchell. Pp. x + 378. (Manchester University Press: Manchester. Published for the Institute for Social Research, University of Gambia. November 1969.) 55*s*.

"Each individual in a society", one of the contributors to this symposium tells us, "has social relationships with a large number of friends and acquaintances. All these relationships together constitute what has been called a personal network." Starting from some such simple definition, and adding a few additional concepts, Mrs Wheeldon and two of the other contributors, Dr Epstein and Mr Boswell, are able to provide relatively straightforward and illuminating analyses of several previously unconsidered aspects of social life among one Coloured and two African communities in three different Central African towns.

The remaining contributors are much more ambitious in their use of the network concept. To understand fully their papers, the reader must master a sizable technical vocabulary that includes such terms as anchorage, reachability, density, range, content, directedness, durability, intensity, frequency, star, zone, cluster, boundedness, finiteness, reticulum and span. He may also be expected to have or to acquire some familiarity with mathematical graph theory and its sociological applications. Assistance in this considerable task is offered by Professor Mitchell who, in a paper that often draws heavily on the literature of American social psychology, reviews the meaning of many of the concepts and suggests ways in which they may relate to and improve upon earlier modes of anthropological analysis. Further help comes from Professor Barnes, whose paper develops the morphological implications of a social network far beyond anything that even he can have expected from it when he first introduced it in 1954.

Sophisticated applications and additional refinements of some of the concepts are provided in Dr Kapferer's analysis of the course and consequences of a dispute among a small group of African industrial workers in Broken Hill, and in Mr Harris-Jones's paper on the political meaning and significance of the ties arising from common rural origin amongst Africans living in the town of Luanshya.

It is noticeable, though, that in spite of the often close collaboration between the contributors, they do not always use the same words in the same senses. Such discrepancies make me doubt the practical wisdom, whatever the theoretical attraction, of bringing so many new terms into a situation where already, as Barnes writes, "each analyst reads a different interpretation into the writings of his predecessors and introduces new refinements to suit his own particular problem". I would complain, too, about some of the many proffered diagrammatic aids to the understanding of often complex arguments. Apart from minor, but irritating, faults in proof-reading such as the omission of one arrow and the reversal of another in Figure 1 (a), there are several tables and figures which are not self-explanatory and which it is the author's, not the reader's, job to elucidate.

Some of the conclusions to which these lengthy and elaborate arguments lead seemed suspect to me. How, for example, can Barnes possibly maintain that "under tribal conditions the denseness of the network leaves no room, as it were, for the addition of those idiosyncratic relationships of friendship with strangers, or even of patron and client, that helps to fill in the relatively sparse urban network" ?

The statement is contrary to fact, and rests on a dichotomy that seems increasingly untenable. I might, also, be more willing to accept Mrs Wheeldon's contention that "the many disagreements which are characteristic of Coloured social organization are not an indication of social disintegration; they are rather an aspect of the integration of a society of this kind", if there were not increasingly ample evidence that such disagreements in many African societies of an apparently similar kind can and do lead to schism and even violence on a scale which might legitimately be called "disintegration".

Still, the book is clearly, in many ways, one of the most remarkable anthropological contributions to urban studies that has ever appeared in Britain. It is likely to have a revolutionary effect both on those who wish for new ways of organizing their research, and on those who are eager to carry anthropology far beyond any traditional conceptions of its scope and methods. It has, too, a good deal to offer to those who are merely interested in Central African societies. W. J. ARGYLE

BACK TO DARWIN

Genetic Load

Its Biological and Conceptual Aspects. By Bruce Wallace. (Concepts of Modern Biology Series.) Pp. xi+116. (Prentice-Hall: Englewood Cliffs NJ and Hemel Hempstead, February 1970.) 60*s*.

THERE is a strange notion, derived from mathematical theories of evolution, that populations of organisms are threatened by a "genetic load", sometimes called the "cost of evolution". This idea looks fair to be for twentieth century evolution what phlogiston was for chemistry in another day; Professor Wallace's strength is that he plainly believes in oxygen.

Darwin said that the overproduction of organisms caused much dying, and that evolution occurs because early death is more likely for some than others (that is, natural selection). The theory of the genetic load goes into reverse gear and asks "As natural selection requires so much dying (a genetic load), how is it that organisms can evolve, or for that matter maintain their genetic variability, without becoming extinct ?" Wallace has a simple answer.

"Discussions of genetic load have too often failed to recognize the ecological aspects of population dynamics." Within wide limits a population absorbs new causes of death by a slight reduction in size; as the genetic load increases or decreases, it "is either drawn from or returned to the general ecological load of which it is a part", for most of the offspring produced must die in any event. If half the offspring die from genetic causes, that does not result in a population of only half normal size. But "the genetic load must not exceed the reproductive ability of [the] species". To account for the variability of natural populations, we must allow first that much of natural selection is "soft" or density-dependent, occurring only at high densities (a return to the original Darwinian idea); second, that the optimal genotype, with whose fitness that of the population is compared, is vanishingly rare in natural populations, so that the usual load theorem is unrealistic.

For the human population the story is different (Muller's idea that Man's genetic load might threaten the growth of his population would be funny if the position wasn't so tragic): as the genetic load means human misery, there is no excuse for throwing radioactivity around.

This argument, presented with great clarity (at the expense, it must be said, of some realism, but then the facts, about *Tribolium* for instance, are just too complicated), makes the third part of the book required reading for all geneticists and ecologists. An important question remains—how do populations avoid accumulating genetic variation that is maintained by "hard", that is, density-independent, selection ? Perhaps many don't; after all, there are more species extinct than extant.

The first two sections review the evidence for the genetic diversity of natural populations of fruitflies and men, and discuss some of the better known mathematics about the genetic load. Written with that transparent simplicity which is the mark of the assured master, they make an excellent introduction to these aspects of population genetics; any undergraduate who finds this mathematical treatment too much should not be reading biology.

The book is well produced, mercifully free of acres of Zipatone, and expensive. JOHN R. G. TURNER

ACCENT ON MAN

Évolution des Vertébrés

De Leur Origine a l'Homme. By Georges Vandebroek. Pp. xx+583. (Masson: Paris, 1969.) 120 francs.

As its title states, the aim of this book is to describe those parts of the pattern of animal evolution which are concerned with the line which leads from the higher metazoans to man. The existence of other lines and patterns of evolution is noted in the appropriate places, so putting the line to man in its context, but they are not dealt with in comparable detail. Professor Vandebroek, of the University of Louvain, concentrates on the points at which the line to man diverged from these other lines, because it was at these points that the various characteristics of man (vertebrate, tetrapod, amniote and so forth) were established. These matters are dealt with in a series of six chapters on the origins of the higher Metazoa, of the chordates, of the tetrapods (with special emphasis on the structure of the skull), of the mammals and of the eutherians (especially the primates). In each case, the evolutionary history of the parent group is described first, to form a basis for a more detailed discussion of the origin of the next, higher, group. The last three chapters are concerned with the mechanism of evolution and the concepts of species and of race, with the details of the origin of man himself, and with the present-day races and anthropological types.

These problems have interested Vandebroek for many years, and he has developed his own ideas on several matters. For example, he believes that Van Beneden's theory of the homology of the coelomic sacs of vertebrates with the mesenteric recesses of cerianthid coelenterates has been unfairly dismissed by modern workers. Vandebroek discusses this problem at length, with details of his own work, and concludes that Van Beneden was correct. Studies on gastrulation and the closure of the blastopore have further convinced him that the chordates are not related to the echinoderms and enteropneusts, but are more closely allied to the protostomes. This view in turn leads him to make comparisons between the circulatory and excretory systems of chordates and annelids based on the belief that they are basically homologous. Such views are highly controversial, and it is unfortunate that they have first been published in a book of this kind, rather than being first exposed to the winds of criticism and discussion by publication in a scientific journal. Vandebroek also believes that the monotremes are descended from the Permian dicynodont reptiles. Finally, he has elaborated a new theory on the homologies and evolution of the molar cusps in mammals, together with a complete new terminology for these cusps. This theory is thoroughly presented in his book, with the aid of a large number of excellent figures and photographs of the molar teeth of mammals. Published in 1961, his theory has not so far received any measure of acceptance from other workers in this field.

It is clear that Vandebroek's book is not suitable for the newcomer to this field of enquiry, who requires an explanation of the generally accepted view on these matters which he can then elaborate by reference to other textbooks. It will instead be of interest to the proponents of the "generally accepted view" who may wish to test it against the theories proposed by Vandebroek and, in the process, criticize his theories in their turn.

The book is extremely well produced, with many new and excellent figures and photographs. In contrast, the reader who wishes to consult the original papers which have influenced Vandebroek's thinking will unfortunately find, by way of a bibliography, merely a list of forty-six general textbooks. BARRY COX

DEVELOPMENT OF MALIGNANCY

The Cancer Problem

A Critical Analysis and Modern Synthesis. By Armin C. Braun. Pp. ix + 209. (Columbia University Press: New York and London, February 1970.) \$8.50; 76*s*.

IN cancer research, it seems that a disproportionate amount of attention has been given to the growth of malignant cells *per se*, compared with normal cells, and tissues. This very good book forces one to put malignancy in a much more meaningful perspective within the framework of cell and developmental biology. The central thesis is that the tumour problem is what controls the growth of normal cells and where this control breaks down in neoplasia. Metastasis and invasiveness are regarded as much less important. In approaching this problem, the author takes essentially an epigenetic view of cancer, arguing for the equivalence of the malignant state with that of a differentiated state: whatever enables cells to acquire heritable changes during development is essentially the same as the development of malignancy.

The books starts by lucidly reviewing the basic biological concepts that underlie approaches to the tumour problem, including a consideration of viruses, genetic influences and the essence of biochemical hypotheses. He gives very little attention to carcinogenic agents or X-rays because, "while they are important for initiation of tumour they play no part in the continued abnormal growth of the tumour cells". He then goes on to consider the regulation of cell division and the capacity of autonomous growth. This leads him to the nature of heritable cellular changes, and whether somatic mutation is an essential prerequisite. He concludes from consideration of viral transformation and the nature of differentiation that ". . . we have in the concept of active and inactive gene states within a constant cellular genome a very real and, above all, an experimentally testable alternative to the concept of somatic cell mutation as an explanation for the heritable cellular change that underlies the tumorous state generally". He also argues that there is evidence that the malignant state may be a potentially reversible event. This brief summary does not do justice to the large amount of information from a variety of systems, including plants that he so draws upon and describes.

In considering the normal and abnormal growth of cells, and in regarding the essential abnormality of tumour cells as their continued or autonomous growth, the author repeatedly expresses the view that, for a cell, the changes leading to cell division involve a radical reorientation in biosynthetic metabolism. This is based on the idea that for cell division much of the cell's economy must be directed towards the synthesis of mitotic spindle proteins, which he suggests may comprise up to 30 per cent of the cell's total protein, and is almost certainly wrong. Current estimates of the amount of microtubule protein in the spindle put it no higher than 0·2 per cent of the total protein. While this does not at all invalidate the main lines of argument in the book, it highlights its weakness: in attempting to interpret cancer within the framework of the control of cell division and differentiation of normal tissues, it is a bit like explaining the unknown in terms of the unknown. It is not, for example, just that our current ignorance of the control of cell division is profound, but also at the conceptual level the discussion of the problem is still confused. We do not have a clear image of how we should think of the intracellular control of cell division which is the paradigm for coordination within the cell. Mitotic operons provide a useful shorthand for concealing our ignorance when considering intercellular mechanisms, involving, for example, chalones, but even here our ignorance is striking. The situation *vis-à-vis* differentiation is not much better and the author is unfortunately too uncritical of the old concepts of embryonic organizers, fields and a plethora of inducing substance. I think I could make a strong case that organizer-inductor ideas were a conceptual error with near disastrous consequences for developmental biology.

The great value of this book lies in bringing together critically, clearly and briefly, within the current framework of cell biology, some of the essential features of the cancer problem. Its weakness is that the organizational problems of cell growth and development in terms of cell and molecular biology still elude us. But it gives hopes that this will not be for long. LEWIS WOLPERT

PERSONAL ENERGY

Energy and the Mitochondrion

By David E. Green and Harold Baum. Pp. xii + 205. (Academic Press: London and New York, January 1970.) 79*s*.

IT is difficult to disparage a book by an eminent researcher, but in all humility I feel I must take an exception to this misleading tome.

If one wishes to know how Professor Green currently views the field of mitochondrial and membrane research and of oxidative phosphorylation, this is the book to read. This is substantiated by the fact that two thirds of all the "special articles" references are from his laboratory, and by the preface stating that "we have restricted our presentation to the point of view to which we have been led by our experimental findings". The authors further state that "Notions and concepts that we believe no longer have validity have been passed over in silence"—in this brief sentence a large base of information is thus conveniently jettisoned.

To find out how Green and Baum interpret the universality of membrane conformational changes one needs only to consult the front cover and a figure (p. 58) which explain the phenomena of "nonenergized", "energized" and "energized twisted" states as the conformational cycle of the tripartite repeating unit—this latter entity is considered the key to all membrane phenomena. The electron micrographs of isolated mitochondria showing the various conformational states are recognized facts, but the intricate diagrams derived from these, which form the basis of this book, should, in my opinion, be considered very, very tentative interpretations and definitely not "a logical, integrated interpretation of the mitochondria as an operational and transducing unit". This is, in fact, one view of an overall system which may represent primary, secondary or possibly even artefactual phenomena.

In the last chapter, the authors try to extend their thesis to other energy transducing systems, ranging from pinocytosis to photosynthesis and including vision and muscular contraction. While I do not doubt the universality of some membrane conformation changes, this attempt at universality is stretching things a bit far. For example, the author's claim of a role for the tripartite repeating units in photosynthetic electron transport and phosphorylation is tenuous in the extreme—the evidence is hotly contested, and the inclusion in the book of unpublished work from Green's laboratory does not help matters. The electron flow schemes presented are also of dubious validity. Similar criticisms can be made for deductions on the process of visual excitation and amplification in rod outer and inner segments of the eye.

A concluding postscript chapter purports to lead "to a great simplification of the configurational picture" by now postulating four possible configurational states in all mitochondria. The evidence is derived from six unpublished papers, which is asking much, except from those already convinced.

An appendix has a very useful compilation of many formulae of compounds of interest to workers in the field of mitochondrial research.

I do not feel that this highly personalized book can be recommended for general students in biological fields (as is claimed on the flyleaf), but it may be of interest to specialists in the field who wish to follow the current lines of thoughts and research in the authors' laboratory.

D. O. Hall

STEROIDS AFTER NINE YEARS

Steroid Biochemistry

By Erich Heftmann. Pp. xiii + 220. Academic Press: New York and London, December 1969.) 89*s*.

In 1960, Heftmann and Mosettig wrote *Steroid Biochemistry* as an introductory text for plant and animal biochemists and physiologists, endocrinologists, pharmacologists and clinicians. The enormous increase in knowledge of steroids has rendered this book out of date, and Dr Heftmann has undertaken the daunting task of rewriting it in 26 pages less than the original. Organic chemistry has been kept to a minimum and only occasional use of jargon (hydride shifts) will upset the uninitiated. An attractive feature of the book is the wonderful panoramic view which it gives of steroid biochemistry. In some medical circles steroids mean little more than the adrenocortical steroids and their synthetic analogues. Here we are introduced to the rare and exotic steroids, without known function, which are found in plants and lower forms of animal life. It will come as a surprise to many that some of the well known mammalian steroid hormones are produced and metabolized in plants. There are fascinating references to the secretion of testosterone by water beetles, which have been used as aphrodisiacs in folk medicine, and steroid cardiac poisons in primitive trials by ordeal. Steroid analogues, drugs and inhibitors, which have found use in academic and clinical work, are mentioned with their structural formulae.

The author naturally does not attempt to refer directly to the original vast literature. He recommends the use of the index (16 pages), which correlates text pages, structural formulae and references in a bibliography of 692 books and reviews. The bibliography contains references to items in Russian, middle European and Scandinavian languages with titles translated. One wonders if the author has personal knowledge of the content of such articles and thus of their worthiness. This form of reference is perhaps the best one can expect in a small book, but it is often frustrating to be unable to trace the source of some statements. One would, for instance, like to check the reputed reduction of deoxycorticosterone to pregnanediol in man, and wonders if indeed it is not misleading even to mention this when so little space can be given to description of metabolism. Similarly, it would seem unwise to mention the alleged occurrence of equilin in an adrenal tumour without qualifying reference to evidence of identification. Predictably, there is no space for the description of experimental results which led to important discoveries.

The book is perhaps weakest in the sections dealing with endocrinology of steroids. One looks in vain for mention of recent work on the action of 5α-dihydrotestosterone. The description of the action of androgens in the foetus and neonate is not clear; nor is the reference to enzyme induction by androgens. One would prefer some reference to chemical and physical methods of measuring steroids rather than bioassays. The concentration of plasma oestrogens of less than 1 mg per 100 ml. is surely a printing error.

These criticisms are admittedly of rather a carping nature—one enjoys reading the book so much. The bibliography and the numerous structural formulae will undoubtedly prove most useful.

J. K. Grant

MOLECULAR CYTOLOGY

Handbook of Molecular Cytology

Edited by A. Lima-de-Faria. (North-Holland Research Monographs Frontiers of Biology, Vol. 15.) Pp. xv + 1508. (North-Holland: Amsterdam and London, 1969.) 560*s*.

The handbooks published by the Chemical Rubber Company are invaluable reference works; that the *Handbook of Chemistry and Physics* is now in its fiftieth edition and has seven stable mates speaks for itself. Unfortunately, anybody anticipating that North-Holland's *Handbook of Molecular Cytology* might resemble and be as useful as the CRC handbooks is in for a great disappointment. To be sure, this so-called handbook is large and expensive, but there the parallel with the CRC's publications ends. The *Handbook of Molecular Cytology* is nothing more than yet another collection of inevitably outdated review articles. It resembles nothing so closely as a bumper edition of *International Reviews of Cytology* or a one volume condensation of Brachet and Mirsky's *The Cell*.

This book is the fifteenth volume in the publishers' series "Frontiers of Biology" but differs from its predecessors in not being devoted to a restricted topic; it attempts to cover the whole of modern cytology and suffers as a consequence. Lima-de-Faria has gathered together a group of contributors which is distinguished enough, but for the most part all too familiar, with the result that the overriding impression the reader gets is of having seen the book's contents before elsewhere.

The section on chromosome organization, for example, begins with an article by Ris; Britten, McCarthy and Walker and his colleagues all have their say on satellite DNAs and the evolution of DNA base sequences; Bernhard writes on the ultrastructure of cancer cells, Callan on lampbrush chromosomes, Afzelius on cilia and flagella, Bennett on the cell surface, Robertson on the structure of membranes, and so on through the list of fifty-three contributors. The organization of the book is equally familiar. It starts with a section on the evolution of DNA and then progresses first to the organization of viral, bacterial and eukaryotic chromosomes, followed by the structure and bichemistry of the interphase and dividing nucleus, and ends up with the cavalcade of the cell organelles. I admit the volume is not entirely without surprises. The editor deserves to be congratulated, for example, for deciding to include articles on abnormalities of sex chromosomes and autosomal chromosomes, and for persuading Hamerton and Taylor, both from the Paediatric Unit at Guy's Hospital, to write them.

Books of this sort are always out of date before they are published; in this case, as far as I can see, the most recent references date from early 1968. And inevitably it is incomplete; somatic cell genetics, tumour virology and the work stemming from Watkins and Harris's discovery of virus mediated cell fusion are all topics one might expect to find discussed but they are barely mentioned.

The blurb talks of the handbook being the result of "the pressing need for a deeper understanding of the molecular interactions within cells" and of our being close to the threshold of some great synthesis that will provide an all-embracing view of the cell. The need for a deeper understanding of cells is obvious, but I doubt if this book will help much in bringing it about. Of course it contains many useful pieces of information but they are far from being in that particularly accessible form one expects of something parading as a handbook. Accessibility of information is precisely what has made the Chemical Rubber Handbooks so successful and useful. The *Handbook of Molecular Cytology* is not in the same category in spite of its title, and purchasers, even libraries, have a right to expect a great deal more than this tome offers if they are being charged £28.

JOHN TOOZE

NUCLEAR REACTIONS

Nuclear Reactions

By I. E. McCarthy. (The Commonwealth and International Library of Science, Technology, Engineering and Liberal Studies: Selected Readings in Physics.) Pp. viii + 327. (Pergamon: Oxford, London and New York, February 1970.) 45*s* ($7) boards; 35*s* ($5.50) flexi-cover.

THIS book is designed to introduce the theory of nuclear reactions to undergraduate students after a first course in quantum mechanics. The first part of the book contains a 100-page review of the theory of scattering and reactions, and is followed in the second part by a selection of original papers published between 1929 and 1965.

The introductory review covers the elements of scattering theory, the theory of the compound nucleus, the optical model, a discussion of nuclear structure and nuclear forces, and a discussion of direct reactions. The wide range of subjects and the condensed form in which they are described seem to make this section far too difficult for undergraduates. For example, the basic scattering theory, including the definitions of differential cross-section, partial wave expansion, resonance and the like, is presented without any diagrams at all, the physical significance of the asymptotic form of the wave-function is not discussed, and such terms as phase shift and channel radius are not explained. Later on, the description of compound nucleus theory is much more advanced than that usually given in undergraduate texts, and the discussion of nuclear structure includes the Bethe–Goldstone equation and the non-local K-matrix. It is doubtful whether this part of the book would be of any value to postgraduates, because those who are specializing in nuclear reactions would need a more detailed treatment of the subject and those who are reading for general interest would find the explanation of the physics rather inadequate.

The choice of original papers by Rutherford, Mott, Bohr and Serber seems ver appropriate, but the other papers chosen are much too demanding for undergraduates. While one can agree with the publisher's contention that undergraduates should not only learn from textbooks but should make acquaintance with the original literature, it will be cheaper and more profitable in this case to send the students to the library.

DAPHNE F. JACKSON

BUBBLE CHAMBERS

Cloud and Bubble Chambers

By C. Henderson. (Methuen's Monographs on Physical Subjects.) Pp. vii + 118 + 4 plates. (Methuen: London, January 1970.) 38*s*.

THE title of this book is not altogether appropriate: it is largely about bubble chambers, their application to accelerator physics and the processing and analysis of bubble chamber photographs. References to cloud chambers are not in comparable detail, are uneven and are on the whole slanted to their possible application in the same area: the discussion of cloud chambers provides no guidance at all to the sort of problems recently set by possible "quark" tracks from Sydney! The author is probably not as at home in the cloud chamber literature as in that of bubble chambers: for example, diffusion chambers of the Langsdorf type were first described in 1936, not 1939. If, as is probably intended, the cloud chamber material is provided for purposes of comparison of the nucleation process and principally as a background to bubble chamber technology, it would have been valuable to give also comparable data and discussion on the scope and usefulness of nuclear emulsions and the problems of track measurements in them, and perhaps a brief if wider survey of the whole field of application of "visual track" detectors of all kinds.

Subject to these reservations, which are really substantial only as regards the title, this is an excellent book which provides a concise, well written and readable background to the technology of bubble chambers used with large particle accelerators. It brings out clearly the problems of construction of the chambers themselves and of expansion systems, and the varying conditions and purposes for which different liquid fillings are suitable. The differences in bubble development in various liquids are treated admirably, and for the non-expert reader the very different optical problems in hydrogen and in heavy liquid chambers, and some of the elegant solutions of these problems, are some of the unexpected features which emphasize the practical approach in a very well balanced monograph.

The book gains from exceptionally well chosen and reproduced photographs, which are set out with excellent descriptive material. It should appeal to a very wide range of readers.

J. G. WILSON

ANALYSIS WITH ENZYMES

Enzymatic Methods of Analysis

By George G. Guilbault. (International Series of Monographs in Analytical Chemistry, Vol. 34.) Pp. xv + 347. (Pergamon: Oxford, London and New York, January 1970.) 75*s*; $10.

THIS book, which contains a relatively brief survey of some aspects of the use of enzymes in analytical chemistry, manages to convey a large amount of misinformation. The first chapter deals principally with enzyme kinetics, but only deals with single-substrate kinetics and makes no mention of enzymes which do not obey simple hyperbolic kinetics. Inhibition is, justifiably, divided into reversible and irreversible types, but the example of irreversible inhibition given is non-competitive inhibition, and the reader is told that: "In reversible inhibition, the enzyme can recover its activity when the inhibitor is removed; in the case of an irreversible inhibitor it does not." Later on in the book there is a figure implying that while an irreversible inhibitor will yield complete inhibition of an enzyme if a sufficient amount is added, a reversible inhibitor will never cause complete inhibition. We are also told that the international unit of enzyme activity is measured at 25°, although the temperature for such determinations has been fixed at 30° since 1964.

It would take too much space to give a complete list of the errors and misleading statements contained in this book, and it may be that the publishers could consider offering a prize for the reader who can spot the greatest number of errors. A few examples taken from other chapters in the book should, however, give an idea of the troubles. The chapter on the determination of substrates tells the reader how to determine DL-succinic acid, and advises the use of malate dehydrogenase for the determination of adipic, DL-citric and D-tartaric acids, although this same chapter contains a table indicating that none of these three acids are substrates for malate dehydrogenase. This table illustrates the remarkably low specificity of the commercial preparation of malate dehydrogenase used by the author, but no mention is made of the considerably higher specificity of highly purified preparations of this enzyme.

This book contains brief discussions of some of the less common methods of enzyme assays and gives enthusiastic accounts of some of the more devious coupling methods that can be used to increase the sensitivity of enzyme assays, but, because of the numerous errors, it represents a potential hazard to any unsuspecting student hoping to learn about enzymes and their uses. K. F. TIPTON

Obituaries

Professor H. H. Read

HERBERT HAROLD READ, FRS, died on March 29 at Whitstable, Kent, not far from the farm where he was born in 1889. Trained in geology under Watts at Imperial College, Read joined the Geological Survey of Great Britain in 1914 and served in Scotland for seventeen years interrupted only by three years of war service. In 1917, Read married Edith Browning who, with their only daughter, survives him. His Geological Survey work resulted in accounts of the layered basic intrusions in north-east Scotland, in extensive descriptions of migmatite complexes in the Northern Highlands and in Shetland, in substantial contributions to Dalradian stratigraphy and in the recognition for the first time of several important phenomena connected with metamorphism.

In 1931 Read succeeded P. G. H. Boswell in the chair of geology at Liverpool and subsequently followed Boswell once more to the chair of geology at Imperial College in 1939. In the same year Read was elected a Fellow of the Royal Society and in September was to preside over Section C of the British Association, though his address on metamorphism and igneous action was never delivered because of the outbreak of war. Publication of this address and of seven others which followed over the next fifteen years, including those given as president of the Geologists' Association (1942–44) and of the Geological Society of London (1947–49), established his international reputation. It is not easy to summarize the content of these addresses; leaving details aside, Read might be said to have attained two objectives. He set out to show how granitic rocks are distributed through the crust, paying particular attention to the role of granites in migmatite complexes, and to demonstrate that the non-fossiliferous crystalline rocks preserved a record of their geological history, which could be incorporated in the stratigraphical record already established through the study of sediments.

Read presided over the International Geological Congress held in London in 1948. In the same year he began his most extensive single investigation when, in collaboration with Professor R. M. Shackleton and Professor W. S. Pitcher and other colleagues, he started a survey, now successfully completed, of the crystalline rocks of Donegal, the results of which are set out in numerous papers. His researches led to his election to the National Academies of Belgium, France, Ireland and Norway, to honorary membership of many geological societies, and to the award of the Geological Society's Wollaston Medal and in 1963 of a Royal Medal from the Royal Society.

Read wrote with facility and was a masterly lecturer. As well as his four Geological Survey memoirs he wrote either alone or in collaboration with Janet Watson, five books and had a sixth in an advanced stage of preparation at the time of his death. In a review published in 1949 (*Geogr. J.*, **114**, 214), W. J. Arkell described Read's *Geology: An Introduction to Earth History* as a work of genius. This book epitomizes Read's ability to write clearly, attractively, often light-heartedly, and yet to convey a sense of awe. The final words of Arkell's review with his quotation from Read may be left to speak for themselves: "If by the time he reaches the last page the reader cannot enter into the spirit of the peroration: 'The geologist, standing on the earth as upon a footstool, looks at the past with wonder and turns to the future with hope', it will not be through the fault of the author".

Correspondence

Rhythm of Rabbit Teeth Cells

SIR,—Discussing the findings of Dr H. P. Rush (*Nature*, **226**, 406; 1970) that DNA synthesis in the slime mould *Physarum polycephalum* occurs immediately after mitosis and without an intervening G_1 period in the cell cycle, your correspondent suggests that most of the available data of this kind relate either to artificial situations, to slime moulds or to simple unicellular forms such as amoebae.

This is not entirely the case, however. In the proceedings of a symposium on naval medicine held at the Royal Society of Medicine in 1965 I reported that in rabbits the pre-ameloblasts (specialized cells concerned with laying down enamel matrix on the continuously growing teeth) have a cell cycle occupying between 19 and 20 h which was summarized in the following terms:

$$\begin{aligned} G_2+M+G_1 &< 10\text{ h} \\ G_2+M &> 9\text{ h} \end{aligned}$$

In other words, the duration of G_1 is very short, and synthesis must begin almost immediately after mitosis is complete[1].

Yours faithfully,

WILL STARKEY

MRC Dental Unit,
The Dental School,
Lower Maudlin Street,
Bristol BS1 2LY.

Reprint Request Reflexes

SIR,—When you accepted my letter (*Nature*, February 14, 1970) you asked me to let you know the result. Especially as you published a similar letter adjacent to mine, I suspect that I may be taking part in your experiment, which I do most willingly! My experiment was of the "try it and see" variety. The interim result, for the first period of nearly two months, is as follows.

The most gratifying result to me was receiving a number of appreciative letters from colleagues. So far, there have been twenty-one request cards from USA and Canada and twenty-one from other countries. The number from USA and Canada might well have been higher but for the gratuitous republication of our letters in the advertising paper *Dateline in Science* of March 6, which I suppose is widely distributed among pharmacologists and others with an interest in prostaglandins. In any case, Letters to the Editor may possibly attract fewer requests than main articles.

In the meantime, requests for the original article continue to come in and must now number more than a thousand. All are from biologists although the article was written for non-biologists. It seems that I much underestimated its popularity, even if one allows that the number of spurious requests was much greater than the forty-two suggested by the "experiment" so far. Even this number is big enough to make me think I should add at the end of my next paper "Reprint requests by personal letter will be met while supplies last". The alternative would be to ignore the lot, except for those from places where the journal might be unavailable.

Yours sincerely,

V. R. PICKLES

University College,
Cardiff.

SIR,—We shared Professor Pickles's experience of receiving remarkably few reprint requests to our spoof letter (*Nature*, February 14, 1970). So far, there have been five or six from Europe, two from the United States and assorted requests to know the result of the experiment or to have a reprint, while pointing out that they had read the letter. Perhaps people in the latter category acquire all of *Nature* by reprint request rather than paying 4*s* weekly. An interesting request, and one which we find not uncommon, is for the wrong reprint. In this case we were asked for a paper in *Biochemical Journal*, and we can only surmise that an unfortunate secretary has slipped a line on a print-out and sent the wrong request to hundreds of authors.

We agree that republication in *Dateline in Science* did our cause no good and are sorry that what we regarded as a delicate flower which would take a month or two to bear fruit had to be pulled up by its roots in an early stage to fill a spare column and receive a withering blast of publicity.

But perhaps we are pessimistic about the all-rounder. Perhaps child psychiatrists are interested in the development of the Red Sea.

It has occurred to us that the words "Plate" and "Red" in a recent paper[1] may afford us a chance to catch the haematologists. We are only sorry now that we did not make the title "Plate Tectonics of the Red Sea; an Embryo Ocean".

Yours sincerely,

D. DAVIES

Are More Airports Necessary ?

SIR,—A recent editorial comment (*Nature*, April 25, 1970) suggests that the advent of the 300 m.p.h. hovertrain "may be the signal to banish the new airport once and for all from the heavily populated areas around London". When the full implications of high-speed surface transport are taken into account we may be able to enlarge the point with economy of words by stopping at the phrase "once and for all".

Let us first consider the effects of a rapid-transit line connecting the airports of Gatwick, Heathrow, Birmingham, Manchester, Prestwick, Abbotsinch and Edinburgh, with the additional assumption that these airports (and, perhaps, other convenient stations on the high-speed spine) would be connected to city centres by intermediate speed (say 100 m.p.h. train) collecting links.

The total length of the main line (which could follow existing motorway routes for much of its length) would be about 480 miles, corresponding to a non-stop journey time of about 1·75 h from one end to the other. Given a peak acceleration of $0{\cdot}1g$, total acceleration time from a standing start would be about 3 min, and each 2-min stop would therefore add about 5 min to the journey. If the whole line had eight or nine stations on it, the journey time from end to end would be about 2·5 h, and an average journey might take a little over an hour. These figures are seen to be comparable with road or conventional rail journeys from London to any of Roskill's four sites.

The immediate effect of such a system would be to eliminate the need for the great majority of internal flights, and to permit overseas flights to be redistributed between airports. At present, flights between the airports mentioned account for about 12 per cent of the London load, and this figure can be doubled for the UK as a whole because there is an aircraft movement at a provincial airport corresponding to every domestic flight entering or leaving London. If this ratio is maintained as London traffic expands, we see that four-runway capacity in the London area ties up a total of one runway in the UK on domestic traffic. Eight-runway capacity for London ties up two UK runways. The traffic figures for the other airports on the list indicate spare capacity, by London loading standards, of at least three runways. The case for adding four new runways in the London area thereby loses its validity.

The foregoing case has been based on the gross capacity of only seven airports, but the actual reserve in Britain is far greater than this. The 1968–69 report of the British Airports Authority lists twenty-seven mainland airports carrying year-round scheduled services, and suggests that sixteen of these (excluding the third London airport) would be viable in the 1980s. In fact, most of these would be considerably under-used on the Authority's assumptions, but several could be linked to our transport spine to provide reserve or additional scheduled capacity.

The use of high-speed surface transport would reduce the problem of scheduling interconnecting flights from the various airports to about the level of that which was previously envisaged for the London airport system. The increased geographical dispersion would greatly improve the options of flight diversions to avoid unfavourable weather conditions and would also reduce the problem of air space congestion. By extending the transport spine to the point of entry to the Channel Tunnel, the problem of dispersing surface traffic from Europe would be alleviated, and if the system could be extended into Europe the airport pressure resulting from European traffic would be reduced.

On the basis of the suggested capacity for the third London airport, it would appear that the transit system should be designed for an ultimate capacity of at least 100 million passenger movements per annum. In the proposal for a tracked hovercraft, each vehicle is taken to have 200 seats. Taking an average journey lasting one hour, and assuming seat utilization of 2,500 h per annum, the number of passenger seats needed is 40,000, and about 200 vehicles are required. These vehicles, operating on a five-hour round trip, could provide peak service at intervals of about 1·5 min in each direction. Safety requirements would, perhaps, require the individual vehicles to be grouped into trains under these maximum-density conditions, but this further step would mean that even higher passenger flows could be sustained if necessary.

We now see that we have the beginnings of a transport hierarchy which can be extended downwards to connect with urban services. If such a hierarchy is built up on the principle of dynamic similarity between levels (the same peak acceleration, and similar journey shape), the time required for each stage is proportional to maximum veolicity, and the length of each stage is proportional to the square of the velocity[1]. We can also show that the rate of acceleration through the hierarchy (ignoring time lost in changing vehicles) is of the form

$$a = a_0(R-1)/R^2$$

where R is the speed ratio between two stages and a_0 is a measure of the acceleration in any one stage. Thus $R=2$ is the theoretical optimum on the elementary theory, but would be inconvenient in practice because of the excessive number of changes. $R=3$ seems a reasonable compromise.

On filling out the hierarchy in this way, we would envisage pedestrians boarding local buses to accelerate to about 10 m.p.h., and these serving high-speed buses or local rail feeders moving at 30 m.p.h. Theoretical average stage lengths would then scale as follows:

300 m.p.h. hovertrain	90 miles
100 m.p.h. feeder train	10 miles
30 m.p.h. coach or local train	0·9 mile
10 m.p.h. local bus	0·1 mile

Considerable adjustment of actual stage length to suit the location of pick-up points can be accommodated without much loss of efficiency. We should recognize, however, that the concept of feeding aircraft with conventional surface vehicles (say 40 m.p.h.) implies a value of about 15 for R, so that the present painfully slow acceleration from walking pace to air speed reflects a gross design error in the conventional system.

In all, we see that the hovertrain opens possibilities for a massive reorganization of the worldwide pattern of passenger transport, whilst demanding little more than minor new development at the other levels of the hierarchy. Doubts about its commercial viability therefore seem strangely myopic.

Yours faithfully,
P. L. WILLMORE

International Seismological Centre,
Edinburgh.

Announcements

University News

Professor E. N. Hiebert, University of Wisconsin, has been appointed professor of the history of science in **Harvard University. Dr Clement B. Sledge** has been appointed professor of orthopaedic surgery at Harvard. He will be chief of the orthopaedic service at the Peter Bent Brigham Hospital and at the Robert B. Brigham Hospital. **Dr F. M. Ingersoll** has been promoted to clinical professor of gynaecology, and **Dr M. D. Schulz** to professor of radiation therapy at the Massachusetts General Hospital.

The title of Professor of Chemical Pathology has been conferred on **Dr F. V. Flynn,** in respect of his post at University College Hospital Medical School, **University of London.**

Dr G. P. Dinneen has been appointed director of the Lincoln Laboratory, **Massachusetts Institute of Technology,** in succession to **Dr M. U. Clauser** who has resigned to become academic dean of the **US Naval Postgraduate School** at Monterey.

Appointments

Professor J. W. L. Beament, University of Cambridge, and **Professor R. W. Edwards,** University of Wales, have been appointed members of the **Natural Environment Research Council.** Professor Clapham, Professor Lighthill, Sir Maurice Yonge and Sir Frederick Bawden will retire from the Council on May 31, although Sir Frederick will continue to attend meetings in his capacity of assessor for the Royal Society.

Miscellaneous

Applications or recommendations for the **Corday-Morgan medal and prize** are invited by the Council of the Chemical Society. Three awards for experimental work in different branches of chemistry will be made for 1969, each consisting of a silver medal and a prize of 250 guineas. Candidates should be British and under the age of 36 when the work was published. Further details can be obtained from the Scientific Affairs Officer, Chemical Society, Burlington House, London, W1V 0BN.

The Trustees of the **Beit Memorial Fellowships for Medical Research** have elected the following junior fellows: **C. T. Kirkpatrick,** to work at the Queen's University of Belfast; **Y. K. Levine,** to work at the MRC Molecular Pharmacology Unit, Cambridge; **W. Montague,** to work at the University of Sussex; **A. C. R. Samson,** to work at the University of Leicester; **M. A. Chester,** to work at the Lister Institute of Preventive Medicine; **G. E. Morris,** to work at the University of Sussex; **D. J. Warren,** to work at the Radcliffe Infirmary, Oxford; **M. T. Wilson,** to work at the University of East Anglia; **M. R. C. Winter,** to work at the University of Birmingham; **Miss G. M. Air,** to work at the MRC Laboratory of Molecular Biology, Cambridge; **M. J. Clemens,** to work at the National Institute for Medical Research, Mill Hill.

Professor Robert A. Good, Regent's professor of pediatrics and microbiology at the University of Minnesota, is to receive the **Howard Taylor Ricketts award** for 1970.

Sabbatical Itinerants

In the hope of providing some practical assistance in the good cause of mobility between laboratories, *Nature* advertises the needs for housing of families about to take up periods of sabbatical leave. To begin with, no charge will be made for advertisements like this. It is hoped that a period of experiment will show what form these advertisements could most usefully take and whether they are effective.

Vacant: From October 1970 for 1 year, fully furnished 3-bedroom house in North London. Close to Northern Line (Whetstone–Totteridge station) with easy access to city centre. Central heating, garage and garden. Prefer **exchange** with similar in Boston–Cambridge, but will consider rental. Please contact Dr C. Hughes, National Institute for Medical Research, London NW7.

Wanted: 4-bedroom furnished house or apartment convenient for commuting to University College, London, from mid-September 1970 to July/August 1971. Could **exchange** for use of 5-bedroom house in Seattle, near University of Washington. Please contact Professor M. M. David, Chemical Engineering Department, University of Washington, Seattle, Washington 98105, USA.

Wanted: From January 1971 to December 1971, furnished house or apartment, 3 bedrooms with central heating, either within walking distance of University College, or on west or south-west side of London with good transportation, for professor, wife and three children, ages 9, 7 and 4. Please contact Dr Harold J. Bright, Department of Biochemistry, School of Medicine, University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA.

Wanted: Furnished London home within 30 min of WC1 for 12 months starting September 1, 1970, for professor with young family. Central heating, 2–3 bedrooms, less than £65 monthly. Please contact Dr A. Kalantar, Chemistry Department, University of Alberta, Edmonton, Canada.

British Diary

Monday, June 1

Immunological Tolerance: Its Possible Role in Organ Transplantation (5 p.m.) Professor L. Brent, University of London, at the Wright-Fleming Institute, St. Mary's Hospital Medical School, Norfolk Place, London W2.

Tuesday, June 2

Magnetism (5.30 p.m.) Sir Lawrence Bragg, CH, FRS, Royal Institution, at 21 Albemarle Street, London W1. (Lecture for Fourth Form pupils from Schools in London and the Home Counties. To be repeated on June 3, 9 and 10.)

Management and Automation in the Petroleum Industry (four-day conference) Institution of Electrical Engineers, in association with the Institute of Petroleum, the I.Mech.E., the I.Chem.E., and the Inst.M.C., at Bath, Somerset.

Summer Meeting (five-days) Institution of Electrical Engineers, at Bristol.

Wednesday, June 3

Rotational Fabrics in Syntectonic Crystals, Dr D. W. Powell and Dr J. E. Treagus (demonstration); **Exhibit of Geological Map and Sections of the Kyrenia Range, Cyprus,** Professor W. D. Gill (demonstration); **The Structure of the Gulf of Suez (Clysmic) Rift,** with special reference to the Eastern Side, Dr D. A. Robson (paper, 5 p.m.) Geological Society, at Burlington House, Piccadilly, London W1.

Thursday, June 4

Cryosurgery in Surgical Practice (5.15 p.m.) Professor Sir James Fraser, University of London, in the Page Street Lecture Theatre, Westminster Medical School, Horseferry Road, London SW1.

Numerical Analysis of Partial Differential Equations (9.45 a.m., two-day discussion meeting) Royal Society, at 6 Carlton House Terrace, London SW1.

Friday, June 5

Clinico-Pathological Correlation in Biliary Tract Disease (11 a.m.) Mr N. Keddie, University of London, at the Royal Postgraduate Medical School, DuCane Road, London W12.

Saturday, June 6

Aspects of Bone Disease (10 a.m. symposium) British Institute of Radiology, at Queen Elizabeth Hospital, Edgbaston, Birmingham 15.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire	**£14.0.0** each
United States of America (by air freight)	**$48** each
Canada (by air freight)	**$52** each
Elsewhere overseas by surface mail	**£14.0.0** each

(Charge for delivery by air mail on application)

*Shorter periods *pro rata*. (Minimum three months.)

APPOINTMENTS VACANT

UNIVERSITY OF STRATHCLYDE

Department of Applied Microbiology

RESEARCH ASSISTANT

(Reference A.M.39)

or

SENIOR TECHNICIAN

(Reference A.M.40)

Applicants must have experience in Microbiological and/or Biochemical techniques. Preference will be given to holders of a suitable degree or H.N.C. qualification or its equivalent. Duties are concerned with industrial contract work, in the Centre for Industrial Innovation, under the Department of Applied Microbiology.

Salary within range: Research Assistant, £1,000 to £1,400; Senior Technician, £1,278 to £1,586.

TECHNICIAN

(Reference A.M.41)

also required for the above work. Applicants should have O.N.C. or equivalent qualifications.

Salary scale: £935 to £1,303.

Holiday arrangements honoured.

Applications in writing, quoting reference numbers, giving details of age, experience and qualifications, to Mr. G. M. Boyd, Finance Office, University of Strathclyde, George Street, Glasgow, C.1.

(2106)

UNIVERSITY OF YORK

DEPARTMENT OF BIOLOGY

ANALYTICAL TECHNICIAN

required for research project on reclamation of coal-mine waste for plant growth. Duties include plant analyses, analysis of colliery spoil and some developments of appropriate methods of analysis. Well equipped laboratory with facilities for atomic absorption spectrophotometric and calorimetric techniques. Salary according to age and qualifications in scale £935 to £1,303 per annum.

Applications, including details of experience and addresses of two referees, should be sent to the Bursar, The University of York, Heslington, York, not later than June 30, 1970. (2112)

TECHNICAL INFORMATION

HEAD OF DEPARTMENT

The Research Division of Pfizer Limited was created in 1957 and since that time has expanded steadily and now employs some 450 people, 200 of whom are scientists in various disciplines: chemistry, biochemistry, pathology, pharmacology, bacteriology, virology, parasitology, veterinary science and medicine. Its direct research expenditure is over £1.7 million in 1970.

The Technical Information Department provides an information and library service to all departments in the Division, and on occasion to other parts of the Company.

We need a graduate in chemistry or a biological science, preferably with some years experience of medicinal chemistry and an appreciation of disciplines other than his own to assume the responsibility for organising and maintaining the services. He will be required to develop these against the background of increasing emphasis on mechanisation and the growing interaction of the department with the information group of the parent company's research division in Connecticut.

Ideally candidates will have previous experience of information work; applicants without this should not be deterred, however, since training will be given where necessary.

The critical features of the appointment are an interest in technical information work, administrative ability and energy, and could suit the younger person who is looking to make his long term career in technical information. Age, however, is not a barrier in this job.

We have in mind a starting salary from around £3,000 per annum which will depend on background and experience. The conditions of employment include pension and death benefit scheme, bonus scheme, and the payment of removal expenses, if appropriate.

Applications, in writing, to:

Pfizer

D. W. Sells, Personnel Manager,
Research Division,
Pfizer Limited,
Sandwich, Kent.

(2158)

TRINIDAD & TOBAGO COCONUT RESEARCH LTD.

There is a vacancy for an AGRICULTURAL SCIENTIST in this organisation and applications are invited. The duties of the successful candidate will be to work on a research programme involving different problems in coconut cultivation, especially Red Ring disease, and they will include a considerable amount of field work. Salary will be in the range of £2,400 to £3,000 per annum, and a three-year contract will be offered in the first instance. The exact point in this scale at which the successful candidate will enter, and the precise level of responsibility to be assumed, will depend upon experience and qualifications.

Applicants should hold a degree in Agriculture or in the Natural Sciences and should have had a number of years' experience in Field Experimentation.

Applications and requests for further information should be addressed to:

Trinidad & Tobago Coconut Research Ltd.,
P.O. Box 295,
Port of Spain, Trinidad, W.I.

(2157)

BOC

Chemists for Isotope Production

PROCHEM, recently acquired by the BOC Group and now part of Special Gases, manufacturers stable isotopes for commercial and medical use. Prochem has an established export market and there is considerable expansion potential.

The Senior Graduate for isotope labelling with C^{13}, N^{15}, O^{18}, should have prior experience on small scale organic synthesis in similar field. A substantial salary will be paid to well qualified experienced men to build up new section in this interesting field under the direction of Manager Prochem.

The Chemist with HNC chemistry or equivalent, to work in stable isotopes laboratory should have had a minimum of two years' laboratory experience in preparative organic and inorganic chemistry.

These appointments offer good opportunities to the right men; re-location allowances available where appropriate. Please write giving brief details of education and career to date or telephone for an application form.

P. G. T. Butler, Personnel Officer,
Prochem, Special Gasses,
Deer Park Road,
London SW19.
Tel: 01-542 6677.

(2189)

Huntingdon Research Centre

Research officer or assistant to work on quantitation of lung and skin irritation and the development of bioassays of irritant effects. The laboratory is equipped with the latest instrumentation for image analysis in pathology and carries out active research in this field. The post could suit either a research worker qualified to B.Sc. standard or an experienced technician holding FIMLT, AIMLT or HNC qualifications. Excellent opportunities for publications or thesis. The post is a responsible one and salary will not be less than £1,500 per annum.

Application to: **C. Urwin,**
Division of Pathology,
Huntingdon Research Centre,
Huntingdon.

(2135)

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF ANATOMY

Applications are invited from registered Medical or Science graduates, male or female for the post of LECTURER IN ANATOMY AND HISTOLOGY. The appointment carries responsibility for teaching preclinical medical students at ordinary and honours levels. Previous teaching experience is an advantage. The appointee must engage in research work and candidates with strong investigative inclinations will be favourably considered. Duties to commence October 1, 1970. Salary will be within the scale £1,355 by £125 to £3,105. Permanent appointment of medical graduates at not less than £1,585.

Applications (two copies), together with the names of three referees, should be received by the Registrar, University College, Cardiff, from whom further particulars may be obtained not later than June 12, 1970. Please quote ADV/465/N.

(2110)

UNIVERSITY OF DUBLIN
Trinity College

LECTURESHIP IN BIOCHEMISTRY

Applications are invited for the above post which has been established in conjunction with the Irish Flour Millers' Association.

The lecturer, who should have experience in the chemistry or biochemistry of proteins, will be expected to interest himself in research on the chemical and nutritional aspects of flour.

Salary Scale:
£1,650 × 67 – £1,985 (Merit Bar)
£2,088 × 67 – £2,892

It is not expected that an appointment will be made above the Bar in the Lecturer's scale.

Marriage and children's allowances are paid and there is a non-contributory F.S.S.U.-type pension scheme.

Further particulars may be obtained from:
The Assistant Secretary (Staff),
Trinity College,
Dublin 2.
who will receive completed applications up to June 22, 1970.

(2109)

WESTFIELD COLLEGE

(UNIVERSITY OF LONDON)

Applications are invited for the post of

TECHNICAL ASSISTANT

to operate a nuclear-magnetic resonance spectrometer (A 60/A) in connection with the M.R.C. Steroid Reference Collection and also with research in inorganic and organic chemistry.

Salary within the range £1,250–£1,500 per annum depending upon qualifications and experience.

For further details write to Dr. D. N. Kirk, Chemistry Dept., Westfield College (N), Hampstead, N.W.3, to whom applications should be addressed before 30th June, 1970.

(2203)

PAPUA AND NEW GUINEA INSTITUTE OF TECHNOLOGY

(formerly Institute of Higher Technical Education)

Applications are invited for the following appointments in the School of Engineering:

SENIOR LECTURESHIPS AND LECTURESHIPS (4) IN CIVIL ENGINEERING

SENIOR LECTURESHIP AND LECTURESHIP IN ELECTRICAL ENGINEERING

SENIOR LECTURESHIP AND LECTURESHIP IN MECHANICAL ENGINEERING

Candidates should have good honours degrees with experience of teaching in a tertiary institution, in research and in industry. The Institute is responsible for the professional and diploma training in technical subjects in the territory. The first stage of the engineering building was completed at the end of 1969. The Institute has been charged with responsibility for research and development in the territory; work has already been started in a number of topics and others are planned.

SALARIES (at present under review):

SENIOR LECTURER: $A8,000 by $A250 to $A9,250 per annum.

LECTURER: $A5,900 by $A270 to $A7,520 by $A280 to $A7,800 per annum.

An additional allowance of $A360 is normally paid to married male staff. Appointments are normally on 3-year and 6-year contracts, with one year's study leave after five years' service, and furnished accommodation is available; taxation rates are about half those in the United Kingdom.

Further information about the Institute, method of application and conditions of appointment (including leave and passages, F.S.S.U. type superannuation, study leave, etc.) may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London, WC1H OPF.

Applications close on June 26, 1970.

The Director of the Institute (W. E. Duncanson, Ph.D.(Camb.), D.Sc.(Lond.), F.Inst.P., F.I.E.(Aust.), C.Eng.) will be in the United Kingdom for consultation and interviews up to mid-July. Contact with him may be made through the Association's office. (2183)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF BOTANY AND PLANT TECHNOLOGY

Applications are invited for the post of Lecturer in Plant Pathology. Preference will be given to those with special interest in the more experimental aspects of diseases of crop plants caused by bacteria and fungi.

Salary according to age and experience in scale £1,240 by £115 to £2,850 plus £60 per annum London Allowance (Salary and Allowance under review).

Applications, with a curriculum vitae and the names of two referees, should be sent to Professor C. P. Whittingham, Imperial College, London, S.W.7, to arrive not later than June 15. (2159)

WICKHAM RESEARCH LABORATORIES

LABORATORY TECHNICIAN REquired to take charge of Histology Department. Male preferred. Wide variety of work offered. A.I.M.L.T., F.I.M.L.T. or equivalent.—Winchester Road, Wickham, Hants. (2124)

PATHOLOGIST

An additional histopathologist is required to participate in research in our Toxicology Department, particularly with regard to the histopathology arising from toxicity tests on new medical products.

Applicants should hold a veterinary degree or other appropriate qualifications and have post-graduate experience in histopathology. This is a responsible position with good prospects for advancement.

Fisons Pharmaceuticals Limited is a rapidly growing research-based Company with Research and Development Laboratories recently transferred to new buildings which are still being extended, on the outskirts of Loughborough. The Laboratories are well staffed and equipped, and there are additional animal facilities at Hillcrest Research Station, 5 miles away near Belton.

The Salary will reflect the qualifications and experience of the successful candidate. We are a member of the Fisons Group providing a first class pension scheme, generous holidays assistance with removal expenses where necessary and other welfare benefits which come from being part of a large internationally known British Group. Applications quoting job reference No. 985 should be addressed to the Divisional Personnel Manager, Fisons Pharmaceuticals Limited, 12 Derby Road, Loughborough, Leics.

FISONS

(2126)

Plant Pathology Laboratory

CHEMIST

The Laboratory, which is part of the Ministry of Agriculture, Fisheries and Food, and located at HARPENDEN, HERTS., needs a Chemist (graded Experimental Officer/Assistant Experimental Officer) to join an expanding group concerned with plant and soil analysis for pesticide residues. Techniques used in this work include gas, paper, column and thin layer chromatography, spectroscopy and polarography. The group is investigating problems arising from the commercial use of insecticides, fungicides and herbicides and is also involved in the development of analytical methods for these compounds.

Salary: £1,020 (at 22)–£1,311 (at 26 or over)–£1,578; EO £1,725–£2,177.

Qualifications: Degree, HNC, or equivalent in appropriate subject. Age: AEO under 28; EO normally 26–30.

Prospects of permanent pensionable appointment. Prospects of promotion.

APPLICATION FORMS from the Director, Plant Pathology Laboratory, Hatching Green, Harpenden, Herts. **Closing date: 15 June 1970.**

(2123)

SCIENTIFIC CIVIL SERVICE

FISHERIES LABORATORY,
Ministry of Agriculture,
Fisheries and Food,
Burnham-on-Crouch, Essex

CHEMIST (graded Experimental Officer) required to develop a system of monitoring the occurrence and distribution of important polluting substances such as pesticide residues and heavy metals in the seas around Britain. The materials to be sampled and analysed may include fish, shellfish and other invertebrates, plankton, seawater and seabed materials.

The successful candidate will assist in the planning and organisation of an extended sampling system and take direct day-to-day responsibility for analysis within the laboratory. Duties may involve seagoing in the Ministry's research ships or in commercial fishing vessels.

Qualifications: See below. Extensive working knowledge of modern methods of chemical analysis and several years of practical experience in analytical work essential.

A starting salary above the minimum of the scale may be recommended.

Non-contributory pension. Prospects of promotion.

APPLICATION FORMS are obtainable by writing to the Civil Service Commission, 23 Savile Row, London W1X 2AA, or by telephoning 01-734 6010 ext. 229 (after 5.30 p.m. 01-734 6464 "Ansafone" service). **Please quote S/94-95/70/MAF/42/G. Closing date: 22 June 1970.**

FISHERIES LABORATORY,
Ministry of Agriculture,
Fisheries and Food,
Burnham-on-Crouch, Essex

BACTERIOLOGIST (graded Experimental Officer) to join a team engaged in marine pollution studies with particular interest in the effect of pollution on shellfish and inshore fisheries. The work is concerned with field investigations at many points around the coasts of England and Wales. Current projects include: adaptation of existing methods of mussel and oyster purification to new situations; studies of the multiplication of bacteria in stored shellfish; sanitary surveys of shellfish beds; the transmission of viruses and the heat sterilization of shellfish. The publication of results will be encouraged.

Qualifications: See below. Candidates should have extensive practical experience and wide competence in microbiological techniques, whilst a knowledge of methods of water examination is desirable.

Non-contributory pension. Prospects of promotion.

APPLICATION FORMS are obtainable by writing to the Secretary, Civil Service Commission, 23 Savile Row London W1X 2AA, or by telephoning 01-734 6010 ext. 229 (after 5.30 p.m. 01-734 6464 "Ansafone" service). **Please quote S/95/MAF/29/G. Closing date: 22 June 1970.**

MARINE LABORATORY,
Department of Agriculture and
Fisheries for Scotland,
Aberdeen

Three posts for **CHEMIST/BIOCHEMISTS and BIOLOGIST** (graded Experimental Officer/Assistant Experimental Officer).

Post 1. Chemist/Biochemist to work as member of a team engaged on the investigation of the biochemical and physiological effects of pesticides and related organochlorine compounds in fish.

Post 2. Chemist/Biochemist to work on analysis of micro-constituents in sea water and in marine organisms in a group studying the effects of pollution and marine food chains.

Post 3. Biologist to work in Demersal Fish Section on experimental work at sea and in aquaria, concerning growth and feeding habits of fish. Duties will include periods at sea and early morning attendance at the Fish Market to participate in the Laboratory's fish sampling programme. Men only should apply for this post.

Qualifications: See below. For post 3, experience of keeping fish in an aquaria would be an advantage.

Prospects of permanent pensionable appointments.

Prospects of promotion.

APPLICATION FORMS from Establishment Division, Room 171, St. Andrew's House, Edinburgh EH1 3DE. **Closing date: 15 June 1970.**

SALARIES, QUALIFICATIONS AND AGE LIMITS

EXPERIMENTAL OFFICER CLASS

A qualification of the standard of HNC or a general degree in an appropriate subject is normally required.

Starting salaries depend on age and experience in the range £741-£2,177.

Age: E.O. normally 26-30. A.E.O. under 28.

(2200)

BLUE CIRCLE
GROUP

polymer scientist

Applications are invited for the position of Polymer Scientist with the Product Research and Development Division of a progressive and expanding Group of Companies.

The successful candidate will have opportunities for research in the of field of polymeric materials and for promoting the development of new and interesting polymer based materials and processes.

Applicants should possess a good honours degree or equivalent and preferably have some experience in the surface coating, plastics or related fields.

A commencing salary will be negotiated according to experience and will be especially attractive to candidates between the ages of 28–42 years.

Applications with details of age, qualifications and experience should be addressed to:

The General Manager,
Associated Portland Cement Manufacturer Ltd.,
Research Laboratories, Greenhithe, Kent.

(2160)

UNIVERSITY OF EAST AFRICA
UNIVERSITY COLLEGE—DAR ES SALAAM

Applications are invited for the following appointments in the FACULTY OF AGRICULTURE:

PROFESSOR OF AGRICULTURAL ECONOMICS
PROFESSOR OF ANIMAL PRODUCTION
PROFESSOR OF AGRICULTURAL CHEMISTRY
LECTURER IN FOOD TECHNOLOGY
LECTURER IN SOIL MICROBIOLOGY/SOIL FERTILITY
LECTURER IN POLITICAL ECONOMY
LECTURER IN PEDOLOGY
FARM MANAGER (Senior Lecturer/Lecturer level)

Salary scales: Professor £EA3,150 per annum; Senior Lecturer, £EA1,950 to £EA2,615 per annum; Lecturer, £EA1,350 to £EA2,230 per annum (£EA = £1 3s. 4d. sterling). Salaries supplemented in range £612 to £1,068 per annum (sterling) and education allowances and children's holiday visit passages payable in appropriate cases by British Government. F.S.S.U. Family passages; biennial overseas leave.

Detailed applications (six copies), naming three referees by June 26, 1970, to Inter-University Council, 90/91 Tottenham Court Road, London, WIP ODT, from whom particulars are available. (2121)

A RESEARCH ASSISTANT REQUIRED TO study the movement of soil solutes in the root zone of soils. Applicants should have an interest in applying physico-chemical techniques to problems in soil and plant nutrition. Familiarity with electronics, computer programming and the use of radioisotopes should be an advantage. Salary in the range of £1,000 to £2,000 depending on experience.—Applications, in writing, should be sent by June 15 to the Reader in Soil Science, Department of Agricultural Science, Parks Road, Oxford, who will answer all inquiries. (2139)

Why Pye Chromatography

The crowning success in the design of complex analytical instruments is the achievement of simplicity. You will find it in Pye Analytical Gas Chromatographs.

Take the simple, functional glass-to-metal seal, for example. It makes column changing quicker and easier, improves sensitivity by reducing contamination of the gas stream and pushes the effective working temperature of glass columns up to 350°C.

Pye gas chromatographs are easy to use because we design them to give you what you want in instrumentation – accuracy, reproducibility, flexibility, simplicity.

Two systems are available, both with a wide range of optional modules—

The Pye Series 104 Chromatograph for research or routine work, with many accessories including wide-range amplifier and auto-solids injection . . . and the Pye Model R Research Chromatograph with modular column oven, unique "total-loss" cooling system and simultaneous two column multi-detector operation.

To learn more about Pye chromatography including industrial instrumentation, the GM60 Gas Chromatograph-Mass Spectrometer system and the DP90 Datacon computerised chromatograph system, write or 'phone today.

HIGH-SPEED DIAMOND WHEEL GRINDING MACHINE

Using the thin section grinding attachment accurate sections of Rocks, etc., can be produced mounted on 3″×1″ Microscopic Slides.

Model
LSC 100

For grinding both off-hand specimens and thin sections

of
ROCKS
CERAMICS
GLASS
REFRACTORIES
SEMICONDUCTORS
and all Hard
TEST SPECIMENS

The Machine is built of robust aluminium castings and is powered by *Brooks* split phase continuous rated motor controlled by a contactor with full overload protection and a waterproof push button control to give perfect operating safety even with wet hands.

Diamond Wheels 4″ or 6″ dia. × 1¼″ face width can be supplied.

Standard Voltage 230/250 volts 1 phase 50 cycles. Other voltages can be supplied to order.

The machine can also be used for Metallurgy specimens using bronze lapping plates instead of diamond wheels.

Who Should Count the Cost?

Mr Emilio Q. Daddario, the vigorous chairman of the House of Representatives Subcommittee on Science, Research and Development, has a great many friends and the best among them should tell him that he is barking up the wrong tree in trying to foist on the rest of Congress what he and Mr Charles A. Mosher call the Office of Technology Assessment (see page 894). The chief difficulty, all too apparent in the past few months, is that the doctrine of technology assessment has become one of those which are generously applauded even when their meaning is obscure. Briefly, the phrase is meant to evoke all kinds of perfectly proper sentiments about the need to make sure that the consequences of technical innovations are predicted as carefully as possible, preferably by making some attempt at a cost-benefit analysis. It first gained wide currency a year ago, when separate reports appeared in the United States by committees of the national academies of science and of engineering urging the need for technology assessment in language frequently so obscure that only the good intentions of the authors were permanently fixed in public consciousness. More recently, in November and December last year, Mr Daddario's subcommittee held a public inquiry on the subject which produced a long list of cautionary tales about the care which must be exercised in bringing new devices into service in the modern world, but which also saw the first signs of a movement now enshrined in the bill which Representatives Daddario and Mosher have introduced to provide Congress with an agency of its own specializing in technology assessment. Nobody will question their intentions, but there must be the gravest doubt about the feasibility of what they now propose.

The proposal for a congressional agency to help with making assessments of the value and of the consequences of technical development stems in part at least from the sense which must oppress a good many members of the Senate and the House of Representatives that the Administration is so well provided with technical assistance of all kinds that it can make rings round Congress on matters as diverse as the safety (or otherwise) of DDT, the advantages and the snags of supersonic transports and the sufficiency of particular programmes for the relief of water pollution. Is there not, in other words, a need that Congress should be better equipped to answer back? In terms like these, it is hard to deny the message in the bill. The question that should be asked, however, is whether the particular device which is now being advocated is the most suitable for its stated purpose. The question is of more general importance than its strictly American origins would suggest, for all kinds of legislative bodies in advanced societies find themselves increasingly at a loss to know how to make rational judgments on increasingly complicated technical questions.

The practical objection to Mr Daddario's proposal for an Office of Technology Assessment is that such an organization would have to be staffed by men of outstanding and almost unprecedented intellectual strength and moral virtue if it were to carry weight with the congressional committees which are most in need of the help which Mr Daddario is anxious to provide. The problem is well illustrated by the issue of the supersonic transport, also a live issue in Washington last week (see page 896). For several weeks, Senator Proxmire's subcommittee has been chivvying away at a score of witnesses representing as many different interests in the hope of forming a recognizable view of the importance and the disadvantages of the project. The fact that Senator Proxmire would probably be happiest if his inquiry sustains a case against the supersonic transport is probably irrelevant. The interest of the process has been the way in which it has uncovered disagreements within the government about the virtues of the project—Mr Russell Train, the chairman of the Environmental Council, turned out to be a surprisingly strong opponent. No amount of academic study by an Office of Technology Assessment could have uncovered this kind of internal conflict. To be sure, if the office had produced a formal report on the subject of supersonic flights, it would have been possible for congressional inquiries to proceed exactly as they do at present, but congressional committees would then find themselves in the unwelcome role of having to defend opinions of their own and not to challenge the intentions of the Administration. It is unthinkable that Congress would change its spots in such a casual fashion. The truth, of course, is that even matters of technology assessment are political issues in the broadest sense—settling the issue of the supersonic transport will require that somebody should balance the interests of those who want to have supersonic aircraft against the interests of those who wish that they will never fly. To the extent that the proposal for an Office of Technology Assessment would carry matters like these outside the realm of politics, it is unrealistic. The chances are that most people in Congress would regard it as such.

But if the Office of Technology Assessment is not the right instrument, what methods should be used for helping Congress to form a more balanced judgment about the advantages and disadvantages of innovation? To the extent that the task of Congress is to keep a sceptical eye on what the Administration is doing with public money, one of the most difficult tasks is to identify the problems where there is need to worry. A little thought will show that in many of the situations in which in recent months it has been necessary to put a stop to some accepted practice—the unrestricted use of DDT, for example, or the discharge of raw sewage into rivers—there has been no obvious occasion when Congress would have had natural cause to intervene at a somewhat earlier stage. The licensing of pesticides is, after all, a comparatively recent practice. Rivers have been regarded as open sewers for centuries. Moreover, the attempts—successful as they have been—to provide more rigorous public controls on practices like these have sprung from the proper activity of independent pressure groups bringing their case to Congress. In the clamour to be heard, those with sober warnings to give have been identified by the good sense of their case. If Congress really wishes to improve the degree to which society can control the uses made of new technology, the best thing will be to stimulate and to encourage the organizations which are independent both of the Administration and the legislature to make reasoned cases for or against particular innovations. Rather than setting up an entirely new organization to make academic studies of these matters, Congress would be better advised to be even more ready than at present to listen to what outsiders have to say.

But who is to provide not merely encouragement but money? The trouble, of course, is that making careful studies of the advantages of some technical innovation is a slow and expensive business. Even governments are not sufficiently contemplative and well provided with good technical advice to come to sensible decisions—a point well illustrated by the way in which the present Administration in the United States has banned the use of detergents containing phosphates from the beginning of next year without knowing whether the approved alternative (called NTA) may be even more damaging when it finds its way into sewage treatment plants. In circumstances like these, the best procedure would be to find some easily acceptable means by which independent studies of technical innovations could be financed by public money after having been approved by Congress. But is this not one of the ways in which the National Science Foundation could put some welcome flesh on the bones of its intention to spend more money on work which has some social relevance? What, in particular, is to prevent the National Science Foundation from spending money on studies intended to help with problems which worry Congress? The fact that it would often be necessary to go outside the universities proper to find suitable advisers is not to be scoffed at but rather welcomed.

Naming Mountains after People

One of the more informal means of patronage in the United States, and one of the most confusing, is the way in which mountains in Antarctica are named after living people, many of whom are distinguished administrators of science. Last week, on the twentieth anniversary of the setting up of the National Science Foundation, Dr Lee DuBridge, Scientific Adviser to the President, was told that the Board on Geographic Names had decided that a range of mountains in northern Victoria Land would in future be known as DuBridge Range. On the same occasion, Dr Philip Handler, who gave up the chairmanship of the National Science Board last week, was told that another inhospitable tract of Victoria Land, a ridge rising to more than 8,000 feet in what are called the Victory Mountains, will in future be known as Handler Ridge. Nobody expects that the two people whose names are thus made geographically permanent will ever climb the heights named after them. Indeed, it is no disrespect to either of them to wonder whether they will ever clap eyes on these outlandish places. No doubt they will have some splendid photographs to hang above the mantelpiece—the National Science Board took care that one of its members flew over the region in December—but that is likely to be the limit of their acquaintance with these places.

Several questions come to mind. Although the recognition of distinguished public service by the naming of a mountain may be less pernicious than the equivalent British practice of turning ordinary mortals into knights—Dr Handler is unlikely to find that people defer to him now that an uncared for part of Antarctica is named for him—the practice is an awkward break with the tradition that place names on the surface of the Earth should say something about those who have discovered them or, alternatively, should be named for some other characteristic—shape, position or function. To be sure, in the naming of geographical places, there has also been a tendency to honour patrons—the Renaissance explorers were keen on this and Antarctica itself already has several names with such an origin. But is it now intended that Dr

DuBridge and Dr Handler should be commemorated on the map as scientists or as patrons of science? And if the latter, should not the chosen names be those of presidents or politicians, not public servants who merely spend the money which the politicians have the ingenuity to raise? If, on the other hand, they are commemorated as scientists, is there not now likely to be a clamour for a much more widespread naming of places? After all, there are a great many glaciologists, to mention only one small group, with something of a right to have their names scattered on the ice. But if, as is more probable, the present practice is merely a piece of sentiment of the kind which in itself does little harm, is there not a case at this time, when scientific research in the United States is hard pressed for lack of funds, for saying that place names should not be given away, but sold? Rumour has it that in circumstances when the Liberal Party in Britain was short of money, the then Prime Minister, Lloyd George, made a substantial sum by selling knighthoods. Would it not be much more to the point if the Board on Geographic Names could be persuaded to sell off names in Antarctica to people willing to put up some fixed sum for scientific research? With luck, they could hope for $100,000 or so for every mountain peak and perhaps even $1 million for something as elaborate as a ridge or range. But if the sale were conducted by public auction, it would be a great public service to see who bids and for what.

100 Years Ago

NATURE

Fleas may live as long as nine months. Scarcely any observations have been made on the length of life in the molluscoidea and mollusca. Fish appear to have great tenacity of life. Thus, the carp is believed to have attained the age of 150 years, and the pike 267 years, if a ring with the following inscription is genuine—"I am the fish which was first of all put into this lake by the hands of the Governor of the Universe, Frederick II., the 5th of October, 1230." It weighed 350lbs., and was 19 feet long. Its skeleton was exhibited at Mannheim, and it was taken at Halibrun in Suabia in 1497. Of the Amphibia, the toad lives 36 years, the frog 12 to 16, and various tortoises are inferred to be of great age from their size. Amongst birds, the parrot, goose, falcon, and raven are long-lived, the two former reaching 100 to 120 years, and the two latter exceeding 150 years. Wrens only live two or three years. Amongst mammals, the whale and elephant have the longest term of life, both probably exceeding 100 years, and possibly reaching 200; horse 25, but occasionally reaching 40 years; ox 15 to 20 years; sheep and goat 12 years; lion 20 to 50 years; cat 9 to 18 years.

From Nature, **2**, **99**, *June* **9**, **1870.**

OLD WORLD

SOVIET UNION

Lysenko Rides Again

by our Soviet Correspondent

ZHOREZ MEDVEDEV, author of the history of the Lysenko period and until recently the director of the Laboratory of Molecular Radiobiology at Obninsk, has been arrested and detained in a mental hospital. This has emerged from protests signed by a particularly eminent group of Soviet scientists which includes Academician Andrei Sakharov, the nuclear physicist whose second critique of the Soviet system was published two months ago, the physicists Petr Kapitsa and Valentin Turchin, the biochemist Vladimir Engelgardt, the biologist Vladimir Astaurov and Aleksandr Tvardovskii, the recently dismissed editor of Russia's leading literary monthly, *Novyi Mir*.

Zhorez A. Medvedev.

Yet Dr Medvedev is at least as significant for Soviet science as those who have bombarded the authorities with telegrams on his behalf. When, on Friday, May 29, Medvedev was arrested at his home in Obninsk and removed to a mental hospital in Kaluga, some 120 miles from the capital, his twin brother, Roi Medvedev, stated that this was due to Zhorez having openly protested against the "senseless barriers" imposed by the Soviet authorities between communication and cooperation among Soviet scientists and their colleagues abroad, and against the system of postal censorship imposed by those authorities.

Roi Medvedev neglects to mention his brother's chief offence in the eyes of the government, which must surely outweigh any bootleg protest literature intended for internal consumption—the fact that Zhorez Medvedev is the author of the outspoken exposé of Soviet genetic policy under the Stalin regime, *The Rise and Fall of T. D. Lysenko*, which, in spite of the official retreat from Lysenkoist genetics and Stalinist policies during the mid-60s, could not appear in Russia because it is too critical of the regime, but which was published last year in English translation by the Columbia University Press.

The picture which Medvedev presents is one of scientific theories "tailored" to fit in with official philosophies and attitudes (the molecular theory of heredity was equated to Nazi racism, and hence not only condemned by academicians, but built up into a scientific bogeyman in the propaganda press), the supporting of the official theories of vernalization and nutrient-conservation by falsified evidence, false claims, or simple fiats in the form of telegrams from Lysenko to high-ranking officials.

Perhaps even more alarming than the excesses of Lysenkoism is Medvedev's answer to the question of how these happened. False doctrines, says Medvedev, are natural to science, they are "the extreme variants of essential hypotheses, assumptions and theories", which under the natural conditions of scientific progress will be eliminated by further experiments and by the free discussion and interchange of ideas with other researchers in the field or in allied fields. They can achieve "a monopolistic position only in state systems that are extremist in nature, as a particular manifestation of many other deviations from the norms of organized human society".

Shortly after the appearance of his book abroad, Medvedev was dismissed from his post as director of the Laboratory of Molecular Radiobiology at the Institute of Medical Radiobiology in Obninsk. His present confinement in the mental hospital will prevent him from attending an international conference on genetics. The telegrams of protest resulted in the dispatch to Kaluga from Moscow of a special psychiatric commission, which pronounced him normal, but recommended that he be kept in hospital for a further week—apparently as a face-saving measure. Clearly, Medvedev is seen as an opponent, not only of the Stalinist personality cult and the excesses which it produced, but of present policies also. It is noteworthy, perhaps, that another protest organized by Academician Sakharov denounced the holding in a mental hospital of Major-General Petr Grigorenko, who wrote a clandestine article in favour of the now-banned work of the historian Aleksandr Nekrich, *June 22, 1941*, an indictment of Stalin for ignoring the Nazi threat to Russia and by weakening the defence capacity of the Soviet Union. The rehabilitation of Stalin has been in progress for some time now. The Medvedev affair could be a sign that Lysenko may be due for rehabilitation in his patron's wake.

INVENTIONS

Resolving a Patent Muddle

WITH patent offices around the world breaking down largely because of the pressure of patent applications from abroad, two agreements which could ease the load are being hammered out. In Washington the Patent Cooperation Treaty is being negotiated and could even be signed within three weeks. This would ease the pressure on patent offices by sharing the work of checking whether an invention has been anticipated, but the granting of patents would still be up to the national patent offices. A more radical scheme, but one which is limited to western Europe and is not so truly international, is being discussed by eighteen countries including Britain. This aims at the setting up of a European Patent Office and involves some decline in the status of national patent offices.

Although a draft convention that deals with the way patent applications would be treated under the European scheme has already been published, the establishment of the scheme seems to be four or five years away. An international patent system has been as elusive as the philosopher's stone for more than a century, and there are many obstacles in the way of a European agreement. For example, there is the question of what is patentable—in Italy pharmaceuticals are excluded—and the durations of patents differ from one country to another.

The eighteen countries involved in the European negotiations are the EEC and EFTA countries together with Greece, Ireland, Spain and Turkey. The scheme is to consider the mechanism of patenting in two parts: what happens before a patent is granted and what happens afterwards. After a year's intensive effort the first part of the process has been covered by a draft convention, which envisages that a European Patent Office would examine applications for novelty in particular, and would grant patents that would be effective in all the eighteen countries. The location of the European office is still the subject of bargaining, but The Hague and Munich are believed to be candidates, and the possibility of some applications being examined in branch offices, for example in London, is not ruled out.

Once a patent is granted the next step depends on whether or not the state is a member of the EEC. For the purposes of the European patent the EEC is treated as a single country and a uniform legal system, under which the European patent will have force throughout the EEC, will be established to deal with such matters as patent infringement.

A European Patent Office could find itself dealing with something like 40,000 applications a year, and despite the difficulty of estimating the running costs of an international organization it looks as if the system will lead to savings for anyone who wants to file a patent in three or more countries.

The diplomatic conference on the European agreement is unlikely to take place before 1971. In the meantime there is the Patent Cooperation Treaty being negotiated in Washington which involves a number of offices to which patent applications will be sent for a report on novelty. After eighteen months the application is then published together with a list of the documents where the invention has been anticipated. It is then up to the national patent office whether or not to grant a patent. There are likely to be searching offices in the United States, Germany, the Soviet Union, Japan, and in The Hague, where the International Patent Institute is sited, which will also be the searching authority for the European scheme.

Although in principle the national offices will be able to ease the load by delegating the search procedure through the treaty, it remains to be seen to what extent the national offices are prepared to do this. In the end economic necessity will be the driving force.

LUNAR SAMPLES

SRC asks for More Moon

by our Astronomy Correspondent

Applications by British scientists for samples from the next batches of Moon rock and dust are expected to be forwarded to NASA within the next few days, just as soon as the applications have received the stamp of approval of the Space Policy and Grants Committee of the Science Research Council. Last week the applications were vetted by the Lunar and Planetary Panel, the committee of the SRC under the chairmanship of Professor K. Runcorn that deals with the lunar samples programme. It is believed that proposals from twenty-five groups will be forwarded to NASA, including experiments suggested by groups which properly come under the Natural Environment Research Council, and by groups in government laboratories.

The SRC is of course the scientific agency in Britain with which NASA deals and through which all applications for lunar material have to be channelled. Fifteen teams in Britain were on the SRC list for receipt of samples from the Apollo 11 and Apollo 12 missions, so it seems that interest has widened considerably. But the SRC is not saying at this stage what new experiments are being proposed, or indeed who the experimenters are, although it appears that no out of the ordinary proposals have been put forward. It seems safe to assume that the samples will be subject to a similar battery of tests as before: mineralogical and petrological examination, elemental analysis, age determination, examination for organic chemicals, analysis of physical properties (notably magnetism and luminescence), and so on.

The applications are for samples of the material which will be returned by the remaining Moon missions, Apollos 14 to 19. But the Science Research Council believes that NASA will provide further opportunities to apply for samples as the Apollo programme develops.

Nevertheless, there is still concern among scientists in Britain that liaison between the SRC and NASA is not as good as it could be. Complaints that NASA is weak on giving advance notice of opportunities to participate in space experiments are common, although this seems to be a problem that also afflicts scientists in the United States. But with interest in lunar and planetary science booming in Britain, and the omens good for the proposed school of planetary science at Lancaster University, people are looking for closer contact with the American programme. One idea which has been put forward by NASA is for a British scientist nominated by the SRC to work at Houston taking an active part in the Manned Spacecraft Center. The SRC refuses to comment because the NASA offer is apparently unofficial at present. People in the planetary sciences were hoping that the SRC would jump at the chance.

POLLUTION

Booms Banned; Exhausts Exempted

Noise and smoke are the chief targets of the White Paper on the environment published by the British government on May 28. If the government is re-elected, commercial supersonic flights will not be allowed to make sonic booms overland, and existing aircraft may be required to be quieter in taking off and landing. Heavy road vehicles will have to be checked annually for noise, and all new vehicles will need to be fitted with a device to reduce emissions of unburned hydrocarbons. More industrial processes will come within the scope of the Alkali Act, which controls air pollution, and reluctant local authorities in badly polluted areas will be compelled to ban domestic coal fires. Together with proposals for cleaning up land and water, these plans for legislation would be put into action during the lifetime of the next government, the Secretary of State for Local Government and Regional Planning, Mr Anthony Crosland, said when he introduced the White Paper (*The Protection of the Environment*, HMSO, London, 15p).

By deciding to outlaw the sonic boom, the government has reduced the potential sales of the Concorde (although the British Aircraft Corporation has always assumed in its sales projections that Concorde will be banned from flying overland), and other countries beneath the transatlantic air routes from Europe have already indicated that they intend to ban supersonic overflying. Without a ban by Britain, Concorde might sell 80 per cent more than the 250 planes expected to be sold by 1980. But those who have been complaining that the Concorde project puts profits before people are heartened by the decision, and the Noise Abatement Society talks of the proposal to ban overland commercial flights as a "splendid achievement", even though supersonic test flights over Britain this summer are to continue.

The proposals for clean air have been greeted with more scepticism. The trouble is that next winter there will not be enough smokeless fuel to go round because the output of gas coke has fallen now that natural gas is widely used, and many smoke control orders are being suspended to allow people to heat their houses with coal. As a result, the White Paper admits that the clean air programme will have to be delayed. This does not please the director of the National Society for Clean Air, Rear-Admiral P. G. Sharp, who is not confident that government plans for keeping open a few uneconomic gas works will be enough to solve the fuel shortage quickly. He would like to see more encouragement now instead of later as the White Paper implies, for people to use electricity, gas or oil instead of solid fuels. He is also disappointed that there are no plans for reducing the carbon monoxide content of vehicle exhausts—Mr Crosland's view is that the British climate does not warrant such drastic measures as are necessary, for example, in Los Angeles, even though the Economic Commission for Europe has recommended a general reduction of carbon monoxide emissions.

On waste disposal and water pollution, the government will let itself be guided by some half-dozen official reports which are due to appear within the next year, but it promises eventually to undertake a national clean rivers programme and will, in any case, be restructuring the water and sewage industry when the pattern of local government is reorganized. The White Paper is more specific about the penalties that should be imposed for pollution offences, which at the moment are absurdly small (£100, for example, for illegal discharges into rivers). These fines, the White Paper says, should be "brought into line with the realities of modern life", and the recent Oil in

Navigable Waters Bill has already made a start by providing for an increase from £1,000 to £5,000 in the fine on summary conviction for the master of a ship which illegally discharges oil into the sea.

CS GAS

Infringing the Gas Laws

THE British government's decision to regard CS gas as being outside the scope of the Geneva Protocol on chemical and bacteriological weapons came under attack from several quarters at a meeting of the British Pugwash Group last week. It was unfortunate that the debate took place in something of a vacuum since the top billing for the meeting, Lord Chalfont, was prevented by the election from explaining the logic of the government's position and no understudy from the Foreign Office was prepared to stand in at short notice. Lord Chalfont's absence forced participants to speculate about the official reasons behind the decision, and most of them had considerable difficulty in finding any logical arguments to back it up.

Professor Andrew Martin, QC, professor of international law at the University of Southampton, argued that the decision cannot really be justified on the grounds that CS is, in Mr Stewart's words, "not significantly harmful, except in exceptional circumstances", because the Geneva Protocol itself makes no distinction between lethal and non-lethal weapons. The protocol prohibits the use in war of "asphyxiating, poisonous or other gases, and of all analogous liquids, materials or devices", and its interpretation hinges to some extent on the phrase "other gases"—particularly because the equally authentic French version uses the phrase "ou similaires". In 1930, the British government issued a memorandum in which it said that tear gases fall within the scope of the protocol, and last July U Thant, Secretary General of the UN, called upon member states to make a clear affirmation that the protocol applies to all chemical, bacteriological and biological agents. What, then, has induced the British government to reverse its former declaration and to ignore U Thant's plea ?

One of the more popular explanations canvassed at the meeting was that the government was considerably embarrassed by using CS to control its own citizens in Ulster, and at the same time giving an undertaking not to use it against an enemy in wartime. But in any case, there is nothing in the protocol which prohibits its use for riot control, and the government was not acting illegally. Moreover, France stated categorically last December that it regards CS as prohibited in warfare, in spite of the fact that it is often employed for riot control in the streets of Paris. Another explanation which seemed plausible to some was that the British government's decision was in part a gesture of solidarity with the US, which has never signed the Geneva Protocol and is using vast quantities of CS on the battlefield in Vietnam.

The most logical explanation for the government's decision is, however, that it believes that CS is more humane than bullets for overcoming an enemy. But even this explanation sounded less than convincing to most participants at the meeting, because it is invariably used in wartime in conjunction with conventional weapons, and is therefore often just a forerunner to bullets. In any case, the lack of published material about the toxicity of CS gave rise to fundamental disagreements among the speakers about the dangers of using the weapon. Professor R. B. Fisher, of the University of Edinburgh, for example, maintained that the concentration of CS needed to cause significant physiological damage is several orders of magnitude greater than the concentration that can be tolerated, and that it is therefore unlikely that anybody could be exposed for long enough to suffer serious harm, unless he were incapacitated. On the other hand, figures quoted by Dr Julian Perry Robinson and Dr G. R. N. Jones suggest that doses of CS which would cause serious damage and even death might be much lower than Professor Fisher's estimates. The effect of CS on the eyes is also rather uncertain.

In any case, as Professor Fisher pointed out, it is illogical to campaign against CS on its own. The most important issue is to get the government to state that all chemical agents, including tear gases, are covered by the Geneva Protocol.

ZOOS

Acknowledged to Exist

THE response of the British government to the management consultants who recommended financial aid for the Zoological Society has been to provide £1,350,000 towards rebuilding and payments of debts, and to waive repayment of a loan of £125,000 made to the Society in 1964. Mr John Silkin, Minister of Public Building and Works, acknowledged in the House of Commons last week that the zoo has become, in fact if not in form, a national institution which is an important London amenity and tourist attraction.

The management consultants were called in by Mr Silkin's predecessor, Mr Anthony Greenwood, who announced last year a short-term government loan of £375,000 for the Zoological Society. This was in recognition of the mounting financial difficulties of a society that had always remained independent of government subsidy. The society's spectacular success in raising £3·5 million during the past ten years had not been enough to avoid deficits of £30,000 in 1968 and £54,000 last year.

After examining the details of the society's affairs at London Zoo and Whipsnade Park, the consultants passed the organization with a clean bill of health, and concluded that financial stability could be achieved in the longer term with government help and the continuation of efforts to cut costs and increase revenue. The government was recommended to repay the short-term debts incurred by the society's extensive rebuilding programme, which reached the half way mark two years ago with the opening of a new small mammal house. A contribution to the cost of the remaining part of the rebuilding programme was also called for, and has been provided in the form of £700,000 to be spent during 1970–74. To repay the short-term debts, £650,000 will be provided from the Civil Contingencies Fund, and the government loan of £125,000 made to the society in 1964 will not now have to be repayed.

This money will complement the society's own efforts to make ends meet during the present time of trouble. Among the consultants' other proposals for increasing revenue was an increase in subscriptions from scientific fellows and associates, which is now under consideration. Benefactors, of course, continue to be generous; £125,000 was received recently for the building of a new primate house. The charge for admission to the London Zoo was increased in May from 7*s* 6*d* to 8*s* 6*d* for adults, and the question of further increases is under review.

The society has also been rigorous in making all possible economies, and at the annual general meeting on May 20 the secretary, Sir Solly Zuckerman, said that costs had miraculously been cut by 2 per cent during the past year, in spite of the many improvements that had been effected.

Sir Solly also said that the council of the society is hoping that by the end of the 1970s there will be an endowment fund to take care of all redevelopment needs. The Zoological Society evidently intends to continue to cherish its independence.

COMPUTER BOARD

Finney for Flowers

Next month Professor Sir Brian Flowers is to relinquish the post he has held for four years as chairman of the Computer Board, in favour of Professor D. J. Finney, University of Edinburgh. Professor Finney, who is director of the Agricultural Research Council Unit of Statistics, has been a member of the Computer Board since it was set up in 1966 and is expected to continue the board's policy of promoting regional computing centres around the country.

One of the first tasks facing the new board is to see how much of the original idea of regional computing centres can be salvaged. As Professor Flowers explained last year, there seems no way of preventing a university selected as the centre for a region from taking up an unfair share of the computer's time. It is one thing for the Computer Board to urge a university to provide facilities for other universities, he said, but it is another matter to make a centre truly regional.

Professor Finney is unlikely to lead his seven man board far away from the guiding lines laid down by the original Flowers report, which chose London and Manchester to be the major computing centres in Britain with Edinburgh as a special centre based on a multi-access system; this would be later followed by a further concentration of special facilities into regions. But the extent to which the board will have to modify this scheme, as intimated by Professor Flowers when he opened the new centre at King's College, London, last year, is likely to depend on whether the development of more powerful computers can keep pace with the rising demand for facilities. Another decision facing the board is whether or not to introduce a system of charging for university computing.

MATHEMATICS

'Q' and 'F' a Bar to Prodigies

The Joint Mathematical Council has joined the swelling ranks of those who are worried about the proposals for 'Q' and 'F' level examinations in the sixth form. In a statement which is being sent to the Schools Council, the JMC has expressed concern that the proposals will hold back the mathematically gifted child and will exacerbate the shortage of mathematics teachers. But the council is prepared to admit that the scheme holds advantages for the average child.

The basis of the JMC's case is that if the present subjects of pure and applied mathematics are condensed into a single subject, the specialist mathematician will suffer. Even if sixth formers were allowed to study mathematics and statistics up to 'Q' level, the statement points out, the specialist mathematician could only devote two-fifths of his time to mathematics during the first year in the sixth form, and only one third in the second year. The JMC believes that so drastic an alteration of the present arrangements, whereby a student can spend two-thirds of his sixth form studies on mathematics, will lower standards in schools and make it necessary to lengthen degree courses.

The JMC believes that the working party which put forward the 'Q' and 'F' level proposals paid too little attention to the numbers of teachers that would be required to carry out its suggestions. Some two to three hundred extra mathematics teachers would be needed, the JMC believes, if further mathematics were to be taught as a separate subject. The council is also worried lest the centralized examinations proposed with the 'Q' and 'F' levels should cause mathematics syllabuses to ossify, and it believes that teachers should have some say in the way that courses are structured.

A way to make sure that the gifted student will not suffer, the council says, is to allow some students to by-pass 'Q' level. This would help to reduce cramming for exams in the sixth form and would help to maintain the standards of 'F' level examinations.

HEALTH

Shutting Up Pandora

Like the Food and Agriculture Organization with its cheerful predictions of long-term food surpluses, the World Health Organization also has some good news to spread, chief of which is that the incidence of smallpox has fallen for the second year in succession to the lowest ever recorded. Another global eradication campaign, that against malaria, has now been extended to some four-fifths of the population in the world's originally malarious areas (*The Work of WHO 1969*. WHO, Geneva, 1970. 14*s*. $2.25).

Less success has been had with plague and cholera which claimed as many victims in 1969 as in the year before. And yellow fever was back in Africa for the first time in six years. In the northern hemisphere, the 1968–69 influenza season started earlier than usual and the A2 strain of the virus, which caused the large outbreak in Hong Kong in 1968, was responsible for numerous epidemics. The upward trend of venereal diseases continued in many countries, though being less marked for syphilis than gonorrhoea, despite the evidence of studies showing that two-thirds of the venereal infections treated by private doctors go unreported.

Parliament in Britain

Atomic Energy Bill

AMONG the legislation which failed to make the statute book before MPs left for their constituencies last week was the Atomic Energy Bill. The bill, which sought to remove the nuclear fuels business and the radioisotopes business from under the wing of the Atomic Energy Authority and to set up separate companies to take care of these activities (see *Nature*, **225**, 1089; 1970), had already been amended and passed by the House of Lords, and was awaiting final approval from the House of Commons. The next government—whatever its political persuasion—must put the bill through the whole parliamentary process for a second time before it can become law.

Defence Contracts

MR JAMES DICKENS asked more questions about contracts for defence research agreed between the universities and the Ministry of Technology. Dr Ernest A. Davies, Joint Parliamentary Secretary to the Ministry of Technology, told him that the ministry's total expenditure on such contracts in the aerospace field in 1968–69 was £1,170,000. The University of Southampton was the biggest single contractor, with contracts worth just over £130,000, the University of London had contracts worth £121,000 and contracts placed at the University of Manchester were worth £111,000. The research involved has both civil and defence applications, Dr Davies said. (Written answers, May 26.)

Research and Development

RESEARCH and development was the subject of several questions from Miss Mervyn Pike. She was told by Mr Edward Short, Secretary of State for Education and Science, that the most recent figures show that in 1961–62, 2·67 per cent of the gross national product was spent on research and development. This had increased to 2·77 per cent in 1966–67 and dropped to 2·73 per cent in 1967–68. Mr Short also said that the total current expenditure on research and development carried out in government departments is estimated to be £229·6 million in 1968–69. This compares with £168·7 million in 1964–65. Mr Anthony Wedgwood Benn, Minister of Technology, also told her that the net cost of running the Ministry of Technology's research establishments is about £21,700 per qualified scientist a year. This figure includes £12,000 in salaries for the scientist and his supporting staff, £6,900 for equipment and £2,800 for buildings. (Written answers, May 27 and May 28.)

Additional University Grants

SUPPLEMENTARY grants to universities, amounting to £20·703 million, were announced by Mr Edward Short in reply to a question from Mr Eddie Griffiths. They will cover the remainder of the quinquennium up to the first four months of the 1972–73 academic year, and are composed of a total of £16·818 million for recurrent expenditure and £3·885 million for capital expenditure. The chief reason for the extra grant is the recent increases in academic staff salaries, which are expected to cost about £8 million a year. (Written answer, May 28.)

Miscellaneous Intelligence

"DEVILS do not occur in cleared places, although they may be found in such areas if there are patches of scrub or high grasses, particularly if large populations inhabit the nearby bush. Devils live successfully in close contact with human settlement and activity, and field observations show that they are most numerous in coastal heath and sclerophyl forest. . . . Man is the principal predator of adult devils" (E. R. Guiler, *Australian Journal of Zoology*, **18**, 49, March 1970).

AFTER a slow start the opposing sides in the battle of the environment are warming up their rhetoric to what promises to be a long, hot summer. Last week the delegate of an American food manufacturing company was complaining to the Society of Chemical Industry in London that the people who want to see all additives banned from food—the organic gardeners, food faddists, and "ecology-minded hippies or econuts"—are often the same as those who would have marihuana made legal. The econuts also have the pesticide manufacturers running scared: "Our industry is frankly disturbed," Mr W. P. Evans, deputy chairman of the British Agrochemicals Association, said recently, "by the present tendency on the part of those who make their own assessments of isolated and imperfectly understood work and promote their individual views to the alarm of the general public. A situation is created in which without any facts or real understanding of the issues, a public pressure for hasty judgment and precipitate action is built up." Mr R. E. Ashworth, chairman of the same association, has also decided the time is right to don a martyr's clothing: "We cannot live in an environment where pesticides are a whipping boy and the cause to champion for every crank. . . . Semi-hysterical emotion is a pollutant that we cannot live with." What sort of emotions can Mr Ashworth have had in mind? Perhaps those of sentiments like that which appeared in a recent editorial in the *Journal of the Soil Association* (**16**, 76; 1970): "Pollution and contamination are the Hitler of today". Hitler versus the econuts: yes, there's no doubt about it, the atmosphere is being polluted.

LIKE those two simple variables on whose changing values couturiers make their fortunes, the hemline and the neckline, the estimates for Britain's population in the year 2000 plunge and rise wildly from year to year. Considering the frivolous way in which the government regards demography—in British universities the subject is chiefly supported by the Ford Foundation—it is not surprising that the government gets the kind of forecasts it deserves. In 1968, for example, it was fashionable to suppose, among the cognoscenti of the Registrar General's Office, that Britain's population of 54 million would add another 21 million to its numbers by the year 2000. Government planners who took any notice of this figure must have been badly caught out when the fashion veered last year to an increase of only 12 million between now and 2000. And last month Mr Crosland was telling a Commons committee that a figure of only 4 million is now the fancied increase for England and Wales (the increase for Britain as a whole, not yet released, is likely to be around 8 million). One thing is as plain as a pikestaff—any talk of a population policy is so much hot air until the government gets itself some decent crystal balls.

NEW WORLD

Scientists against ABM, MIRV, etc.

THREE out of the four ex-Scientific Advisers to Presidents of the United States appeared last week before Senator Albert Gore's Subcommittee on Arms Control, International Law and Organization to complain about the installation of antiballistic missile systems in the United States and about the plan to install multiple warheads on Minuteman missiles from a point later this summer. Although Dr G. B. Kistiakowsky, Dr Jerome B. Wiesner and Dr Donald Hornig have already made their opposition to these developments public, the occasion was outstanding for the eloquence with which they put their case. Most of what they said was also entirely acceptable to the subcommittee except that Senator Gore took less than kindly to Dr Wiesner's suggestion that the subcommittee should put back into its title the word disarmament which had been there until quite recently.

All three speakers were anxious to insist that the SALT talks in Vienna could be jeopardized by a mishandling of the ABM and the MIRV. Dr Hornig, Scientific Adviser to President Johnson, and the incumbent at the White House in 1967 when Mr Robert McNamara argued the case for a limited ABM system with the name Sentinel (not replaced by Safeguard), said last week that "this futile pursuit of actions" tends only to increase the risks of the modern world. "Anyone who surveys the course of the build-up of nuclear armaments in the last 25 years, whether or not it is characterized as a race, can only be struck by the insanity of the result." Like the other speakers at the inquiry, Dr Hornig complained that the United States seems unable to be satisfied with a modest superiority in weapons—the three or four to one advantage over the Soviet Union in the middle 1960s did not bring stability but, rather, an effort by the Soviet Union to install more long range missiles—SS 9, SS 11 and SS 13. One difficulty, he said, was that the arithmetic of superiority is more complicated than mere numbers would suggest. He pointed out that in the past few weeks, Mr Melvin Laird, the Secretary of Defense, has justified new expenditures on weapons by the United States by saying that "our concern is not about today or even next year . . . but about what the future may bring". The only hope, Dr Hornig said, of avoiding continued escalation is if the SALT talks turn out to be successful.

On the Safeguard missile, Dr Hornig argued first of all that it has been assembled from hardware developed for the Nike X system originally intended for the defence of cities and rejected for this use by the present Administration and its predecessor. He said that Safeguard would not do the things expected of it. Even if it performed as it had been designed, however, the number of attacking missiles destroyed would be negligible compared with the cost of the system. He pointed out that the defence of each Minuteman complex would depend on a single radar set costing the best part of $200 million and that this part of the Safeguard system is so vulnerable to attack that a substantial part of the defensive missiles must be devoted to "defending the defense". He went on to argue that the computer system to which the management of an engagement would be entrusted is so complicated that even experienced computer programmers "have no faith that the system would actually work properly when called in, particularly since it would never have undergone full scale tests". For this reason, Dr Hornig concluded, Safeguard cannot be justified as a defence of Minuteman sites. Specifically, "the cost per silo defended would be many times the cost of each Minuteman saved" and would also be greater than the cost of the enemy missiles which could be intercepted with confidence, so that the chief consequence of Safeguard would be to persuade opposing nations to increase the number of attacking missiles.

But is Safeguard necessary as a protection against mainland China ? Since the United States will have overwhelming nuclear superiority over China for years to come, Dr Hornig said the question is "whether the Chinese would choose to commit suicide". For him, the threat of an outright attack by the Chinese on the United States is not to be taken seriously. In any case, he went on, Safeguard could not serve as a reliable protection even against the light Chinese attacks which might be theoretically possible in the late 1970s, partly because it has never been tested, partly because it is in any case a leaky defence, because a puny but prudent attacker would choose targets not yet protected by the early phases of Safeguard, and because even the Chinese would be able, in the late seventies, to confuse the Safeguard radars with extraneous objects.

Dr Hornig echoed the conclusions of his colleagues by saying first of all that he would, if left to himself, abandon Safeguard altogether and would certainly not continue it beyond the first phase of development, but that instead he would put some money into research and development. Similarly, he said, he would delay the deployment of MIRV and put his energy instead into the SALT talks.

Dr Wiesner had some tales to tell of how the United States Administration seems consistently to have overestimated the danger of the weapons in the hands of its potential opponents. He said that "we almost always react from fear—fear of the Russians and in the case of our leaders, fear of our own people", and explained that at the beginning of the Kennedy Administration in 1961, when it was learned that the supposed "missile gap" between the United States and the Soviet Union was more probably in favour of the United States, several people within the Administration (including himself) argued that the time had come to hold down the number of American missiles in the hope that the Soviet Union could be persuaded to do the same. In the end, however, he said, the Administration had agreed to build 950 Minuteman missiles and a force of 41 Polaris submarines. "The explanation given by Secretary McNamara for his recommendation was that because the Air Force recommended 3,000 Minuteman missiles, 950 was the smallest number Congress would settle for." He went on to say that much of the difficulty in arranging for a test ban followed, in his view, from that decision. The parallel with Safeguard and the SALT talks now under way was all too close.

Dr Wiesner also drew attention to the reports now widespread in the United States that construction of SS 9 missiles in the Soviet Union has been tailing off, which means that earlier estimates that there may be 500 of them by the mid-seventies are unlikely to be borne out. But even if there were 500 operational SS 9 missiles, Dr Wiesner argued, a surprise attack on the Minuteman force would leave roughly 270 American missiles intact, not to mention those in submarines and aircraft. "Actually Safeguard looks worse today than it did a year ago to some people—it always looked hopeless to me." It would provide little protection for the US deterrent and in any case such protection is unnecessary.

Inevitably, Senator Gore's interest was aroused by Dr Wiesner's tale of the Minuteman decision and by his statement that "I have seen more proposals for arms control destroyed by the compromises it is necessary to make within the government than by any other cause". He went on to say that in his days at the White House "we used to say that we had four fights on our hands for each new measure of arms control suggested—the Pentagon, Congress, the public and also, I suppose, the Russians". He supposed that Russian negotiators had similar problems, with the result that each delegation would turn up at a conference asking for something unreasonable in the hope of finding out what flexibility the other side would have.

The three Scientific Advisers said that their view of the ABM deployment now under way was shared by the rest of the scientific community. Dr Hornig said he had found a remarkable degree of unanimity and Dr Wiesner went so far as to say that there was very little disagreement with his point of view among the contractors actually building the Safeguard system.

TECHNOLOGY ASSESSMENT

Mr Daddario flies a Kite

A MAJOR threat to the security of the United States is posed by its increasing population, the rapid consumption of natural resources and the deterioration of the environment. Thus argue the advocates of a bill to establish for Congress an Office of Technology Assessment. Hearings on this proposal continued last week before the subcommittee on Science, Research and Development, chaired by Mr E. Q. Daddario, one of the sponsors of the bill.

The OTA would be governed by a board consisting of members of the legislature, seven members of the public appointed by the President, and the Comptroller General and the Director of the Legislative Reference Service of the Library of Congress. The OTA would be under the immediate control of its Director, also a member of the board. Under the bill, the OTA would assess the consequences of technology, present and future, either on request from the chairman of any Congressional committee, the board, or the Director. Its annual budget would be $5 million, which would have to include payments for contracts for assessments to be made by universities or industry when necessary. The advocates of the bill, by no means Luddites, seek a mechanism whereby expert judgment on complex technical issues can be presented to the legislature. The Administration gets advice from several sources but Congress is much less well supplied with information and help, in spite of the valiant work of the Library of Congress in recent years.

The subcommittee's inquiry so far has been thorough, and the witnesses agree that Congress needs the kind of service that Mr Daddario would father on it. But they disagree about the form which such an advisory body should take and even about the credibility of procedures of technological assessment as such.

Dr W. D. McElroy, Director of the National Science Foundation, last week endorsed the need but regretted that the putative Office of Technology Assessment would lack credibility—a great offence in Washington. He argued that technological assessment is so complex that it is virtually impossible to define what is meant by it, and that ignorance prevents a full assessment of the technological consequences of any decision. He said that the technological assessments which had been made so far have been concerned with only first-order effects—the immediate consequences of present decisions. Deeper judgments are harder to come by. If perfection is unattainable, however, imperfect practice is rife. Dr McElroy said last week that several institutions of government are already involved in technological assessment, and he suggested that the proposed office should be a supplement and not a substitute. In particular, he was clearly worried that the creation of the OTA might hinder activities which the National Science Foundation has under way already. He and other witnesses last week emphasized that there are comparatively few people who are able and willing to staff a body such as the OTA.

What are the alternatives? Dr McElroy suggested that the Reference Service of the Library of Congress should shoulder this responsibility, but Mr Daddario briskly retorted that the library has not so far carried out specific investigations and should not do so. Perhaps it would help the OTA, but that is all.

Putting more sand in the works, Dr McElroy also asked whether the OTA would be most useful as a link between the bodies already involved in technological assessment. He was anxious that multiple liaison between a research oriented OTA, institutions of the Administration and the NSF might be confusing. He suggested that in any case much of the required capability is allowed for under existing legislation, and cited as an example the National Environment Act of 1969, which created the Council for Environmental Quality. Dr McElroy also said that the NSF itself already has on hand several projects of technological assessment and is considering whether to establish a unit reporting to the director. The subcommittee may be expected to be duly sympathetic to the plea that the proposed OTA would have the undesirable result of establishing by statute the function of part of the internal organization of the NSF, but there is also the less generous interpretation that the NSF may seek to oppose the creation of another organization which may compete with it for public attention and influence.

Only lukewarm support for the bill came last week from Dr E. Wenk, of the University of Washington, who regarded the bill as inadequate. He suggested that the OTA should be independent not only of the Administration but also of the other branches of government, with a role not merely to advise but also to take decisions on technological matters, if necessary enforcing them in the courts. This clarion call was sharply refuted by the subcommittee. One member observed that, in effect, the head of this body would be an all-powerful technological Ombudsman. Mr Daddario remarked that, if effected, these proposals would be tantamount to the creation of a fourth branch of government, and in discussions with a later witness the subcommittee took the view that such drastic measures would neither be possible under the existing constitution nor, in any case, desirable.

Dr Wenk's vision of the OTA included a staff of some 300–400 with an annual budget in the region of $15 million. This was in sharp contrast with the previous estimate, from Dr McElroy, of 25–30 people, and Mr Daddario had to remind his witness that the bill provides for an annual budget of a mere $5 million, which must include payment for any investigations contracted out. The chairman also remarked that in any case he would doubt the ability of his subcommittee to steer through Congress a more demanding proposal. Although Dr McElroy's estimate is no doubt the more sober, this conflict does draw attention to one drawback of the bill—it is not yet clear just what problems would come under the aegis of the OTA and whether it would in fact have the capability to resolve them.

The subcommittee also dealt last week with the political framework within which the OTA would have to operate, prompted by the testimony of Dr E. Lyons, Chairman of the Department of History at Dartmouth College, and of Dr Dale Wolfle, the retiring Executive Officer of the American Association for the Advancement of Science. The intention of the bill is to strengthen the ability of Congress to exercise a critical faculty on technological issues, and the advocates of the bill argue that there is at present considerable scepticism among the public about the ability of governments to resist the demands of powerful pressure groups. The OTA could help in this respect, as it could also help to stimulate an informed public opinion.

GERONTOLOGY

Public Anxiety about Ageing

THE most recent sign of how exercised Congress has become by the problems of old people is the publication last week of a report of the US Senate Special Committee on Aging. The document is remarkable not merely for its thoroughness but for the way in which its detailed recommendations foreshadow legislation which is likely to transform the condition of old people in the United States. The starting point for the committee's analysis is a carefully documented demonstration of how ageing is increasingly to be equated with impoverishment, deepening with the passage of time. According to statistics compiled by the committee, the median income of families with the head older than 65 was 51 per cent of the median income of younger families in 1961 but only 46 per cent of it in 1967. Three out of ten people aged 65 and older are reckoned to have been living below the poverty line in 1966—in particular, one-quarter of older people living alone had an income of less than $1,000 a year in 1967. One obvious cause of difficulty is that retirement pensions from all sources tend now to amount to between 20 and 40 per cent of average earnings immediately before retirement. The committee calculates that in 1980 roughly half the then married couples will receive less than $3,000 in pension income and it points out that the tendency towards earlier retirement will decrease people's expectations of pension income. Moreover, the committee points out that economic growth, which provides working people with increasing amounts of money to spend, puts pressure on those who have retired while rising medical costs, only partly met by Medicare, will continue to increase.

Among the committee's radical recommendations for dealing with the problem of an ageing population is the suggestion that old people should share in the growth of the economy even though, after retirement, they no longer contribute directly towards it. The committee asks that there should be a social security system providing more liberal benefits than at present, including a widow's benefit equivalent to that to which retired men are entitled, better arrangements for insurance under the Medicare system, an extension of Medicare benefits to deal with prescription drugs for the treatment of chronic diseases, together with a number of reforms of the system (such as the relaxation of the requirement that a person must spend three days in hospital before extended care can begin).

These recommendations are very much in tune with the discussions now widely to be heard of the need for a national health insurance programme in the United States. The Senate Committee on Aging is also concerned with the nutrition of old people, known to be deficient in several well documented ways and not properly taken care of by devices such as the food stamp programme by means of which the indigent are provided with means of buying food cheaply. In much the same spirit, the committee argues the case for the use of urban transit systems in ways that will favour old people and more vigorous attention to the training of older people so as to equip them to stay at work until 65.

The committee complains that in the past year, the funds available for social programmes among old people have been reduced by the curtailment of the Federal budget. The committee is plainly hoping that many of its proposals will have reached the point at which they can be quickly implemented before or soon after the conference planned for 1971—and it is at the same time disconcerted to find that the work done so far in the planning of this conference has fallen short of what it considers necessary.

AIR TRANSPORT

Narrow Shave for the SST

THE project to build a supersonic civil aircraft in the United States narrowly survived defeat in the House of Representatives last week, by 176 to 162. The margin is narrow enough for those who have consistently opposed the project to hope that they will yet be able to bring it to a halt, although the chances are small that they will now be able to deny the Department of Transportation the $290 million in the budget for the coming financial year that has been earmarked for the development of the Boeing aircraft. Their next chance will come when the budget finds its way to the Senate a few weeks from now.

The recent history of the American supersonic transport will seem familiar to those who have followed the Concorde project in detail. Public money was first spent on the project nearly 10 years ago, when Congress authorized $11 million for study of the design. The original intention, fostered by President Kennedy, was that the Federal government should foot 75 per cent of the bill for development and that the total cost should not exceed $1,000 million. After competitive and parallel studies by Boeing and Lockheed, a consortium of Boeing and General Electric was chosen to build the commercial version of the aircraft in 1966. So far, $517 million of public money has been spent on the project, and the sum earmarked for the year ahead will carry the total over the ceiling suggested by President Kennedy in the early sixties.

Opposition to the project has been apparent in Congress for several years, and is now also apparent within the Administration. One of the most vigorous opponents has been Senator William Proxmire, whose economic subcommittee has been collecting evidence against the aircraft for the past five years. Since the beginning of the present Administration, there have been several inquiries into the desirability of continuing support for the project. An inquiry under the auspices of the Under Secretary for Transportation, Mr James Beggs, at the beginning of 1969, was inconclusive, and a review of the documents of that case is now known to have persuaded the President's Science Adviser, Dr Lee DuBridge, to say that he was not in favour of continued support for the project, chiefly on the grounds of public nuisance. A further study in Dr DuBridge's office seems to have confirmed this opinion, but the Administration as a whole decided to go ahead with building the supersonic transport in September last year.

As things are now, the Department of Transportation is the most consistent supporter of the supersonic transport within the administration, chiefly on the grounds that the aircraft will enable the United States aircraft industry to retain its technical leadership. One estimate is that the United States would lose a total of $16 billion by 1990 if other people's supersonic transports turn out to be successful but if the United States has not by then followed suit.

Annual Medallists

THE National Academy of Sciences at its 107th Annual Meeting this week has made the following awards: Dr KLAUS KEIL has been given the George P. Merrill Award for his work on meteorites—he is at present professor of geology and director of the Institute of Meteorites at the University of New Mexico. Dr EDWARD P. HENDERSON has been awarded the J. Lawrence Smith Medal for his lifetime's work for the division of meteorites at the Smithsonian Institution—he retired in 1966. DR EARL R. STADTMAN receives the academy's Award in Microbiology for his work on enzyme control mechanisms at the National Heart Institute. DR A. DALE KAISER has been awarded the US Steel Foundation Award in Molecular Biology for his work at Stanford University on the replication of virus DNA in infected cells. DR RAYMOND C. MOORE, of the University of Kansas, receives the Mary Clark Thompson Gold Medal for his work in editing the monumental *Treatise on Invertebrate Palaeontology*. DR THOMAS FRANCIS, professor of epidemiology at the University of Michigan until his death last October, was posthumously awarded the Jesse Stevenson Kovalenko Gold Medal for his involvement with the introduction of vaccines against virus diseases, particularly the Salk polio vaccine in 1954 and the influenza vaccine in the late sixties.

NATIONAL SCIENCE BOARD

Chairman for Science Board

THE National Science Board, the governing body of the National Science Foundation, last week elected as chairman for the next four years Dr H. E. Carter, Vice-Chancellor of the University of Illinois. Dr Carter will succeed Dr Phillip Handler, who became President of the National Academy of Sciences a year ago. Dr Handler remains a member of the National Science Board, but the election will remove the anomaly in which Dr Handler has been chairman of what is essentially a government agency, autonomous though it may like to think itself, and also president of the National Academy of Sciences and potentially a critic of government policy. Although this arrangement seems not to have prevented Dr Handler from speaking out on important issues, especially in the past few months on the reduction of the budget for university research, it has been plain even to his admirers that the arrangement could not continue indefinitely.

The appointment of Dr Carter will be watched for signs of whether he will be able to develop within the National Science Board the apparatus for appraising the development of public policy towards science and technology which has been thrust on the board in the past two years.

NEWS AND VIEWS

In Pursuit of the *Y* Chromosome

A FEVER of excitement among cytogeneticists is being whipped up by a chemical used to treat malaria. The chemical, quinacrine dihydrochloride, has a remarkable and as yet unexplained propensity for staining the stem end of the *Y* chromosome. It has already been used to spot the *Y* chromosome in human interphase cells and now the same has been done for spermatozoa. The technique will certainly afford a useful test of success to those who are trying to separate male and female determining sperm as a means of sex control. But the more immediate results will be in solving straightforward cytogenetic problems as well as in clinical medicine and genetic counselling. Moreover, it seems that not only does quinacrine mark others besides the *Y* chromosome but also that a whole range of different specificities may lie waiting to be discovered among other fluorochrome chemicals, particularly those based on the acridine ring. At the least the new technique will hasten the rate of progress in human cytogenetics and with any luck the next five years should see a number of fresh insights opened into the behaviour of chromosomes in cells.

The story began with the work of T. Caspersson and his colleagues who showed some two years ago that certain fluorescent derivatives of acridine stain the chromosomes of various organisms. Last year one of Caspersson's colleagues, Laura Zech, noticed that quinacrine mustard makes part of the human *Y* chromosome fluoresce particularly brightly. This illuminating finding has been taken up in several laboratories and important discoveries seem to be emerging rather faster than they can appear in print. Two months ago, for example, P. L. Pearson, M. Bobrow and C. G. Vosa demonstrated that the quinacrine staining test shows up the number of *Y* chromosomes in a human interphase (non-dividing) cell. This is an important time saver for those engaged in screening human populations for *XYY* males, the possessors of an extra *Y* chromosome who tend, as adults, to be found in prisons slightly more often than it seems they should be. Hitherto the only way of identifying the extra *Y* chromosome has been the laborious task of culturing leucocytes and doing a full karyotypic analysis. The quinacrine test is the exact counterpart of the simple stain for the Barr body which shows up the presence of extra *X* chromosomes and led indirectly to the discovery of *XYY* males in the first place.

The next two apples to fall from the tree are displayed in this issue (pages 959 and 961). Pearson and Bobrow have used the quinacrine technique to settle the admittedly somewhat academic issue, though one of thirty years' standing, as to whether it is the short arms or the stem of the *Y* chromosome that is associated with the *X* chromosome in meiosis; the answer is the short arm.

Peter Barlow and C. G. Vosa have used the stain on human spermatozoa with the result that they have distinguished, as many geneticists have dreamed of doing, the male determining spermatozoa from the female ones. Admittedly this will not lead tomorrow to methods of sex control, if only because the dye almost certainly kills as it distinguishes. But in any case the quinacrine stain, or others like it, should provide a simple test for assessing the various methods, whether based on centrifugation or electrophoresis, whereby people have sought to separate the two kinds of sperm. In the past the outcome of such methods has been uncertain because it could only be tested by breeding.

Animal breeders should hold their enthusiasm for a little while yet. Dr Barlow has said on the telephone that quinacrine now appears not to distinguish the *Y* chromosomes of bull spermatozoa since it stains all the chromosomes equally. It may be that man is unique among the mammals in this respect. But even if quinacrine is selective only in man, its use in this species is not restricted to the *Y* chromosome. Dr Pearson and his colleagues at Oxford have found that certain of the autosomes take up the stain in a way that depends on the individual. The acridine dyes certainly hold a lot of interesting secrets in store and in the coming months laboratories throughout the world will doubtless be fluorescing with excitement to find out just what these may be.

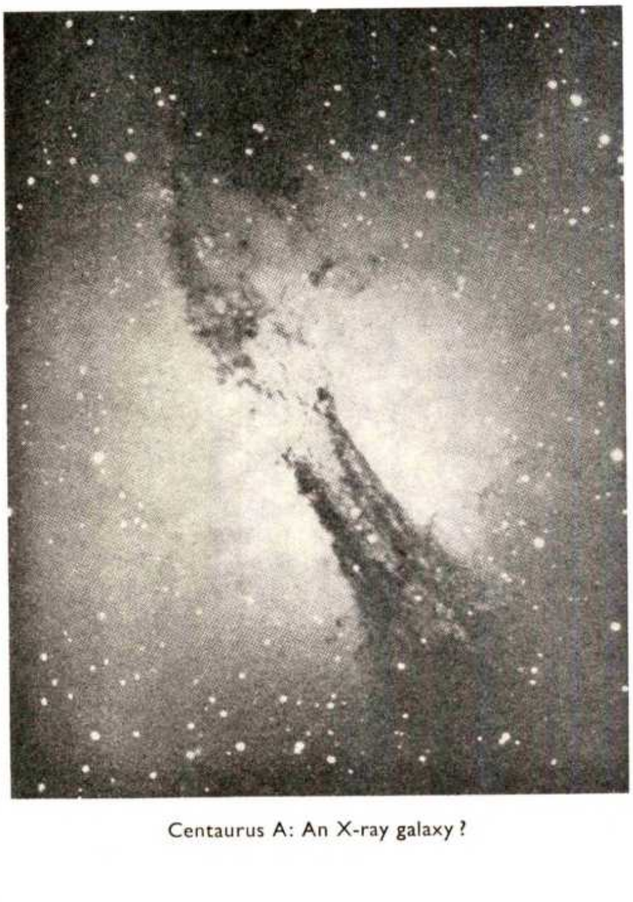
Another X-ray Galaxy ?

THE detection of X-rays from the radio galaxy Centaurus A by C. S. Bowyer's group at the University of California, Berkeley, brings to three the number of extragalactic objects with associated X-ray emission. There are, of course, thirty odd X-ray sources known to be probably within the Milky Way galaxy, of which the strongest appears to be Scorpius X-1. But Centaurus A at a distance of twelve million light years seems to be intrinsically of the order of 10^5 times more powerful than Sco X-1. With the result of Bowyer, M. L. Lampton and J. E. Mack indicating that the X-ray emission from the radio galaxy Centaurus A is approximately twice the radio emission, it seems that Centaurus A, one of the brightest objects in the radio sky, ought more properly to be called an X-ray galaxy.

Its peculiar appearance at optical wavelengths as much as anything has been the stimulus to observe Centaurus A with X-ray equipment, but so far the results have been inconclusive. The California telescope flown on an Aerobee rocket from Natal, Brazil, last summer measured a flux of 0·04 photons cm^{-2} s^{-1} making the X-ray emission from Centaurus A roughly a third of that from the X-ray galaxy M87. The third extragalactic X-ray object is the quasar 3C273, and all three were detected during the flight. Clearly the sensitivity of the California telescope coupled to the technique of concentrating on just three sources rather than allowing the telescope to scan across the sky tipped the balance in favour of the detection of Centaurus A.

The optical characteristic of Centaurus A is the dark lane running across the galaxy, but at radio wavelengths the pattern is the familiar one of a double radio source about three million light years across with the optical galaxy at the centre. In the case of Centaurus A, however, the optical galaxy marks the midpoint of a second double radio source which is much nearer the optical object. From the current dogma of exploding galaxies the inference is that Centaurus A must have exploded twice.

Another stimulus behind the search for extragalactic X-ray objects is to see whether sources outside the Milky Way can account for the isotropic X-ray background. This would require galaxies to emit something like 10^2 to 10^3 more energy in X-rays than at longer wavelengths. But with the ratio being more like fifty for M87 and about unity for Centaurus A this hypothesis now looks less probable than the alternative based on Compton interactions between cosmic ray electrons and the microwave background.



Centaurus A: An X-ray galaxy ?

SINGULARITIES

How to Spot a Black Hole

from our Cosmology Correspondent

INTEREST in the existence of "black holes" of collapsed matter, which was recently stimulated by Lynden-Bell's suggestion that such holes could be associated with quasars and galaxy centres, will receive a further boost as a result of the relative ease of some observational tests which have now been proposed by A. A. Wyller (*Astrophys. J.*, **160**, 443; 1970). Wyller is particularly concerned with the possible existence of black holes in globular clusters, where they may be responsible for the brightness excesses observed at the cluster centres. Postulating that a supermassive object has collapsed into a singularity in such a cluster, Wyller examines in detail spectroscopic and gravitational tests for such an object; these are marginally possible with present-day techniques, so that there is every chance of a positive result being achieved as future developments make observations easier.

The holes considered have masses comparable to a few per cent of average globular cluster masses, which are themselves $\sim 10^5$ $M_\odot$, so that their radii are in the range 0·01–1·0 $R_\odot$. For the particular case of 47 Tuc, where the spectroscopic possibilities are best, as a result of the cluster's large size and proximity to the solar system, an analysing diaphragm of 2″ would give a sampling radius of 10^6 $R_\odot$ about the hypothetical black hole, in which range it should be possible to detect the contribution of orbital Doppler shifts in the spectra of the stars close to the central singularity in the line spectra. Measurement of a gravitational redshift would be more difficult, but this might prove detectable as a steady component while the Doppler component varies cyclically over a few years. Wyllers' calculations suggest that the steep density gradient inside a globular cluster ensures that, for 47 Tuc at least, contributions to the total line profile in the line of sight from stars perturbed by the black hole and those unaffected by it should be roughly comparable.

The technological advances utilized by Weber in his search for gravitational radiation make this a plausible alternative means to observe black holes. With two revolving black holes at the centre of a globular cluster, Wyller shows that the rate of gravitational radiation can be much higher than that expected from other phenomena, both in the Earth mode frequency (1 cycle per hour) and higher frequencies up to ~1 cycle per second. Again treating 47 Tuc in detail, he predicts a flux at the Earth of $3\cdot7\times10^5$ erg cm^{-2} s^{-1}, compared with 3×10^{-5} erg cm^{-2} s^{-1} for the flux from a white dwarf pair rotating every 100 s at a distance of 100 pc from the Earth. Even more pronounced effects might arise from the galaxy centre type of black hole discussed by Lynden-Bell and others.

Ap STARS

Anomalous through Diffusion

from our Observatories Correspondent

THE suggestion that the composition anomalies in the spectra of Ap stars have resulted from diffusion in the surface layers will be greeted with interest by students of these peculiar stars (G. Michaud, *Astrophys. J.*, **160**, 641; 1970). Ap stars are characterized by abnormally strong lines of certain elements, particularly silicon, manganese, chromium, strontium and the rare earths, while other elements—notably helium, oxygen and carbon—have abnormally weak lines. Known for sixty years, Ap stars constitute about twenty per cent of all main sequence stars with effective surface temperatures between about 8,000 K and 20,000 K, and are only found in this range. There is, however, no widely accepted theoretical understanding of their properties.

In the early 1950s, H. W. Babcock found that Ap stars had large surface magnetic fields, typically between 1 and 10 kgauss, and as high as 34 kgauss in one case. He found that the fields often varied, on a time scale ranging from days to years. Later work by Babcock and G. W. Preston produced evidence that the variations are periodic, that the period is the rotation period of the star and that the axis of the magnetic field (usually not a simple dipole) is inclined to the rotation axis. Other variations in the spectra of Ap stars have led to the idea of localized patches of abnormal composition on their surfaces.

The anomalies in composition are very pronounced and during the past fifteen years spectroscopic analyses have demonstrated correlations between the behaviour of certain elements. For example, in some Ap stars the rare earth elements are overabundant by factors of about 10,000, while oxygen is deficient by a factor of about 100. There is also evidence that the character of the abnormal compositions is related to the surface temperature. For example, stars characterized by an abnormally high abundance of Mn are only found with surface temperatures of about 12,000 K.

Suggesting that the composition anomalies in the spectra of Ap stars have resulted from diffusion in the surface layers, Michaud adopts the view that the large magnetic fields, the origin of which he does not consider, stably stratify the outer layer against mass motions such as convection. (An effect of this kind can be seen in sunspots where the magnetic fields damp down the solar granulation pattern.)

Hydrogen provides the bulk of the material in a stellar atmosphere. In a stably stratified atmosphere heavier elements diffuse downward under the gravitational field of the star. Michaud shows that the time scale for this gravitational settling is only 10^4 years, much less than the 10^8 years which the star spends in the main sequence. The tendency to sink is opposed by radiation pressure, however. This may act at the discrete frequencies of spectral absorption lines or in the photoionization continuum of any particular element. Whether or not the levitation due to radiation pressure wins over the gravitational settling depends on the temperature of the star and the details of the atomic spectrum of a particular ion. Thus an element may sink at one temperature when it is neutral and be pushed up at another temperature at which it is ionized.

Michaud has calculated the expected behaviour of several elements as a function of temperature, and found in many cases a satisfactory agreement with observation. In particular, he explains why stars with an excess of Mn are found with surface temperatures of about 12,000 K. But Michaud's diffusion mechanism may not be the full story. Spectroscopists have found lines of very heavy elements—mercury, platinum, osmium and perhaps even uranium—in some Ap stars, and there is evidence that the isotopic compositions of some of these elements are abnormal, in the sense that the neutron-rich isotopes are overabundant compared with terrestrial samples. This could not be attributed to atomic diffusion and would point to a nuclear origin for the composition anomalies of Ap stars. Specific nuclear theories, proposed by Hoyle, Fowler and the Burbidges, had some unsatisfactory features but no doubt the whole situation will be reassessed in the light of these new developments.

OCEANS

New Crustal Layer

from our Geomagnetism Correspondent

IT is generally accepted that the lowest layer of the Earth's oceanic crust, immediately above the Mohorovičić discontinuity, has a seismic velocity of about 6·8 km s^{-1}. This is the crustal layer with the highest velocity, and contrasts with the uppermost layer of the mantle which has a velocity greater than 8·0 km s^{-1}. Velocities between these figures are not unknown; a layer of seismic velocity 7·0–7·5 km s^{-1} is a feature of mid-oceanic ridges, some ocean margin regions and certain trenches, but velocities in this range have not been regarded as typical of ocean basin structure.

It now looks as if this view must be amended. Maynard (*Science*, **168**, 120; 1970) has produced unequivocal evidence that a basal crustal layer with velocities in the range 6·9–7·6 km s^{-1} (average, 7·3 km s^{-1}) exists below the Pacific Ocean in the region between the Marshall and Hawaiian Islands. Refraction seismology leaves no doubt that the new layer exists in this region—and its extent (1,000 km) and thickness (several kilometres) suggest that it is probably widespread throughout the South and Central Pacific.

But why has it been missed for so long ? One reason apparently is that the new intermediate layer is normally masked as a second arrival. Maynard overcame this problem by using an air cannon as a repetitive signal source in conjunction with sonobuoys and precision echo sounder recorders. The repetitive signal resulted in an extremely high density of data; and the recorders were arranged for phase correlations. This revealed refraction arrivals which are usually not recognized, either because they never appear as first arrivals at all or because they appear only in the form of short segments of first arrivals at a distance where data from explosive sources are widely spaced.

Further evidence for a wide geographical coverage of the new layer comes from refraction experiments carried out since Maynard's pioneering work. D. M. Hussong and his colleagues, for example, are known to have found the same layer in the deep ocean north of Hawaii and 180 km west of San Francisco, although full details have not been published. If the layer is widespread, however, the implications are interesting. For one thing, it would mean that there is a widespread change in composition or a polymorphic transition at the interface between the two lowest crustal layers. This would imply that the mean density of the Earth's crust must be higher than previously supposed—an adjustment which would affect depths determined from gravity anomalies and possibly even density distributions consistent with the Earth's moment of inertia.

METEOROLOGY

Droughts and Fires

from our Geomagnetism Correspondent

EVERY schoolboy knows that droughts are liable to result in vegetation fires. What is less obvious is that the fires themselves contribute to the drought, especially in tropical and sub-tropical climates. The reason for this is that the tropical cumulus clouds, in common with all clouds, require nuclei to condense on before rain can fall. When such condensation occurs raindrops begin to form on nuclei ranging from 0·1 to 1 μm in diameter but must grow to about 400 μm before they fall to Earth. If a large excess of nuclei is present, each nucleus will compete for the available water, and there is a real possibility that none will reach the critical size.

Burning vegetation produces many small particles, all potential cloud nuclei. Just how many particles are formed has been the subject of an investigation of the 1967 drought in Florida by Ronald J. Holle of the Experimental Meteorology Laboratory (ESSA) in Miami. During the drought from April 1 to May 15, at least 52,000 acres of vegetation burned within 115 miles of Miami. The frequency of fires was substantially higher than usual, but rainfall was observed only twice in the 46 days of drought—an extremely low total of only 0·15 to 0·30 inch which fell only on non-fire days.

What, then, did the fires contribute to this situation ? There are five major types of natural vegetation in Florida. Some 3,500 square miles are covered by everglades marshes, much of which is only saw grass although some areas have herbs, bushes, tree islands and sloughs as well. The surface is normally flooded with algae covering as much as 50 per cent of the water to a depth of about an inch. When a drought comes the water table lowers and the dry, combustible algae cling to the saw grass. Another 3,300 square miles are pine forest—open woodland lying partly on rock and intermingled with herbs, saw palmettos, shrubs, other hardwoods, tropical hummocks, cypress swamps, prairies and bay tree swamps. Grassland covers 850 square miles, open scrub cypress a further 660 square miles, and wet to dry prairie marshes make up 1,450 square miles.

Holle collected samples of each of these types of vegetation, burned them in controlled laboratory conditions and measured the cloud condensation nuclei produced. The materials burned were in a closed chamber in conditions simulating both open burning with abundant oxygen and confined burning resulting in slow combustion or smouldering. Each gram of vegetation burned produced between one billion (10^9) and ten billion condensation nuclei ! Slow burning produced about twice as many nuclei as fast burning, and algae, a major fuel in fires during periods of drought, produced twice as many nuclei as any other component. Holle is thus justified in his conclusion that fires can reduce rainfall from large cumuli and substantially reduce the rain falling from smaller clouds in the immediate vicinity of the fires.

It is therefore instructive to speculate on the effect of man-made fires. Jamaica, for example, suffers from droughts which may well be aggravated by the burning of cane fields. Cane fields are also burned in south Florida between November and April. In 1968, 168,000 acres of cane were burned in Palm Beach County alone. Whether fires on such a massive scale can actually produce a drought is still an open question; but certainly fires which occur during a drought can prolong the dry period.

PARTICLES

Cutting Tachyons down to Size

ONE of the loose ends of special relativity that has been achieving some attention in recent years is the idea that particles that travel faster than light cannot be ruled out by the special theory of relativity. Since the suggestion was first sported in 1962 there have been several attempts to contrive evidence to support it. A new clue as to why such faster-than-light particles, called tachyons, may be hard to find if they are not indeed a mathematical figment has come from an unexpected corner of physics, namely a model of a dislocation.

S. I. Ben-Abraham (*Phys. Rev. Lett.*, **24**, 1245; 1970) has drawn attention to the analogy between a model of dislocations developed by Frenkel and Kontorova and the theory of relativity. In this model the atoms move under harmonic forces between neighbours and a sinusoidal interaction with a rigid substrate, giving solutions which have been found to include supersonic excitations called positive and negative antidislocations. He sees the propagation speed along a chain of atoms—the velocity of sound—playing the role of the velocity of light and the supersonic solutions as being analogous to the tachyons attributed to relativity theory. A so-called tachydislocation is then described by a chain of atoms most of which sit on potential crests.

Ben-Abraham points out that at moderately supersonic speeds such excitations are highly unstable and have not been observed. The concentration of energy in such an excitation would give the appearance of a massive object in the solid, and in one dimension a boundary would exist dividing regions of subsonic and supersonic space. Ben-Abraham suggests therefore that as tachyons could only exist in regions inaccessible to normal subsonic particles this provides an indication that they are unlikely to occur in practice.

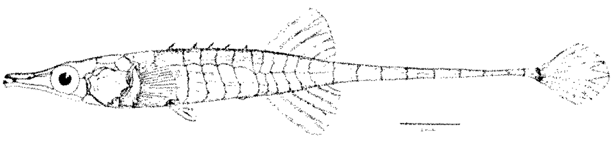
SYSTEMATICS

Paradox may be Solved

from our Marine Vertebrates Correspondent

SYSTEMATIC ichthyologists have made fine play with the relationships of the seahorses, pipefishes and their allies, and the sticklebacks. These creatures have been placed at almost opposite ends of the teleost classification, brought together, and then united in one order. One of the gems that confirmed the unitarians in their belief in a single order was the discovery in Lake Indawgyi, Burma, in 1926, of an enigmatic small fish later to be named *Indostomus paradoxus*. This seemed to bridge the two groups, as a stickleback-like pipefish with the long snout and body armour of the pipefishes, and a series of isolated spines along its back as in the sticklebacks. Now a study by K. E. Banister (*Bull. Brit. Mus.* (*Nat. Hist.*) *Zool.*, **19**, No. 5, 179; 1970) suggests that these resemblances are purely superficial and *Indostomus* is not related to either group.

Originally *Indostomus* was placed in the pipefish order Solenichthyes by its discoverers Prashad and Mukerji (*Rec. Indian Mus.*, **31**, 161; 1929), and Bolin later confirmed this (*J. Wash. Acad. Sci.*, **26**, No. 10, 420; 1936), although differing in his assessment of relationship within the family. Berg's classification of fishes lumped *Indostomus* in with his pipefish order Syngnathiformes, but more recently Greenwood *et al.* (*Bull Amer. Mus. Nat. Hist.*, **131**, No. 4, 339; 1966) placed it in a holdall order of Gasterosteiformes. The basic difficulty with *Indostomus* was two-fold: first, its anatomy had never been properly studied or described, and second, because it was a highly modified fish its systematic position was unclear.



Indostomus paradoxus.

The first of these difficulties has now been overcome with Banister's detailed examination of the skeleton. He finds fifteen major features in which *Indostomus* differs from the sticklebacks and their most primitive family the Aulorhynchidae, while the external body armour and pronounced snout are only superficial resemblances to the pipefishes. Banister's conclusion on the second point is that this curious little fish is sufficiently distinct to be placed in a new order Indostiformes, of which it is the sole member. The position of this order within the fish system, however, seems to be if not a paradox then as enigmatic as ever, and a tentative situation near the clingfish order Gobiesociformes is proposed.

But what of the fish itself? Banister's report concludes with a fascinating account of this peaceful little fish by Alan Tubb of the UN Food and Agriculture Organization in Thailand, who collected 140 specimens and kept them alive in aquaria. From these notes (the first on the behaviour or biology of the species) *Indostomus* can be seen as quiet, peaceful and generally slow-moving, although it can be swift when alarmed. It feeds entirely on living animal food, slowly stalking its prey with fins depressed, except for the fluttering of its pectoral fins. In spite of its seemingly rigid body armour *Indostomus* is remarkably flexible and seems to be able to move its head at an angle of some 10° to the body in all directions, an unusual accomplishment in a fish. Evidently *Indostomus* is a fish well endowed with surprises for the ichthyologist.

EMBRYOLOGY

Very Early Mammals

from a Correspondent

THE successful manipulation of the mouse blastocyst provided the topic for one of the most impressive contributions to the Schering symposium on intrinsic and extrinsic factors in mammalian development, held in Venice from April 20 to 24. Dr R. L. Gardner (University of Cambridge) reported that microsurgical techniques can be used to separate the trophoblast from the inner cell mass (ICM), and that the two components are markedly different in their behaviour and growth potential after transfer to the uteri of pseudo-pregnant recipients. Thus, grafts of trophoblast alone can induce decidualization, but otherwise fail to proliferate. By contrast, fragments of ICM develop within the host and produce normal young; pairs of such ICMs can be fused *in vitro*, even when their ages differ by twenty-four hours. Blastocysts and mere trophoblastic envelopes can also serve as carriers of an ICM of a different genotype, with subsequent mixing of their cells and formation of viable chimaeras. Such blastocysts "reconstituted" after *in vitro* manipulation provide a powerful new system for examining the diverse interrelations of trophoblast, foetus and the maternal environment. Gardner's results also suggest that the number of cells from which the embryo proper develops may be remarkably small.

The extraordinary resilience and ability to fuse of cleaving mouse eggs were demonstrated on film by Professor J. G. Mulnard (Brussels), while Dr W. K. Whitten (Bar Harbor) reported his highly successful technique for culturing pre-implantation embryos in an exactly defined chemical medium, with a high yield of normal mice following transfer to the uteri of pseudo-pregnant hosts.

Dr T. G. Baker (University of Edinburgh) provided convincing ultrastructural proof that the mammalian oocyte in the prolonged diplotene stage of meiotic prophase is not, as too often assumed, resting, but synthesizes ribonucleoprotein and actively contributes to the growth of the surrounding follicle.

The importance of the biochemical milieu encountered by the pre-implantation blastocyst was stressed by Drs H. M. Beier (Marburg, Germany) and J. C. Daniel (Colorado). They have shown that during this phase the intrauterine fluid in the rabbit has a high protein content, partly derived from the maternal plasma and partly from the endometrium itself. Among the specific fractions is a glycoprotein ("uteroglobin" or "blastokinin") which is present in intrauterine and blastocoelic fluid and may promote embryonic growth. No comparable fraction has so far been isolated from human uterine secretions.

The complex system of cellular interactions between the first stage of "induction" and the fully differentiated tissue may soon come into closer focus. This was the implication in the contribution from Professor H. Tiedemann (Berlin) who described the isolation of a protein fraction from chicken embryo which can induce the formation of endoderm and mesoderm in amphibians, but which is counterbalanced by an inhibitor, an acidic protein. The study suggests that transcription of RNA is involved in differentiation and that hormones may take part in the later morphogenetic stages.

PROTEINS

Primordial Muscle

from our Molecular Biology Correspondent

THE presence of contractile protein systems in such nondescript objects as amoebae and slime moulds, not to say in fibroblasts and leucocytes, is now well established. In several cases actin-like and myosin-like proteins have been dredged from the cytoplasm, and it has been conjectured that something very akin to muscular contraction may underlie the process of cytoplasmic streaming, which is the basis of the lethargic locomotion of which these organisms are capable.

The properties of the myosin from a slime mould, previously isolated by Hatano and his colleagues, have been studied recently by Hatano and Ohnuma (*Biochim. Biophys. Acta*, **205**, 110; 1970). In agreement with Adelman and Taylor (*Biochemistry*, **8**, 4976; 1969), they find that the protein has a sedimentation coefficient little different from that of rabbit muscle myosin. The viscosity, however, though high, is considerably less than that of muscle myosin, and it is inferred that the presumed rod-like part of the molecule is either shorter or more flexible. The most distinctive difference between the two proteins, as Adelman and Taylor also noted, is that when the salt concentration is reduced no filaments are formed; instead some low aggregates, up to perhaps the tetramer, can be discerned in the ultracentrifuge. The amino-acid compositions are very similar, with the notable exception that cysteine, of which there are enzymatically vital residues in rabbit myosin, is absent in the slime mould protein. The ATPase activities, according to Hatano and Ohnuma, are comparable, but Adelman and Taylor find three times higher activity in the slime mould enzyme. There is also disagreement about the effect of magnesium, which Hatano and Ohnuma say inhibits the ATPase, but which Adelman and Taylor say does not.

The broad parallel between the actomyosin of vertebrate muscle and the putative contractile system of the slime mould has been placed on a much surer footing by two new studies with the electron microscope. Nachmias, Huxley and Kessler (*J. Mol. Biol.*, **50**, 83; 1970) have shown that the actomyosin of this creature occurs as long filaments, some 50 Å thick, looking very like actin, and bearing at intervals formations of the characteristic arrowhead shape seen in mixtures of authentic F-actin and myosin. There are also thin fibres, joining the filaments at irregular intervals. When ATP was added all the attached bodies were released, leaving isolated filaments with the beaded structure of actin. Preparations of the actin-like protein had a thickness of 40–50 Å, which is less than that in muscle actin, and a 360 Å periodicity. The most striking feature of this work is the appearance of indubitable, though somewhat irregular, arrowhead structures on addition of rabbit myosin subfragment-1 (the isolated globular heads). That the slime mould actin reacts with mammalian myosin was inferred some time ago, but the present results show that the mode of interaction is the same as in muscle, and that the binding sites of the actin—both for myosin and for its own neighbours—have been conserved throughout evolution.

A parallel study, this time on an amoeba, accompanies this paper (Pollard *et al.*, *ibid.*, 91). The actin again appears as beaded filaments, some 60 Å in diameter, and in some of the pictures the twisted double helical structure can be made out, with a period of 370 Å. When the actin was mixed with rabbit heavy meromyosin (myosin with a proteolytically truncated shaft), good regular arrowheads were seen at intervals of 370 Å along the filament. A similar appearance is presented by the filaments of the intact cell on addition of heavy meromyosin, these measuring moreover about 80 Å across, just like the thin filaments of rabbit muscle. It thus seems that in spite of some obvious differences in the myosins, the mechanochemistry of these primitive cells is indeed closely related to that of muscle, and that different systems of motion evolved from a common precursor.

NITROGEN FIXATION

Proteins and Associations

from a Correspondent

ANOTHER step forward in the understanding of biological nitrogen fixation has been the recent isolation of the second protein associated with nitrogenase, the enzyme complex involved in this process. Nitrogenase consists of two protein components, no matter from what organism it is isolated. L. E. Mortenson's team at Purdue University obtained the first almost homogenous preparation of one of these—the oxygen-sensitive, non-haem iron protein from *Clostridium pasteurianum*—90 to 95 per cent pure. It had a molecular weight of 40,000 and contained two iron atoms and two labile sulphur atoms per molecule (*Biochim. Biophys. Acta*, **172**, 106; 1969). The second protein associated with nitrogenase is not particularly oxygen-sensitive; it has been known for some years to contain molybdenum as well as iron and labile sulphur, but it has been difficult to purify because of its disposition to aggregate and disaggregate. A significant advance has been made, according to preliminary reports, by R. W. F. Hardy's group at Dupont de Nemours, Wilmington, Delaware (*Biochim. Biophys. Res. Commun.*, **39**, 90; 1970).

They have obtained crystals of the Mo–Fe protein from *Azotobacter vinelandii* as needles which appear when the ionic strength of the solution is lowered. This is an unusual procedure for crystallizing proteins: high ionic strengths, or at least lowered water activities, tend to be favoured among practitioners of the art (which tends to have culinary as much as scientific overtones). The Dupont group's product has one or two peculiar properties: although the solution is intensely brown, the crystals are white. The molecular weight exceeds all earlier claims, being nearly 300,000, and the crystals contain approximately two Mo atoms, forty Fe atoms, forty cysteine residues and thirty labile sulphur atoms. Though crystallinity is not, among proteins, an absolute criterion of molecular homogeneity, the prospect of authentic crystals of one of the components of nitrogenase opens exciting vistas for structural studies.

On the more biological front, the use of the acetylene reduction technique continues to revolutionize ideas about the distribution of nitrogen-fixing organisms. Several groups of microorganisms which were believed to be able to fix nitrogen have now been struck off the list; hitherto unsuspected ones are being discovered in strange environments. Perhaps the strangest case was described by F. J. Bergersen and E. H. Hipsley of the CSIRO Division of Plant Industry, Canberra (*J. Gen. Microbiol.*, **60**, 61; 1970), who found nitrogen-fixing bacteria of the *Klebsiella* group in the intestines of pigs, guinea-pigs and humans. Among the humans were not only Europeans from Canberra, but also natives from the Morobe district in the Territory of Papua–New Guinea; natives who live on a very low nitrogen diet, based principally on sweet potatoes. These observations raise once more the idea, never completely dismissed, that nitrogen-fixing bacteria can contribute to the nutritional status of animals, including man, when the dietary nitrogen is low. Bergersen and Hipsley showed that a guinea-pig which had been fed a diet low in nitrogen for several days reduced acetylene, slowly but definitely, when exposed to this gas in an enclosed chamber. This experiment shows that the nitrogen-fixing bacteria in its intestines were actually active, though their relevance to its nutrition is still an open question. All the well established nitrogen-fixing associations have been between bacteria and plants, and the leguminous association, which is perhaps the best known, has been peculiar because neither the plant nor the microorganism can be persuaded to fix nitrogen separately. At the April meeting of the American Society for Microbiology, Hardy's group reported use of the acetylene reduction technique to demonstrate fixation *in vitro* by microorganisms growing with isolated plant cells. Rapidly dividing cultures of root cells from soya bean were inoculated with *Rhizobium japonicum*; an association was formed which could be observed by electron microscopy and which reduced acetylene at about 1 per cent of the rate found with intact soya bean root nodules. As Hardy and his colleagues recognize, these experiments open, for the first time, the prospect of studying the effects of plant hormones on this curiously obligatory symbiosis.

PERCEPTION

Detectors in Human Visual System

from our Neurophysiology Correspondent

EVIDENCE has recently been published for the existence of orientation and size detectors in the human visual system (Campbell and Maffei, *J. Physiol.*, **207**, 635; 1970). This gives firm support to the possibility of linking neurophysiological and psychophysical data.

Campbell and Maffei showed their subjects gratings on an oscilloscope face. These were fields with brightness sinusoidally modulated spatially, giving the appearance of fuzzy, alternating light and dark bars. Previous experiments had established psychophysical thresholds for seeing a grating at various contrast levels and spatial frequencies (discussed in *Nature*, **224**, 311; 1969). The psychophysical threshold was defined as that contrast level at which the subject could correctly report the orientation of the grating, which implied that he could clearly distinguish it from a uniformly bright field of the same mean luminance. To obtain a neurophysiological measure Campbell and Maffei presented the gratings as before, but reversed their contrast eight times a second. They recorded the evoked potential to this stimulus between two scalp electrodes above the visual cortex. The evoked potential was filtered so that its power at eight cycles, the stimulus frequency, could be measured. Each experimental datum was therefore an evoked potential amplitude for a grating of particular spatial frequency at a given contrast level. To obtain a measurable evoked potential amplitude it was necessary to average the response to several hundred presentations, improving the signal-to-noise ratio. This limited the experiment to stimuli well above threshold contrast as the nearer the threshold the longer the averaging time needed for a measurable amplitude.

Their results show that amplitude is linearly related to log contrast, as would be expected if Weber's law applied. (Weber's law states that the least discriminable stimulus increment is a linear function of background stimulus intensity.) Further, linear extrapolation to zero amplitude gives a value of contrast agreeing well with the psychophysically measured contrast thresholds at all spatial frequencies used.

This technique was also used to investigate the effect of adapting the retina to one grating on the visibility of a second. There was no decrement in visibility if a grating of the same spatial frequency as the adapting grating was presented in an orientation such that its axis was at least 15° from the axis of the adapting grating. With orientation differences between 0° and 15° there was an approximately linear increase in the amplitude of the evoked potential of the second (test) grating. Similarly, gratings of the same orientation but at least one octave apart in spatial frequency showed no decrement in visibility. Reducing the frequency produced an increasing interaction leading to a decrease in the visibility of the test grating.

Campbell and Maffei have thus given clear evidence of many channels sensitive to frequency and orientation, which are largely independent. Subsidiary results show that the foveal and extra-foveal distributions of these are different. Where relevant psychophysical data are available they agree with data from these experiments.

Three Hundred Years of Botany in Edinburgh

by
J. A. RATTER
Royal Botanic Garden,
Edinburgh, 3

This week the tercentenary of the Royal Botanic Garden, Edinburgh, is being celebrated with, among other things, the opening of an exhibition hall given by an anonymous donor. This article traces the fortunes of the Garden during the past three hundred years.

LIKE many other European botanic gardens, the Royal Botanic Garden, Edinburgh, can trace its origin to a physic garden founded for the service of medicine. The original garden consisted of an unpretentious plot at Holyrood Abbey, measuring only 40 foot square, which was rented for growing medicinal plants by two friends, Dr Robert Sibbald (Fig. 1), the first Professor of Medicine in the University of Edinburgh, and Dr Andrew Balfour. Continuous development of this garden, involving several changes of site and status, has resulted in the Royal Botanic Garden of today.

Maintenance of the original garden was entrusted to a youth called James Sutherland who was to have a vital influence on its development and future history; by his industry the garden developed and soon required the addition of more land which was obtained at separate sites in 1675 and 1695. Sutherland became one of the great botanists of his day and was appointed Professor of Botany in the University of Edinburgh in 1695; thus began the union in one man of the duties of Keeper of the Botanic Garden and Professor of Botany which, apart from the years 1706–1739, was maintained until 1956. In 1699 Sutherland was further honoured by becoming King's Botanist under a warrant of King William III, and in 1710 Queen Anne created for him the post of Regius Professor of Botany.

SIR ROBERT SIBBALD BART M.D.

Fig. 1. Sir Robert Sibbald, first Professor of Medicine in the University of Edinburgh, one of the two co-founders of the Royal Botanic Garden, Edinburgh.

Following Sutherland, the Garden had two outstanding Regius Keepers during the eighteenth century: Professors Charles Alston (1716–1760) and John Hope (1761–1786). A manuscript copy of Hope's student lectures, in the library of the Garden, reveals that he was an experimental plant physiologist of great ingenuity and well informed on the research of botanists throughout Europe. Apart from plant physiology his other great interest was systematic botany, and unlike some of his contemporaries he was a strong advocate of the system of Linnaeus. He encouraged his students to explore and investigate the flora of Scotland and annually gave a gold medal for the best student's herbarium. Undoubtedly Hope and his students were the pioneer investigators of the Scottish flora, and he himself greatly influenced the work of Lightfoot who published his *Flora Scotica* in 1778. From the point of view of the future history of the Botanic Garden, Hope's greatest achievements lay in securing a permanent endowment for its maintenance from the Crown and in obtaining a new site in Leith Walk to which the plant collections were transferred in 1763.

The years from 1786 to 1820 were rather unpropitious for the history of the Botanic Garden, although some members of the staff were active in the study of the Scottish flora, most notably the great Scottish taxonomist, horticulturist and plant explorer George Don who was Principal Gardener from 1802–1806. By 1820 the Botanic Garden at Leith Walk was in a parlous state: its five acres were too small to accommodate the collections accumulated by the enthusiastic and able Principal Gardener, William McNab, the glasshouses were in dilapidated condition and the expansion of the city had encroached closely around it. Because of this a fourteen and a half acre site at Inverleith was purchased. This site formed the nucleus of the Botanic Garden of today, and adjacent properties were later acquired and added to it so that a garden of 68 acres was eventually produced. Two years were taken to complete the transfer of the plant collections from the Leith Walk Garden to Inverleith. Well established trees, some more than forty feet tall, were moved by means of a transplanting machine (Fig. 2), akin to those of today, which was designed by the resourceful McNab. He published an account of the successful tree transplanting operations in 1830 in an important paper, "Hints on the Planting and General Treatment of Hardy Evergreens in the Climate of Scotland".

Botanical Society of Edinburgh

The Regius Keeper from 1820 to 1844 was Professor Robert Graham who was forced to devote much of his efforts to making representations to improve the totally inadequate Government grants made to the Garden. These representations bore fruit, and in 1834 he was able to

This month we are publishing 4 new science books; that makes some 950 titles now in print. We also publish 35 learned scientific journals. Write now for a Cambridge subject list.*

Per-unit Systems

M. R. HARRIS,
P. J. LAWRENSON and
J. M. STEPHENSON

The fourth title in the IEE monograph series, dealing with per-unit systems in the mathematical study of electrical machines. This will be a useful book for all power engineers. £2 5s. net

The Engineering Uses of Holography

Edited by J. M. HARVEY and
ELIOTT R. ROBERTSON

This book looks at many applications of this challenging new laboratory technique, especially methods of stress and vibration analysis and measurement of transient disturbances. It contains 36 papers and is illustrated with over 130 plates. £15 net

The Biochemistry of Inorganic Compounds of Sulphur

A. B. ROY and P. TRUDINGER

A survey of the role of sulphur in biological systems, covering preparation and analysis of important compounds, sulphur enzymology and the metabolism of sulphur compounds. £6 net

Machine Tool Dynamics–an Introduction

D. B. WELBOURN and J. D. SMITH

Too much machine tool design is still based on inspired guesswork, with little understanding of the fundamental scientific principles of design. This book describes clearly and simply many modern methods of analysis, modelling and measurement, which can give a real insight into the problems facing designers. £2 net

London N.W.1

Our Breed-in.

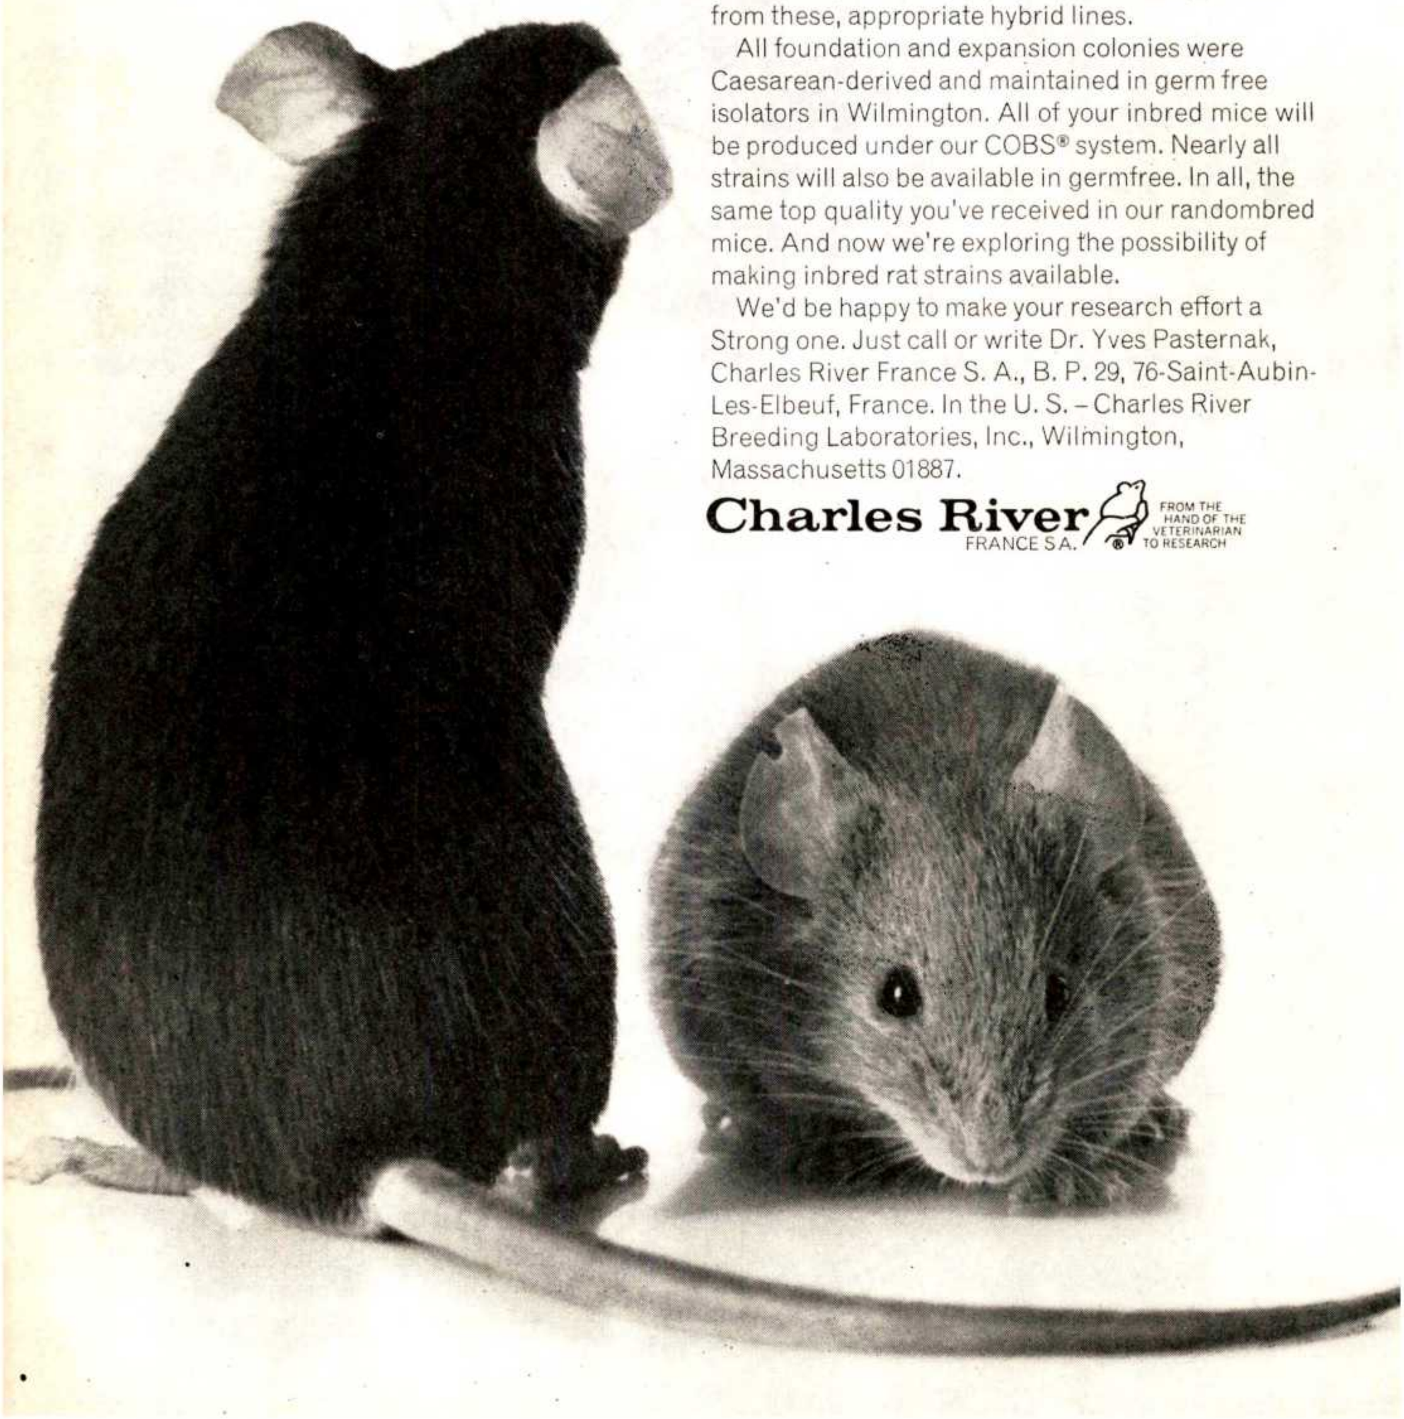
They're the class of '70. Inbred mouse strains developed and maintained by Dr. Leonell C. Strong.

These strains of mice have been the most generally accepted in cancer research. We pioneered commercial production of Charles River COBS® mice right here in Elbeuf. This Spring our Wilmington, Massachusetts "home office" will produce them commercially for the first time in the U. S. DBA/2, C57BL/6, C3H, A and BALB/c. And from these, appropriate hybrid lines.

All foundation and expansion colonies were Caesarean-derived and maintained in germ free isolators in Wilmington. All of your inbred mice will be produced under our COBS® system. Nearly all strains will also be available in germfree. In all, the same top quality you've received in our randombred mice. And now we're exploring the possibility of making inbred rat strains available.

We'd be happy to make your research effort a Strong one. Just call or write Dr. Yves Pasternak, Charles River France S. A., B. P. 29, 76-Saint-Aubin-Les-Elbeuf, France. In the U. S. – Charles River Breeding Laboratories, Inc., Wilmington, Massachusetts 01887.

Charles River
FRANCE S.A.
FROM THE HAND OF THE VETERINARIAN TO RESEARCH



open a new tropical palm house, the largest of its type in Britain, the construction of which had been financed from Government funds. Perhaps Graham's greatest achievement was the part he played in the founding and early development of the Botanical Society of Edinburgh. The Society was founded in 1836 and Graham was its first President, and strove for its success to the end of his life. Throughout its auspicious history the Botanical Society of Edinburgh has had a symbiotic relationship with the Royal Botanic Garden: the donation in 1863 of its herbarium of many thousands of specimens and in 1872 of its valuable library formed the nucleus around which the extensive herbarium and library of the Royal Botanic Garden have been built. Robert Graham would surely be happy if he could see the embryonic society which he nurtured as it is today—a body with a large, active, international membership sponsoring an important part of the tercentenary celebrations of his Botanic Garden.

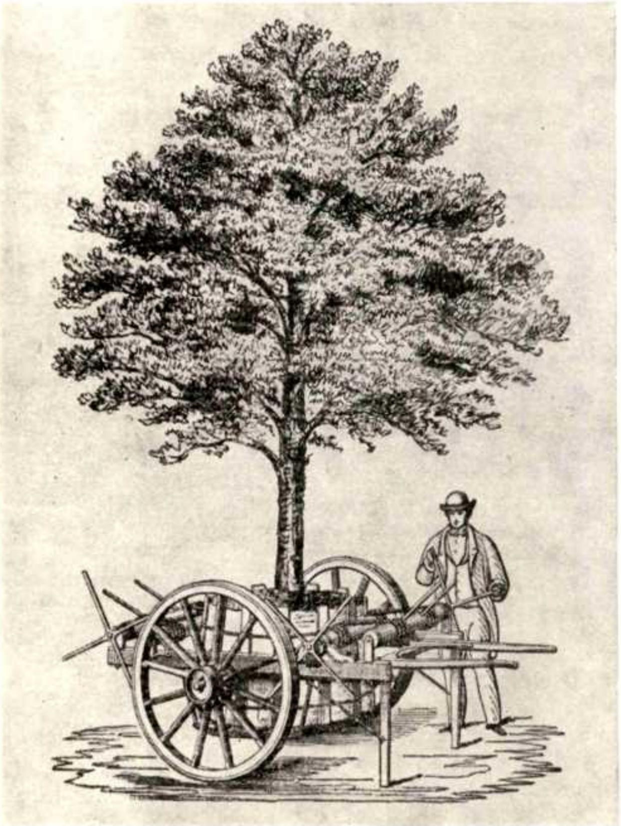


Fig. 2. Tree transplanting machine designed by William McNab and used for transplanting trees from Leith Walk to the present site of the Royal Botanic Garden in the early 1820s.

Graham died in 1845 and was succeeded by John Hutton Balfour who was appointed to the Professorship of Medicine and Botany by Edinburgh Town Council and to the posts of Regius Professor of Botany, Keeper of the Garden and Queen's Botanist by the Crown. Hutton Balfour was a notable teacher whose classes were frequently attended by between 300 and 400 students; provision of practical material for classes of this size must have been a task of considerable proportions—one day in 1873 the number of plant specimens taken from the Botanic Garden to illustrate his lectures and demonstrations was 7,000. For his students Hutton Balfour wrote textbooks almost encyclopaedic in their coverage; one of them was the first British textbook of palaeobotany—his *Introduction to Palaeontological Botany* of 1872. He also continued the emphasis on field work for which the Edinburgh Botany School had been noted for several decades, elaborating the field courses and practising what, at that time, undoubtedly was a fairly advanced ecological botany.

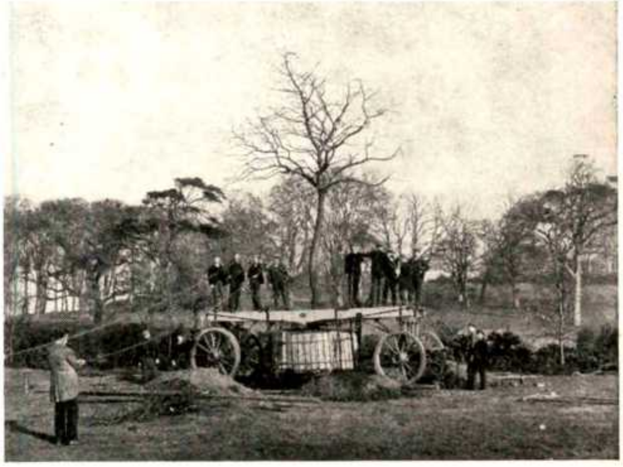

Fig. 3. Tree transplanting machine in operation during the reconstruction which took place at the end of the nineteenth century.

During Hutton Balfour's time as Keeper the fortunes of the Botanic Garden prospered. The acreage was more than trebled, largely due to the incorporation of two adjacent properties. Some of the palms in the tropical palm house, built in Graham's time, had thrived to such an extent that by the early 1850s they were sticking through the roof: their exuberance enabled Balfour to persuade the authorities that a larger palm house must be erected. Parliament voted £6,000 for the project and the new house was completed in 1858. Both palm houses are still in service, although one is 136 and the other 112 years old.

Under Hutton Balfour the Royal Botanic Garden began to assume a form which is recognizable today. He retired in 1880 and was succeeded by one of his students, Alexander Dickson, an able research worker who died after only seven years in office. The next Regius Keeper and Regius Professor of Botany was Hutton Balfour's son, Isaac Bayley Balfour, who held the posts for thirty-four years. With the appointment of Bayley Balfour the modern phase in the history of the Botanic Garden can be said to have begun. He strove tirelessly towards the reconstruction and development of the Botanic Garden and the University Department of Botany in the Garden. The year after his appointment (1889) the entire Garden came wholly under the Crown to be administered by Her Majesty's Office of Works; previously only part of the Garden had been the responsibility of the Crown. The association with the Office of Works, which later became the Ministry of Works and then the Ministry of Public Building and Works, persisted for eighty fruitful years and only came to an end last year.

Aided by a series of brilliant curators (principal gardeners), Bayley Balfour brought about enormous changes: a new range of glasshouses with a frontage of 380 feet was erected, a vast new rock garden was laid out, and extensive rearrangements involving the movement of 40-foot trees were accomplished (Fig. 3). Equally as important, Balfour reorganized the laboratories, provided new accommodation and equipment for botanical research and teaching, and created in Edinburgh a major centre of taxonomic research.

Expeditions and Expansion

The orientation of Bayley Balfour's research and that of most other botanists on the staff of the Botanic Garden during the first half of the twentieth century was brought about by the botanical explorations of George Forrest in Western China. Forrest had held a minor post in the herbarium of the Garden until in 1904 he was induced by Bayley Balfour to undertake the first of his expeditions. As a result of Forrest's introductions the staff of the Garden became particularly interested in Himalayan and West Chinese plants and specialized in such genera as *Rhododendron*, *Magnolia*, *Primula*, *Gentiana* and *Meconopsis*: specializations which are retained today and still strongly influence the work of the scientific staff. The *Notes from the Royal Botanic Garden, Edinburgh*, founded by Bayley Balfour in 1900 as the official scientific publication of the Garden, provided the medium for the communication of the increasing volume of scientific information being produced.

Bayley Balfour was succeeded in 1922 by William Wright Smith who, like both of the Balfours, was Regius Keeper for thirty-four years. During his period of office the Botanic Garden flourished, and the series of developments which have brought it to its present form continued. In 1928 a West Coast Garden of 90 acres came under the control of the Royal Botanic Garden, Edinburgh; it was part of the 10,200 acre estate of Benmore which was gifted to the nation by Harry George Younger of Benmore and Kilmun. This garden, known as the Younger Botanic Garden, was developed as a woodland garden and arboretum on a grand scale, and its provision allowed the successful growing of conifers and other species which had never thrived in Edinburgh. Wright Smith is best remembered scientifically for the description of more than 550 plant species new to science, and the monographic treatment of the genus *Primula* which he carried out in conjunction with Harold Fletcher, the present Regius Keeper. From 1930 to 1954 Wright Smith was supported by John Macqueen Cowan as Deputy Keeper; in Edinburgh, Cowan began an intensive study of the genus *Rhododendron* on which he became the recognized authority.

The years after the Second World War have seen plenty of activity regarding developments in both buildings and staffing. In the late 1940s the civil servants employed in the herbarium and laboratory were incorporated into the new Scientific Civil Service grades recommended by the Barlow Report. The size of the scientific staff was also increased so that the establishment could extend its research output, to bring it more into line with the facilities for investigation offered by the enormous collections of both living and herbarium specimens. In this respect 1951 was an *annus mirabilis* in the history of the Botanic Garden, with five members of the scientific officer grades added to the staff. University staff were also increased so that the department could participate in the explosion of botanical research in the new disciplines.

When Wright Smith died in 1956, the posts of Regius Keeper of the Garden and Professor of Botany in the University had been vested in one person for almost 220 years. Such a system carried with it an inevitable corollary: the Regius Keeper had to be a systematist to carry out the duties involved in directing the Garden, and therefore the Head of the University Botany Department was also a systematist. The arrangement had worked well in earlier times when botany was virtually synonymous with systematic botany, but with the growth of other branches of the science the University felt that it should no longer be restricted to choosing its professor from a single discipline. Accordingly the dual post was split: Harold Fletcher, who had been Deputy Keeper since 1954 when Cowan had retired, was appointed in 1956 Regius Keeper of the Garden, while Robert Brown, well known for his research in cell biology, became Regius Professor of Botany in 1958. Despite this division a close relationship has been maintained between the Royal Botanic Garden and the University Botany Department, and Fletcher was appointed an Honorary Professor of Botany in 1968. He was appointed Queen's Botanist in 1967.

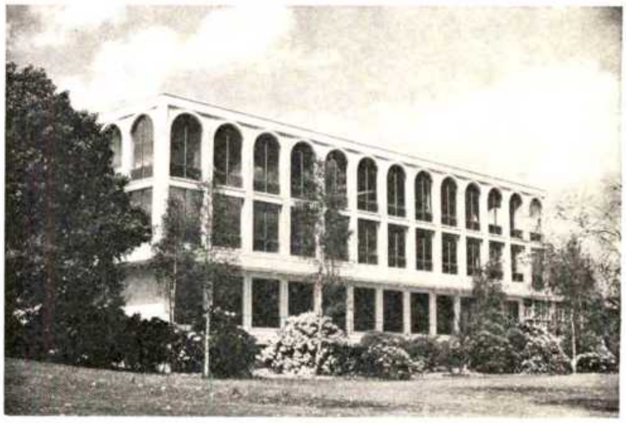

Fig. 4. The Royal Botanic Garden Herbarium, Laboratory and Library building which was completed in 1964.

Too Many Specimens

At the end of the 1950s the accommodation at the Royal Botanic Garden was grossly inadequate. Garden laboratory and administrative staff together with University staff and research students were crowded into a building which had met the spatial requirements of fifty years previously. Conditions in the herbarium were even worse: the collections were housed in an antiquated building, originally built in the early nineteenth century as an exhibition hall, and in two huts which had been erected beside it to take the overspill of specimens. It was obvious that new buildings had to be provided, and the first of these was the new Royal Botanic Garden Herbarium, Library and Laboratory building (Fig. 4), officially opened by Her Majesty the Queen in June 1964. This spacious building, which provides excellent accommodation for the herbarium, library and laboratory of the Garden, was completed just before the Tenth International Botanical Congress was held in Edinburgh in 1964 and its facilities were much admired by the visiting botanists.

The University Botany Department also required new premises and, furthermore, faced problems concerning their correct siting. The Botanic Garden was five miles from the King's Buildings complex in South Edinburgh where the rest of the university science buildings were situated, and its isolation posed considerable problems in the planning of timetables allowing students the necessary travelling time between classes, in intercommunication with other university departments, in access to their libraries, and so on. It was decided, therefore, to break the long tradition whereby university botany teaching had been carried out at the Botanic Garden and to site the new building in the science complex at King's Buildings; in 1965 it was completed. The herbarium collections and library at the Botanic Garden were, however, of vital importance to the university taxonomists, and accordingly their section of the department has remained in a refurbished part of the old building.

An inspired programme of development has also been carried out in the Botanic Garden, directed by the present Curator, Edward Kemp, whose extensive knowledge of landscaping has enabled him to make major improvements in many areas (Fig. 5). A fine new glasshouse of unique design, 420 feet long with a span of 60 feet and a height of 36 feet in its central section, was opened in October 1967 to replace the sixty year old main range which had become dilapidated. This glasshouse is divided into six large compartments, each with a different environment, and its planting has been landscaped to give as natural an effect as possible (Fig. 6).

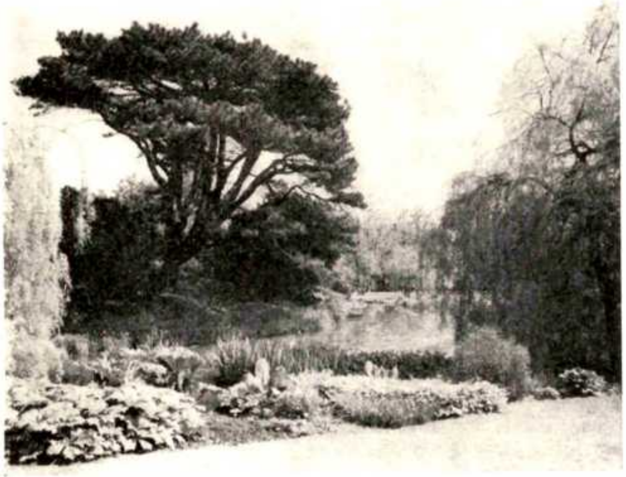

Fig. 5. A view in the present day Botanic Garden showing the pond.

Two other events in the recent history of the Garden should be mentioned here. The first was the transfer of responsibility from the Ministry of Public Building and Works to the Department of Agriculture and Fisheries for Scotland which occurred on April 1, 1969. The second was the acquisition in 1969 of part of the famous Garden of Logan in Wigtownshire, originally created by the brothers McDouall. Thus the Royal Botanic Garden, Edinburgh, now has two important annexes—the Younger Botanic Garden at Benmore and the Logan Botanic Garden.

Research Today

It seems appropriate to conclude this short history with a brief survey of the status at the present day of two of the most important functions of the Royal Botanic Garden: research and education.

The permanent research staff of the institute is relatively small, consisting of fourteen members of the scientific and experimental officer classes, supported by scientific assistants and ancillary grades. A surprisingly high research output is maintained, however, and research projects range from studies of New Guinea Orchids to the preparation of an Agaric flora of the British Isles. University taxonomic staff and research students also play a vital part in the research of the establishment; their leader, Peter Davis, Reader in the Department of Botany, has made numerous expeditions to South-West Asia, particularly Turkey, and his work, like that of Forrest in the days of Bayley Balfour, has greatly influenced the orientation of research in the Royal Botanic Garden. At present Davis's team is engaged in writing the fourth volume of a definitive *Flora of Turkey* which will comprise eight volumes in all.

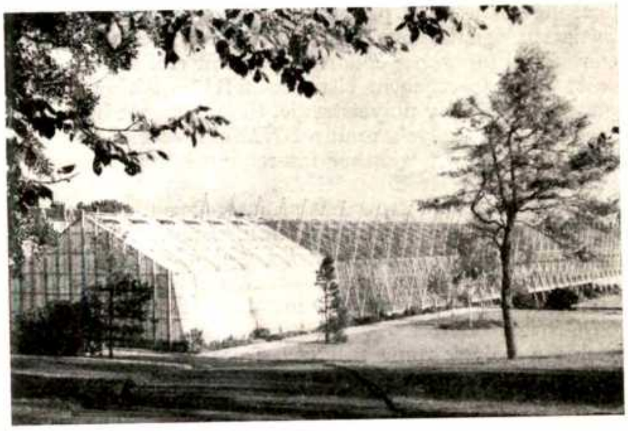

Fig. 6. The principal glasshouse range, 420 feet long, which was completed in 1967. Note the use of external supporting timbers.

Education at various levels is playing an increasingly important part in the work of the Royal Botanic Garden. The three year Horticultural Instruction Course leading to the award of the Diploma in Horticulture (Edinburgh), which has been established for nearly eighty years, continues to flourish and has an annual intake of fifteen students. The instruction in this course is carried out by staff members and also by specialists from other institutes. University and Botanic Garden staff share the teaching of the one-year postgraduate course for the University of Edinburgh Diploma in Plant Taxonomy, while members of the Garden staff who hold honorary lectureships in the University also supervise PhD students. Education of the general public is also acknowledged to be an important function of the Garden, and to further this end a large new demonstration garden which concentrates on the biology of plants was laid out in 1961, and educational sound guides of the new glasshouse range have recently been provided. An anonymous donor was so impressed with the educational potentialities of the Garden that he gave £50,000 for the construction of an Exhibition Hall. This hall, equipped with a series of imaginative exhibits in which the use of audio-vision units plays an integral part, will be officially opened during the tercentenary celebrations.

The Intercistronic Divide: Translation of an Intercistronic Region in the Histidine Operon of *Salmonella typhimurium*

by
MATTHEW M. RECHLER
ROBERT G. MARTIN

National Institutes of Health,
Bethesda, Maryland 20014

A frameshift mutation near the end of the *hisD* gene of the histidine operon results in the production of an active *hisD* gene product. Analysis of the C-terminal sequence of the mutant protein establishes that the normal *in vivo hisD* chain termination codon can be UAA or UGA but not UAG, and demonstrates the existence of an intercistronic region between two genes of the operon.

STEITZ has recently demonstrated that the codon AUG is the polypeptide chain initiation signal for each of the three cistrons of the RNA phage R17 (ref. 1). In no case is the initiation signal immediately preceded by a chain termination signal (nonsense codon), so that intercistronic regions exist between adjacent cistrons of R17. Although RNA phages are clearly polycistronic, they may not be suitable models for the polycistronic mRNAs of bacterial operons[1,2]. It is not known whether intercistronic regions exist in bacterial polycistronic mRNAs.

We demonstrate here that an intercistronic region does exist between the second and third structural genes of the histidine operon of *Salmonella typhimurium*. The *his* operon consists of an operator region and nine contiguous structural genes arranged in the order: *operator-hisGDCBHAFIE* (ref. 3). Transcription of the *his* operon yields a polycistronic mRNA[4], from which the second, third and sixth genes (*hisD*, *hisC* and *hisA*) are translated at the same frequency[5]. We describe a frameshift mutation* near the end of *hisD*, *his-2352*, which results in an altered reading frame that allows polypeptide elongation beyond the normal *hisD* termination codon. From the altered *C*-terminal amino-acid sequence of the *hisD* product (histidinol dehydrogenase) in the mutant strain, we deduce that the normal chain termination codon at the end of *hisD* can be UAA or UGA but not UAG; and that an intercistronic region does exist beyond the normal peptide termination signal of *hisD* and contains at least one nucleotide, C, before the next initiation signal. It seems, moreover, that translation of the intercistronic region severely reduces the frequency of translation of the immediately distal cistron.

The *his-2352* mutation was originally selected by Voll[7] in a strain of *S. typhimurium* which contained a histidine operator constitutive mutation, *hisO1242*, and wild type histidine structural genes. Constitutive strains such as *hisO1242* make about ten times as much of the histidine biosynthetic enzymes as does wild type (*S. typhimurium* LT2) (ref. 3) and exhibit the following phenotype: they form wrinkled colonies at 37° C on agar containing 2 per cent glucose, and do not grow at 43° C (ref. 8). By contrast, strains making approximately wild type levels of the distal histidine enzymes (for example, wild type itself, or constitutive strains with a secondary strongly polar mutation) form smooth colonies at either 37° C or 43° C (ref. 8). Voll[7] examined spontaneous revertants of *hisO1242*, selected as smooth colonies growing at 43° C on minimal medium with 2 per cent glucose. Each revertant contained a second mutation in addition to *hisO1242*. One of these, *his-2352*, was mapped (by transduction into a series of overlapping deletions) in the operator-distal part of *hisD* (region VIII), or the proximal part of *hisC* (region I). Enzyme specific activities in *hisO1242 his-2352* relative to *hisO1242* were: *G-enzyme*, 100 per cent; *D-enzyme*, 37–72 per cent; *C-enzyme*, 2 per cent; *B* and *A-enzymes*, 10 per cent. The marked polar reduction of operator-distal gene products could account for smoothness and growth at 43° C. The 2 per cent *C-enzyme* (aminotransferase) activity (corresponding to 20 per cent of the level in wild type cells grown either in minimal media or with excess histidine) allowed growth in minimal media at a nearly normal rate.

It was not known whether the *his-2352* mutation was in *hisD* or *hisC*. On repeated examination, *D-enzyme* (histidinol dehydrogenase) activity in *hisO1242 his-2352* was 65 per cent (± 10 per cent) of that in *hisO1242*. Cell-free extracts of the two strains were examined by acrylamide gel electrophoresis (Fig. 1). The electrophoretic mobilities of wild type histidinol dehydrogenase (from *hisO1242*) and the enzyme from *hisO1242 his-2352* are clearly different. The simplest interpretation is that the primary structure of the histidinol dehydrogenase is altered in *hisO1242 his-2352*. The mutation has therefore been designated *hisD2352*.

Unusual Properties of *hisD2352*

Merely placing the mutated site in *hisD2352* in *hisD*-region VIII, however, does not explain its special properties. First, *hisO1242 hisD2352* is unusually polar, making no more than 10 per cent of the distal enzymes (relative to *hisO1242*). By contrast, five other polar mutations in *hisD*-region VIII are only weakly polar, making ~50 per cent of the distal enzymes (unpublished results of C. B. Bruni and M. M. R.). The strong polarity of *hisD2352* resembles more closely that of mutations at the beginning of *hisC*, which make approximately 10 per cent of the later gene products[13,14]. Second, *hisD2352* is unusual in that it affects more profoundly the expression of the immediately succeeding gene, *hisC* (2 per cent of the constitutive level), than of the later cistrons, *hisB*, *hisH*, and so on (10 per cent of the constitutive level). Instances of non-coordinate polarity in other bacterial operons have been explained by the existence of internal promoters[2], but the extremely weak promoter at *hisB* cannot account for this difference[15]. Because the wild type aminotransferase is fully active in mixed extracts with the aminotransferase from *hisO1242 hisD2352*, the low activity cannot be attributed to an enzyme inhibitor. The specific reduction of aminotransferase activity in *hisO1242 hisD2352* thus seems to be a direct consequence of the *hisD* mutation.

We have considered several mechanisms by which *hisD2352* could produce a structurally altered histidinol dehydrogenase, a coordinate 10 per cent polarity for *hisB*, *hisH* and so on, and a special decrease in aminotransferase activity. (1) A frameshift mutation in *hisD* might allow translation of the dehydrogenase protein beyond the normal termination signal, until a new chain termination codon is reached in the intercistronic region or in *hisC*. Reinitiation of protein synthesis might occur either at 10 per cent of the normal frequency within *hisC* (the aminotransferase would have a reduced molecular activity—specific activity of the pure enzyme[16]—because it lacked part of its normal N-terminal end), or at 2 per cent of normal frequency at the normal *hisC* initiation triplet or within *hisC* (without reduction in the aminotransferase molecular activity) and an additional 8 per cent of normal frequency at the beginning of *hisB*. Alternatively, (2) *hisD2352* might contain an out-of-phase deletion of part of the *hisD–hisC* intercistronic divide, including all or part of the normal termination codon at the end of *hisD*. Reinitiation of protein synthesis would occur as in (1). Or (3) separate point mutations in *hisD* and *hisC* might be present. To distinguish these possibilities, we attempted to relieve the polarity of *hisO1242 hisD2352* by further mutation.

---

* A frameshift mutation is one which results from the addition or deletion of one or a limited number (but not three or a multiple of three) of bases from the DNA[6].

HisD2352 is a Frameshift Mutation

Analysis of non-polar constitutive revertants of *hisO1242 his D2352* indicates that *hisD2352* is a frameshift mutation. These mutants were selected as aminotriazole-resistant wrinkled colonies on minimal agar containing 2 per cent glucose. Aminotriazole is an inhibitor of the *B-enzyme*[17]. At appropriate concentrations it inhibits the growth of the prototrophic polar *hisO1242 hisD2352* but not *hisO1242* (which lacks the polar secondary mutation and has tenfold higher levels of the *B-enzyme*). Wrinkled aminotriazole-resistant non-polar revertants were induced by ICR-191, an acridine half-mustard highly specific for inducing frameshift mutations[18], but not by N-methyl-N′-nitro-N-nitrosoguanidine, primarily a base-substituting agent. The enzyme profiles of the revertant strains are shown in Table 1. The *G*, *C* and *B-enzyme* activities were equal to those of *hisO1242* (± 1 standard deviation); that is, polarity was completely relieved as expected. Histidinol dehydrogenase (*D-enzyme*) activity, by contrast, was further reduced below *hisO1242 his D2352* levels, to 10–25 per cent of the *hisO1242* value. The complete restoration of aminotransferase activity with additional loss of histidinol dehydrogenase activity makes it extremely unlikely that *hisD2352* contains separate point mutations in *hisD* and *hisC* (for two corrective mutations would be required) or a deletion of the intercistronic region and part of *hisC*. We conclude that *hisD2352* is a frameshift mutation near the end of *hisD* and propose that the wrinkled revertants contain a second frameshift mutation which corrects the reading frame error of *hisD2352* before the normal *hisD* termination signal. The presence of both frameshift mutations in the revertants further reduces the specific activity of the histidinol dehydrogenase below that of *hisD2352*.

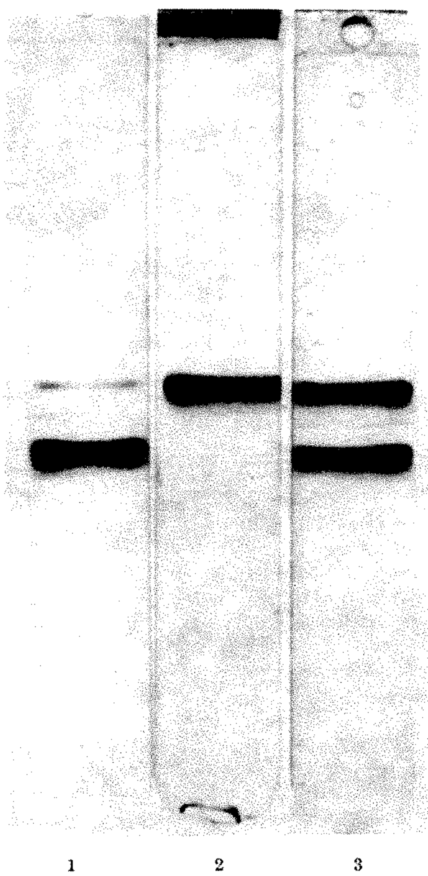

Fig. 1. Acrylamide gel electrophoresis of extracts of *hisO1242* and *hisO1242 his-2352*. Bacterial strains were grown to late logarithmic phase at 37° C with aeration in 200 ml. of minimal medium E[9] supplemented with 0·5 per cent glucose. Cells were harvested by centrifugation, resuspended in 2·5 ml. of 0·05 M Tris-HCl (*p*H 7·5), and disrupted in a French pressure cell at 10,000 lb inch^{-2}. The extracts were clarified by centrifugation at 27,000*g* for 25 min. The supernatant fractions were passed through a 9 × 1 cm column of 'Sephadex G-50', equilibrated with the same Tris-HCl buffer, and the excluded fractions which contained the protein were collected. Extracts were assayed for histidinol dehydrogenase[10]. Disc gel electrophoresis was performed at *p*H 9·5 according to Davis[11]. (1) *hisO1242*, (2) *hisO1242 his-2352*, (3) both. Samples (250 ul.) with 0·05 units of dehydrogenase in Tris-HCl containing 10 per cent sucrose were layered above the spacer gel. The dehydrogenase migrated downward toward the anode. The lower gel margin corresponds to the bromphenol blue front. Gels were stained directly for histidinol-specific dehydrogenase by reduction of a tetrazolium dye (ref. 12, omitting gelatine). The faint upper band in sample (1), also present in (2) and (3), is observed even without adding histidinol, and probably represents a dehydrogenase with different substrate specificity. The distinct electrophoretic mobilities of the wild type and *his-2352* histidinol dehydrogenases are also observed when these strains are grown in the presence of excess histidine, in a non-constitutive genetic background, and when both fully purified enzymes are compared.

Table 1. ENZYME LEVELS IN REVERTANTS OF *hisO1242 hisD2352*

Strains	Enzyme specific activity Synthetase *G*	Dehydrogenase *D*	Aminotransferase *C*	Phosphatase *B*
hisO1242	1·00	1·00	1·00	1·00
hisO1242 hisD2352	0·90	0·73	0·02	0·08
TM217	0·93	0·14	0·81	0·87
TM218	0·98	0·22	0·97	1·00
TM219	1·14	0·19	1·02	1·03
TM220	0·95	0·11	0·86	0·94

The lower four strains (TM217–220) are independently isolated wrinkled revertants obtained from *hisO1242 hisD2352*. They were isolated from minimal plates containing 2 per cent glucose, 5–15 mM 3-amino-1,2,4-triazole, a competitive inhibitor of imidazole glycerol phosphate dehydrase (*B-enzyme*) to suppress background growth[17], and 0·4 mM adenine (to overcome an aminotriazole-induced defect in purine biosynthesis). Approximately 2 × 10^{6} bacteria were spread on each of sixty plates. One-half of the plates received crystals of NG, the other half crystals of 'ICR–191' (a gift of Dr Hugh J. Creech). TM218–220 were induced by 'ICR–191', no wrinkled revertants with non-polar phosphatase levels were induced by N-methyl-N′-nitro-N-nitrosoguanidine. TM217 probably arose spontaneously, for it was located in the periphery of the plate, well outside the ring of mutants induced by 'ICR–191'. Cell-free extracts were prepared as described in the legend to Fig. 1, except that media were supplemented with 0·1 mM L-histidine. Phosphoribosyl-ATP synthetase (*G-enzyme*) (ref. 19 as modified by H. J. Whitfield, jun., manuscript in preparation), histidinol dehydrogenase (*D-enzyme*)[12], histidinol phosphate aminotransferase (*C-enzyme*)[20], and histidinol phosphate phosphatase (*B-enzyme*)[21], were assayed as described previously. Protein was estimated by the method of Lowry *et al.*[22] Enzyme specific activities are given relative to *hisO1242*. All assays were performed at least in duplicate. The average phosphatase level for *hisO1242 hisD2352* in many different experiments was 0·10 rather than 0·08 as observed in this experiment. Aminotransferase values never exceeded 0·02.

HisD2352 differs from other frameshift mutations in *hisD*-region VIII in that it is strongly polar and preferentially affects aminotransferase activity. Both effects may be explained by the translation of *hisD* beyond its normal termination signal. The frameshift resulting from the addition or deletion of bases in *hisD2352* leads to new codon groupings specifying the addition of different amino-acids to the carboxy end of histidinol dehydrogenase, until a chain termination signal in the new reading frame is reached. We have found that the first new nonsense triplet arises beyond the normal *hisD* termination codon.

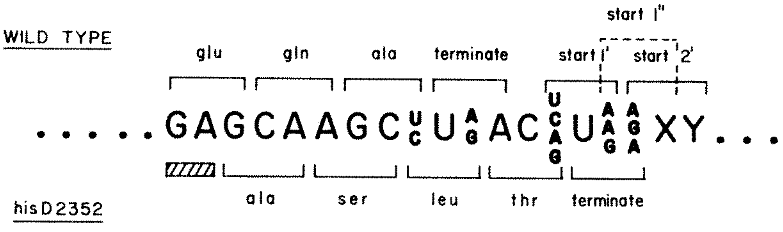

Fig. 2. Sequence of the mRNA corresponding to the end of *hisD* and the start of the intercistronic region. The deletion of two bases (GA) indicated by the hatched area most simply generates the sequence of the four C-terminal amino-acids in the mutant dehydrogenase. The same reading-frame and amino-acid sequence could, however, arise by adding one base to the first GA shown to generate an additional arginine (AGA, CGA) or glycine (CGA) codon. Glycine has been recovered in varying amounts after acid hydrolysis of peptide R eluted from paper; it is not clear if this comes entirely from the paper blank. Arginine, if present, would be released as the free amino-acid on tryptic digestion, but would not be detected on peptide mapping because the wild type dehydrogenase already has a free arginine spot. Whether the mutational event in *hisD2352* is a +1 addition or −2 deletion does not affect the sequence analysis of the C-terminal region of the enzyme or of the intercistronic space. The overlapping sequences uniquely define all amino-acid codons as shown and the normal termination signal as UNA, but do not eliminate the possibility that the termination codon is either UUA or UCA.

This implies that the nucleotides specifying the normal C-terminal amino-acid(s) of histidinol dehydrogenase, as well as the *hisD* termination codon itself, and at least part of the intercistronic space are translated out-of-phase in *hisD2352* as the C-terminal portion of its histidinol dehydrogenase.

The Intercistronic Region

To delineate the normal intercistronic region, we analysed the C-terminal sequence of histidinol dehydrogenase from *hisO1242 hisD2352*. Yourno previously reported the purification[23] and tryptic peptide map[24] of the wild type enzyme from *hisO1242*. He identified the C-terminal tripeptide, T18, and established its sequence as Glu-Gln-Ala[24] (J. Yourno, personal communication). We have purified the dehydrogenase from *hisO1242* and *hisO1242 hisD2352* by analogous procedures. Tryptic peptide maps[25] of the mutant dehydrogenase show the unique disappearance of the wild type peptide, T18, and the appearance of a single new peptide, R. On acid hydrolysis, peptide R yields equimolar amounts of alanine, threonine, leucine and serine. Carboxypeptidase A digestion[26] of histidinol dehydrogenase from *hisD2352* leads to the rapid release of threonine and leucine, and the slower release of serine and alanine with a strong suggestion that the order is Ala-Ser-(Leu,Thr). By hydrazinolysis[27] threonine was identified as the C-terminal amino-acid. Thus, the C-terminal sequence of wild type histidinol dehydrogenase, Glu-Gln-Ala, has been changed in *hisD2352* to Ala-Ser-Leu-Thr. The reduction of overall negative charge that results from the loss of a glutamic acid residue is consistent with the slower electrophoretic mobility toward the anode of the mutant enzyme (Fig. 1).

Using the amino-acid sequences of the C-terminal ends of wild type and mutant dehydrogenases, and the known codon assignments, the nucleotide sequence of the mRNA of this region can be deduced. The C-terminal sequence of the enzyme synthesized in *hisO1242 hisD2352* can be generated from the wild type sequence by a + reading-frame shift[6], that is, from a two-base deletion or a one-base addition (Fig. 2). The finding that -Leu-Thr is the C-terminal sequence in the mutant dehydrogenase indicates that the normal *hisD* terminator codon must be UNA (presumably one of the nonsense codons, UAA or UGA); a third nonsense codon, UAG, is excluded. The possibility that the normal *hisD* termination signal contains two adjacent nonsense codons (as in bacteriophage R17) (ref. 28) is also eliminated.

The presence of the nucleotide C, following the *hisD* termination signal, would establish the existence of an intercistronic region before the initiation codon of *hisC*, provided that codon did not begin with the nucleotide C. Probably the aminotransferase is synthesized, as are other bacterial and bacteriophage proteins, with N-terminal N-formylmethionine (coded by AUG or GUG)[29]. Analysis of the purified aminotransferase reveals serine as the only N-terminal amino-acid. (In addition to the identification of DNP-serine by the fluorodinitrophenol method[30], we have now identified N-terminal serine both by the dansyl chloride[31] and acetic anhydride acetylation[32] reactions. Quantitation of N-terminal amino-acids by the method of Stark and Smyth[33] revealed 0·7 serine equivalents and less than 0·2 equivalents of all other amino-acids.) N-Terminal serine might arise after cleavage of formylmethionine[29] or truly be the initial amino-acid. Because no codon for formylmethionine or serine begins with C, this nucleotide must be part of the intercistronic space.

If serine were the *hisC* initiation signal, the earliest possible initiator codon would be 1″ in Fig. 2; that is, the intercistronic region would consist of three nucleotides, CNU. In the more likely event that a formylmethionine codon is the aminotransferase initiator, the earliest initiation could occur at codon 1′ (leaving the single nucleotide, C, as the intercistronic space) or at 2′ (separated by the four nucleotides, CNUPu, from the *hisD* termination signal). Alternatively, the intercistronic space might be still longer.

The sequence analysis establishes that there is normally an intercistronic space, and that at least part of it is translated as a result of the *hisD2352* mutation. It is not clear, however, how translation of five additional nucleotides (the normal *hisD* termination codon and two succeeding nucleotides) inhibits the expression of *hisC* in *hisO1242 hisD2352*. The preferential inhibition of *hisC* activity can be explained either by assuming that *hisC* is translated less frequently than *hisB*, or that it is translated at the same frequency but yields an aminotransferase with a reduced molecular activity. The following experiments argue against the latter possibility. Extracts from *hisO1242* and *hisO1242 hisD2352* give a reaction of identity in Ouchterlony double diffusion experiments with absorbed antiserum[14] against purified wild-type aminotransferase. This suggests either that the aminotransferase is identical in both strains or that the antiserum contains no major component directed against the N-terminal end of the aminotransferase. In quantitative experiments, a constant amount of antiserum neutralizes the same number of units of aminotransferase activity in extracts of *hisO1242* and *hisO1242 hisD2352*, supporting the conclusion that the aminotransferase has identical molecular activity in the two strains. Otherwise, the data require that in extracts of *hisO1242 hisD2352* both the reactivity with antiserum and the activity of the aminotransferase decrease to precisely the same extent, from 10 per cent of *hisO1242* levels (that found for *hisB*, *hisH* and so on, in *hisO1242 hisD2352*) to 2 per cent of *hisO1242* levels. Not only is this parallel loss most unlikely, but it clearly conflicts with the result of the double diffusion experiments; the aminotransferase in the mutant strain has not lost a major antigenic determinant. Thus the aminotransferase in *hisO1242 his D2352* has the same molecular activity as that found in *hisO1242*.

The reduced aminotransferase activity in *hisO1242 hisD2352* must therefore result from a low frequency of initiation at the normal *hisC* initiator or at a new internal initiation site within *hisC*. In either case, initiation at the normal *hisC* initiator must be reduced or abolished in *hisO1242 hisD2352*. If the wild type *hisC* initiation signal is either codon 1′, 1″, or 2′ (Fig. 2), then the same nucleotide(s) in *hisO1242 hisD2352* must specify both termination of *hisD* and initiation of *hisC*, and be recognized by both polypeptide termination factors and initiation factors[29]. This overlap might reduce the efficiency of initiation at *hisC* but allow synthesis of a completely normal aminotransferase. This interpretation is analogous to the proposal[34] that following premature polypeptide chain termination in certain mutants of bacteriophage T4, ribosomes may phaselessly wander back to an earlier polypeptide starter signal.

On the other hand, if none of the start signals shown in Fig. 2 is the normal *hisC* initiator, then the wild type intercistronic space must consist of more than five nucleotides. Translation of the *hisD2352* dehydrogenase would terminate entirely within the intercistronic space. Although the nucleotide signals for termination of *hisD* and initiation of *hisC* would not overlap, some steric interference of polypeptide termination factors with initiation factors or terminating ribosomes with initiating ribosomes might still occur. Alternatively, translation of the intercistronic space might disrupt local mRNA secondary structure and thereby interfere with initiation at *hisC*. Whatever the mechanism, it seems that the intercistronic divide is vital in controlling the initiation of protein synthesis in the internal cistrons of a polycistronic message.

Embryopathic Effects of 7,12-Dimethylbenz(a)anthracene and its Hydroxymethyl Derivatives in the Sprague–Dawley Rat

by

P. SIMS
Chester Beatty Research Institute,
Royal Cancer Hospital, London

7,12-Dimethylbenz(a)anthracene and one of its hydroxymethyl derivatives have been shown to cause a variety of foetal abnormalities, especially when administered on day 13 of pregnancy. It is suggested that derivatives of benz(a)anthracene must have active side chains situated at C-7 and C-12 for embryopathic activity.

THE polycyclic carcinogenic hydrocarbon, 7,12-dimethylbenz(a)anthracene (DMBA), produces selective necrosis of the adrenal cortex in the mature rat[1]. The main products of the metabolism of DMBA by rat liver homogenates are the isomeric monohydroxymethyl derivatives, 7-hydroxymethyl-12-methylbenz(a)anthracene (7-OHM-12-MBA) and 12-hydroxymethyl-7-methylbenz(a)anthracene (12-OHM-7-MBA)[2]; 7-OHM-12-MBA is a more potent adrenocorticolytic agent than DMBA[3,4], whereas 12-OHM-7-MBA has no adrenocorticolytic effect[3]. What follows is a preliminary report of investigations of the effects of DMBA and its monohydroxymethyl derivatives on the pregnant rat and rat foetus.

Female non-parous Sprague–Dawley rats, 220–300 g in weight, were caged with males, and the day on which spermatozoa were found in the vaginal smear was designated day 0 of pregnancy. When rats were treated after implantation, laparotomies were performed before treatment to confirm pregnancy and to determine the number of implantation sites. As a routine practice the rats were killed with chloroform on day 20 of pregnancy, the day before expected delivery. All foetuses were examined macroscopically, measured and weighed, and representative examples necropsied or studied by freehand razor sections. At least two foetuses from each litter were fixed in 95 per cent ethanol and the skeletal tissues stained with alizarin red. All placentae were weighed, and several from each mother were retained for histological examination. The maternal adrenals and ovaries were also studied histologically.

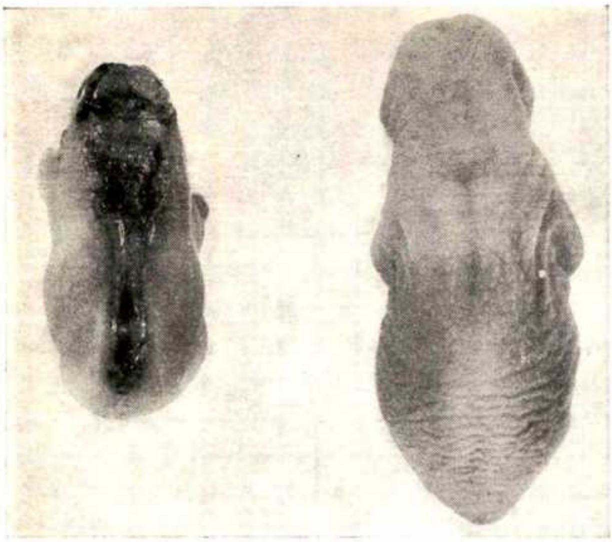

Fig. 1. Foetus from a litter of a rat treated with 7-OHM-12-MBA on day 13 of pregnancy and killed on day 20. Note the posterior encephalocele, the spina bifida extending to the lumbar region, and the marked stunting. Right, control foetus (× c. 1·5).

Effects of 7-OHM-12-MBA

7-OHM-12-MBA was dissolved in olive oil and emulsified with saline, giving a final concentration of 3 mg 7-OHM-12-MBA per ml. of 30 per cent oil emulsion. Control rats received an equivalent volume of emulsion containing no hydrocarbon.

Table 1. EMBRYOPATHIC EFFECTS OF 7-OHM-12-MBA (2·5 mg/100 g MATERNAL BODY WEIGHT) IN THE SPRAGUE–DAWLEY RAT

Days pregnant when treated with 7-OHM-12-MBA	No. rats treated	Total No. of implantations	No. resorptions* (per cent)	No. surviving foetuses with malformations

18	4	51	1 (2)	0

* Resorption rate in control groups: mean 7 per cent; range 2–29 per cent.
† Note 100 per cent of surviving foetuses have malformations.

In the first experiment rats were treated with a uniform dose of 7-OHM-12-MBA, each rat receiving one single intravenous injection at a dose of 2·5 mg/100 g body weight; this was investigated from day 2 to day 18 of pregnancy (Table 1). 7-OHM-12-MBA administered between day 3 and day 10 of pregnancy increased the resorption rate and this reached a maximum (100 per cent) on day 8; no gross skeletal or other malformations were found in any of the survivors. In the control series an average of 7 per cent of embryos resorbed between implantation and term, although in a few groups a resorption rate of up to 29 per cent was found. Treatment between day 11 and day 15 of pregnancy caused teratogenic effects, but the resportion rate was within normal limits (Table 1).

Treatment on day 12 to day 14 affected every foetus in each litter, each foetus showing almost identical pathology to its littermates: stunting, lordosis of cervical and upper thoracic parts of the vertebral column, and an encephalocele and a spina bifida (Fig. 1). They all seemed to be oedematous: this was caused by a layer of gelatinous material in the deep part of the dermis and in the underlying subcutaneous tissues.

The encephalocele, which was covered with an attenuated layer of skin, was about the same size in each foetus and involved the posterior part of the skull. The opening in the skull, through which the posterior parts of the brain protruded, was caused by partial or complete failure in the development of the interparietal and occipital bones (Fig. 2). The spina bifida and the associated meningomyelocele varied in size according to the day of treatment with 7-OHM-12-MBA. The most severe lesion followed treatment on day 13, when the defect involved almost the entire length of the vertebral column (Fig. 1); with treatment on day 12 the defect extended to the thoracic region, while the treatment on day 14 produced a lesion that involved only the cervical region. There was no obvious histological abnormality of the brain or of the spinal cord. The vertebral arches in the affected parts of the spine were severely stunted and the remnants were everted. The alizarin red preparations revealed other skeletal malformations, which were also most severe after treatment on day 13 (Fig. 2). These were partial or complete failure of development of the supraspinous portion of the scapula, complete inhibition or severe retardation of rib development, and shortening of some of the digits of the forepaws. Treatment on day 11 or day 15 of pregnancy produced similar but less severe teratogenic effects.

No malformations of the axial skeleton or other bony abnormalities, except for one foetus with a hypoplastic mandible, have been found in about 2,000 control foetuses.

A significant reduction in placental weight occurred during the 11 to 14-day treatment period and was most marked with treatment on day 12; this was associated with a proportionate reduction in foetal size.

Histologically, the placentae showed a relatively poor development of the syncytiotrophoblast; the cytotrophoblast, which contained cystic areas, showed an increase in nuclear pleomorphism and more extensive necrosis than in controls. The ovaries showed no histological abnormality.

The adrenal glands of every mother treated with 7-OHM-12-MBA were necrotic and the adrenals of their foetuses showed interesting histopathological changes: for example, in the litters treated on day 17, there was extensive necrosis of the central parts of the glands[4a].

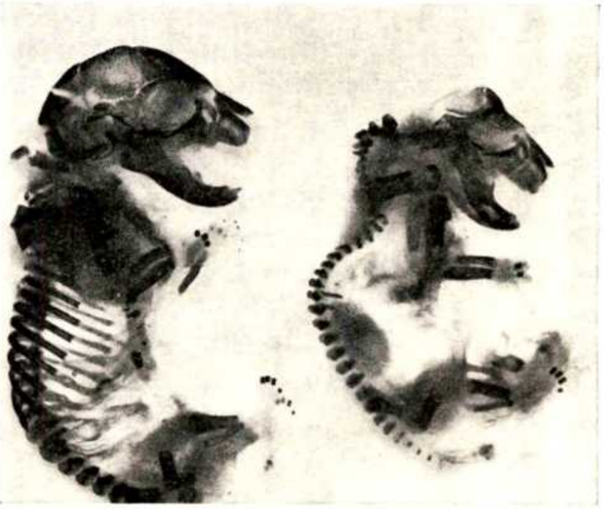

Fig. 2. Right, foetus from a litter of a rat treated with 7-OHM-12-MBA on day 13 of pregnancy. Note the absence of the interparietal and occipital skull bones, the incomplete development of the scapula, the almost complete absence of ribs and the severe cervico-thoracic lordosis. Left, control foetus (alizarin red, × c. 1·7).

Table 2. EFFECT OF VARYING THE DOSE OF 7-OHM-12-MBA ON THE EMBRYOPATHIC EFFECTS PRODUCED WITH TREATMENT AT DAY 8 OF PREGNANCY

7-OHM-12-MBA (mg/100 g maternal body weight)	No. rats treated	No. rats surviving to day 20	Total No. implantations	No. resorptions (per cent)*	No. surviving foetuses with malformations
0·1	3	3	41	1 (2)	0
0·5	3	3	46	4 (9)	0
1·0	2	2	29	5 (17)	10
1·5	3	3	42	10 (24)	14
2·0	3	3	40	22 (55)	5
2·5	3	3	30	30 (100)	—

* Resorption rate in control groups: mean 5 per cent.

The results of varying the dose of 7-OHM-12-MBA at day 8 of pregnancy are shown in Table 2. The resorption rate increased in proportion to the dose of 7-OHM-12-MBA and, as already indicated, it was 100 per cent with a dose of 2·5 mg/100 g maternal body weight. With doses of between 1·0 mg and 2·0 mg/100 g maternal body weight, teratogenic effects were produced in some of the surviving foetuses. The malformations had no special predilection for the axial skeleton, and included facial cleft, cleft lip, cleft palate, eventration of abdominal viscera, encephalocele, microphthalmia, cleft mandible, hypoplasia of mandible and maxilla, talipes, syndactyly, agenesis of kidney, cervical spina bifida, short tail, fused ribs and fused cervical vertebral arches. There was a reduction in the foetal and placental weights and this was more or less in inverse proportion to the dose of 7-OHM-12-MBA.

Varying the dose of 7-OHM-12-MBA at day 13 of pregnancy showed that a dose of 0·1 mg or 0·5 mg/100 g maternal body weight did not increase the resorption rate or produce teratogenic effects. With a dose of 1·0 mg/100 g maternal body weight or greater, however, all of the foetuses surviving to day 20 of pregnancy had axial skeleton malformations of the type described above. The encephalocele was of constant appearance, but the extent of the spina bifida varied with the dose of 7-OHM-12-MBA: 1·0 mg–2·0 mg/100 g maternal body weight produced a spina bifida involving the cervical and thoracic parts of the vertebral column whereas 2·5 mg–3·5 mg/100 g maternal body weight caused a lesion extending to the lumbar segments. The weights of foetuses and placentae were reduced and, in general, there was a direct relationship between dose and effect. The resorption rate was not significantly increased except with doses of 3 mg/100 g maternal body weight or greater; a dose of 4 mg/100 g body weight was extremely toxic for the mothers, and none survived to day 20.

There was a fairly close correlation between the dose of 7-OHM-12-MBA, the degree of damage of the maternal adrenal cortex, and the extent of the teratogenic effects.

Effects of DMBA, 12-OHM-7-MBA and 7-OHMBA

The effects of administering DMBA, 12-OHM-7-MBA, and a related benz(a)anthracene derivative, 7-hydroxymethylbenz(a)anthracene (7-OHMBA), on day 8 or day 13 of pregnancy, were studied. A single intravenous injection of an emulsion of DMBA or 12-OHM-7-MBA (2·5 mg/100 g maternal body weight), or a single intraperitoneal injection of 7-OHMBA (2·5 mg or 3·5 mg/100 g maternal body weight), dissolved in olive oil, was given. Control groups received an equivalent volume of emulsion or olive oil without the hydrocarbon.

The results are summarized in Table 3.

12-OHM-7-MBA and 7-OHMBA did not significantly increase the resorption rate or produce teratogenic effects on day 8 or day 13 of pregnancy. In contrast, treatment with DMBA, 2·5 mg/100 g maternal body weight, on day 8 of pregnancy increased the resorption rate, but not to the same extent as the equivalent dose of 7-OHM-12-MBA. A proportion of the surviving foetuses had malformations; the range and type were similar to that found with low doses of 7-OHM-12-MBA on day 8 of pregnancy.

DMBA treatment on day 13 of pregnancy did not increase the resorption rate, but teratogenic effects were produced and the malformations were similar to, but less severe than, those produced by 7-OHM-12-MBA on day 13. Over half of the surviving foetuses had a small posterior encephalocele, but there was no obvious spina bifida in any of them. Alizarin red preparations, however, revealed that whether or not there was an encephalocele, in every foetus the interparietal and occipital bones of the skull were incompletely developed and in some cases totally absent. Some foetuses showed eversion of the arches of the upper cervical vertebrae, and incomplete development of the supraspinous wing of the scapulae and the ribs. A dose of 2·5 mg/100 g of DMBA was highly toxic to the mothers (Table 3). Treatment with DMBA on day 8 or day 13 of pregnancy induced massive necrosis of the inner zones of the cortex of all the maternal adrenal glands.

Table 3. EMBRYOPATHIC EFFECTS OF THE DIMETHYL AND HYDROXYMETHYL DERIVATIVES OF BENZ(A)ANTHRACENE FOLLOWING TREATMENT AT DAY 8 OR DAY 13 OF PREGNANCY

Benz(a)anthracene derivative	No. rats treated	No. rats surviving to day 20	Total No. implantations in surviving rats	No. resorptions (per cent)*	No. surviving foetuses with malformations
Day 8 treatment					
DMBA	9	5	64	39 (61)	7
12-OHM-7-MBA	5	5	63	10 (16)	0
7-OHMBA	4	4	46	12 (26)	0
Day 13 treatment					
DMBA	11	4	46	4 (9)	42†
12-OHM-7-MBA	5	5	63	7 (11)	0
7-OHMBA	4	4	55	3 (5)	0

* Resorption rate in control groups: mean 7 per cent.

† Note 100 per cent of surviving foetuses have malformations.

The effects of DMBA and 7-OHM-12-MBA in the pregnant Sprague–Dawley rat at day 8 or day 13 of pregnancy were similar in many respects, but clearly 7-OHM-12-MBA was the more potent embryopathic agent. Because DMBA and 7-OHM-12-MBA are embryopathic whereas 12-OHM-7-MBA and 7-OHMBA are not, it suggests that for embryopathic activity, as for adrenocorticolytic activity[5], derivatives of benz(a)anthracene must possess two active side chains situated at C-7 and C-12, with an intact methyl group at C-12 being mandatory, and at C-7 one of several possible substituents of which a hydroxymethyl group seems to confer the most potent activity.

With few exceptions the site and mode of action of embryopathic substances are largely unknown: they might have a direct toxic effect on differentiating tissues at the time of organogenesis, or affect the maternal environment or the placenta, or act by a combination of these factors. The mechanism of action of DMBA and 7-OHM-12-MBA in producing their embryopathic effects is as yet unknown.

DMBA and 7-OHM-12-MBA are potent adrenocorticolytic agents in the adult Sprague–Dawley rat, and all the pregnant rats treated with these compounds showed severe adrenocortical necrosis. There is a rapid fall in adrenal and plasma corticosterone levels beginning 24 h after treatment of rats with DMBA[6,7], and it is almost certain that 7-OHM-12-MBA has similar effects. It seems possible that such marked alterations in maternal adrenocorticosteroid levels, occurring at a critical stage of development, could affect the embryo. Adrenalectomy, however, in the pregnant rat does not cause teratogenic effects although there are conflicting reports as to whether it is associated with an increase in the resorption rate[8–12]. It is unlikely that the teratogenic effects reported here are directly caused by the maternal adrenal necrosis.

It has been reported that ovariectomized rats and mice deficient in progesterone produce congenitally abnormal foetuses[13,14], but in our experiments the ovaries of the DMBA- and 7-OHM-12-MBA-treated animals showed no histological abnormality.

Certain teratogenic factors are known to affect placental function[15,16]. In our experiments with 7-OHM-12-MBA and DMBA the placenta was reduced in size and showed histological changes, and it is possible that a disturbance in placental function may play some part in the production of the embryopathic effects.

A number of embryopathic substances are known to cross the placental barrier in rodents[17,18], and some of these may have direct toxic effects on developing embryonic tissues. Cytotoxic agents are thought to inhibit cellular proliferation in a non-specific fashion at critical stages of embryogenesis[19], but salicylates are believed to depress specifically the biosynthesis of mucopolysaccharides[20]. DMBA depresses the synthesis of DNA in certain rat tissues[21] and it is possible that 7-OHM-12-MBA may have similar effects.

It seems that the ultimate embryopathic substance may be a metabolite of 7-OHM-12-MBA because we have shown that the embryotoxic and teratogenic effects of 7-OHM-12-MBA at day 8 and day 13 of pregnancy respectively are inhibited by pretreatment with 2-methyl-1,2-bis-(3-pyridyl)-1-propanone (Metopirone, Ciba; Su 4885) or with β-diethylaminoethyldiphenyl-n-propyl acetate (SKF 525-A) (unpublished results). It is not known if the ultimate adrenocorticolytic and embryopathic agents are different derivatives of 7-OHM-12-MBA or where they are metabolized.

This investigation was supported by a grant to A. R. C. from the Scottish Hospital Endowments Research Trust. The DMBA was a gift from Dr Charles Huggins, Ben May Laboratory for Cancer Research, Chicago. We thank Mr G. Milne and Miss Barbara C. Cruden for technical assistance.

Early Pliocene Sediments and Fossils from the Northern Kenya Rift Valley

by
W. W. BISHOP
G. R. CHAPMAN
Department of Geology,
Bedford College,
University of London

Mammalian fossils, which include the tooth of an early hominid, have been recovered from the newly mapped Ngorora Formation in the Baringo District. Preliminary dating suggests that this formation is aged between 9 and 12 million years, and the new finds thus help to span a ten million year gap in the fossil mammal record in Africa south of the Sahara.

IN 1967, preliminary details were published of the discovery of mammalian fossils, including a hominid temporal, from the Kenya Rift Valley near Lake Baringo[1]. Geological investigation of the Baringo District has continued as part of a long term mapping project undertaken by the East African Geological Research Unit (EAGRU) based at Bedford College, University of London, and under the direction of Professor B. C. King.

In February 1968 in the course of the EAGRU mapping programme, one of us (G. R. C.) located a sedimentary formation from which some well preserved mammalian fossils, including the crown of a hominid molar, were recovered. The sediments outcrop in the Ngorora administrative location some twenty miles north-west of Lake Baringo (Fig. 1). Further, more detailed, stratigraphical and palaeontological investigations were undertaken during July and August of 1968 and 1969. The fossiliferous sediments are underlain and overlain by flows of phonolite lava for which preliminary potassium–argon dates have been obtained. These suggest that the sediments are aged between 9 and 12 m.y. Preliminary descriptions of the sediments and fossils follow, and the fossiliferous sequence is named the Ngorora Formation.

Ngorora Formation

This unit consists typically of well bedded, waterlaid fossiliferous sediments showing great variation in both thickness and lithology over the relatively limited extent of the outcrop. Lithologies are dominated by volcanic material, but range over a complete pyroclastic-epiclastic spectrum from primary pumice-tuffs and agglomerates to arenites and conglomerates composed chiefly of well rounded lava and feldspar clasts. Secondary zeolites are common in the coarser lithologies.

The Type Area

The maximum observed thickness occurs in the Ngorora location at Kabarsero, one and a half miles (2·4 km) north of Chepkesin, 0° 54′ N, 35° 51′ W (Fig. 1). A sedimentary sequence over 1,200 feet (360 m) in thickness conformably overlies a thick massive non-porphyritic phonolite flow. The whole succession dips at between 18° and

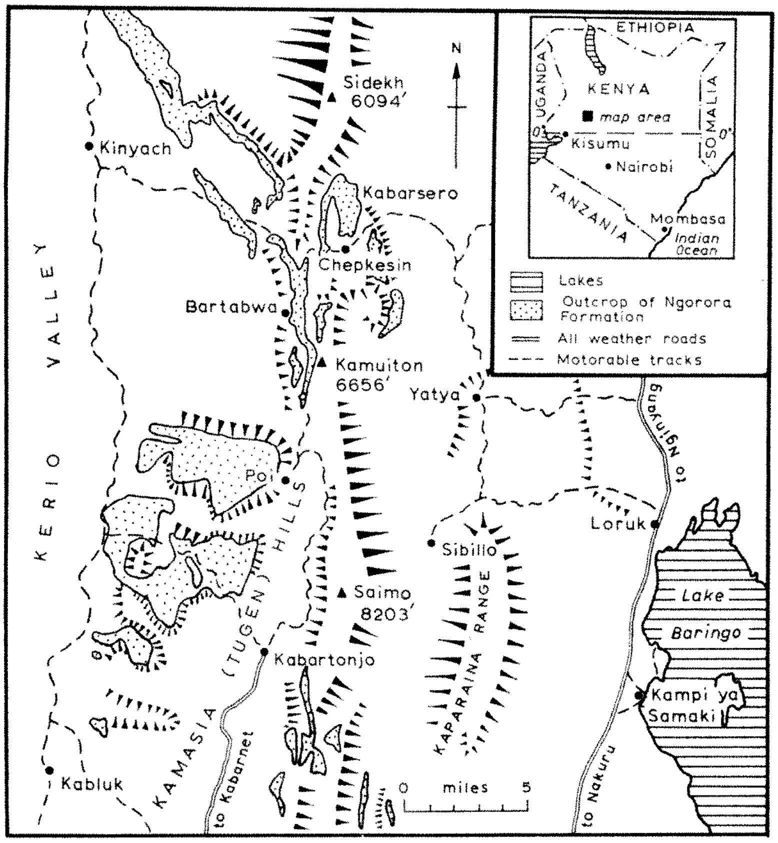

Fig. 1. Map showing the extent of the Ngorora Formation.

20° to the west. Five lithological subdivisions are recognized (*A* to *E*, Fig. 2).

E, diatomites, paper shales and coarse grit	350 feet +	105 m
D, rhythmic units with fossiliferous channel-conglomerates	220 feet +	66 m
C, porcellanous cream and green tuffaceous silts with pumiceous horizons	200 feet	60 m
B, rhythmic unit with fossiliferous channel-conglomerates and grits	140 feet	42 m
A, clays and coarse red tuffs	310 feet	92 m

A.—Variable bedded tuffs, tuffaceous clays and grit* lenses. The outstanding beds are massive tuffs with lava blocks which occur near the top and the base of the subdivision. These are stained red in patches but the red coloration is not as persistent in the type area as at other localities.

B.—Ferruginous pebbly grit and a prominent bed with tuff-boulders mark the base of this division. Above these beds, sedimentation is in the form of alternations of current-bedded grits, sands and clays with bedded pumice tuffs and tuffaceous silts. Because rhythmic sedimentation is typical of division *D* also, a standard bipartite unit is illustrated (Fig. 3) and described in more detail.

The lower part of this generalized unit shows a decrease upwards in the number of grit bands and in overall grain size. Vertebrate fossils are concentrated in the conglomerate and grit lenses and are often very abundant. Bones and teeth show a variable degree of rolling but are normally well preserved. (The principal fossil mammal horizons are indicated in Fig. 2, but fragments of fish occur in sandy beds throughout the sequence.) Well preserved chelonian remains occur more generally in the silts and clays of the middle of the unit. These are succeeded by glutinous clays containing kunkar and occasional rootlet casts. These clays are characteristic of palaeosols produced by the weathering of tuffaceous silts. Sedimentary dykes of silicified angular pumice tuff also occur marking infilling of open cracks on land surfaces. The dykes invariably terminate at one of the palaeosol horizons.

The upper part of the unit is composed of thin-bedded pumice tuffs, occasionally showing trough cross-bedding but typically very evenly bedded and fine-grained with a sharply defined base (see Fig. 3). These strata usually form cliffs. The fine grained sediments are frequently silicified to a brittle porcellanous rock with chert bands. Fragments of wood and fruits occur in the tuff above Loc. *2V/11*. The top of the bedded tuffs is often cut by channels containing the basal grit and conglomerate of the succeeding unit. This feature is well shown below Loc. *2V/1* where the fossil bearing deposits lie in channels which have cut through a massive accretionary lapilli-tuff producing pot-holes and water-worn blocks.

C.—This is essentially the upper part of the rhythmic unit of Loc. *2V/1*. It has been mapped separately to facilitate the study of thickness variations. It consists of cream and green well bedded tuffaceous silts exhibiting variable silicification and containing five coarser pumiceous horizons.

D.—Comprises three rhythmic units of which the lower two contain the fossil localities *2V/10* (the "Charnel House Grit"), *2V/11* and *2V/13*. The top of the sands and clays of Loc. *2V/11* is marked by a thin, 1·5 inch (40 mm), but laterally persistent pebble bed. This and the underlying sands were subjected to minor faulting and fissuring before the deposition of the overlying bedded tuffs.

E.—White diatomites and finely laminated diatomaceous and tuffaceous silts occur at the top of the sequence in the Chepkesin–Kabarsero area. Above this sequence is a prominent massive cross-bedded grit and conglomerate overlain by a thick tuffaceous silt; the grit and conglomerate make a prominent cliff above the road south of the old Chepkesin village.

Fig. 2. Lithological divisions of the Ngorora Formation in the type section at Kabarsero.

The sedimentary sequence is overlain by a massive phonolite, the youngest of the "plateau phonolite" group in the area.

Other Areas

Sections of the Ngorora Formation exposed on the crest and dip slope of the Sidekh hills, three miles to the west of Kabarsero, on the up-throw side of the Chepanda Fault (2,000 feet (600 m) throw) are only 100–150 feet (30–45 m) thick. Also a progressive thinning to 250 feet (75 m) is observed when the formation is traced south-south-westwards from Kabarsero toward the Saimo range (Fig. 1). There is everywhere a close correlation between the thickness of the formation and structural relief. Massive reddened tuffs characterize the basal horizons and a general increase of fine-grained well bedded lithologies occurs upwards.

When traced south and west from the type area, the Ngorora Formation is seen to have complex interdigitating relationships with the Poi Tuffaceous Sandstones and Kapkiamu Shales of Martyn[2], and lithologies identical to those of the Ngorora type-section comprise the southern outcrops of the Poi Tuffaceous Sandstones. It is more satisfactory to treat all these sediments, which mapping has shown to be a single lithosome, as one formation within which the details of the lateral variations remain to be resolved. It is therefore proposed that the Ngorora Formation should include the Poi and Kapkiamu units of Martyn.

Environmental Interpretation

Preliminary examination of cross-bedded structures, imbrications and channel orientations suggests sediment transport from between north and east. This seems to preclude derivation from the Kamasia itself, but thickness variations in the sediments show that the range was obviously a positive tectonic element within the basin of deposition.

Division *A* of the type section indicates early pyroclastic activity and several of the massive red tuffs with blocks may be lahar deposits. Units *B* and *D* are interpreted as the sedimentological results of movements on the rift faults bounding the depositional basin. The postulated sequence of events governing a rhythmic unit is: (i) Fault movement within the depositional basin producing tilting of the floor, with consequent channel erosion and deposition of coarse epiclastic sediments. (ii) Slight persistent movements tending to negate the previous tilting and resulting in progressively lower energy environments of swamps and alluvial plains with deposition of silts and clays. Fully subaerial conditions are represented by palaeosols and occasional primary tuffs which are seen locally to have been incised by stream channels. (i) and (ii) together produced the lower (sand/clay) part of the generalized unit (Fig. 3). (iii) Further faulting caused rapid transgression of lake waters across the alluvial plains and deposition of the pumiceous pyroclastics (probably originating within the Rift) in stillwater conditions. The wood and fruit in these sediments, and also the pumice fragments, would have been able to float to some distance from the shore. No mammalian fossils were found in this upper part of the unit.

Divisions *C* and *E* represent more stable periods of lacustrine deposition, the laminated diatomaceous tuffs of *E*, in particular, indicating an episode of tranquil lake conditions which was eventually terminated by the deposition of the conglomerate and grit at the top of the sequence.

Mammalian Fauna

The fossils collected from the Ngorora Formation include fish, reptiles, bird and mammals. Those identified to date are shown in Table 1.

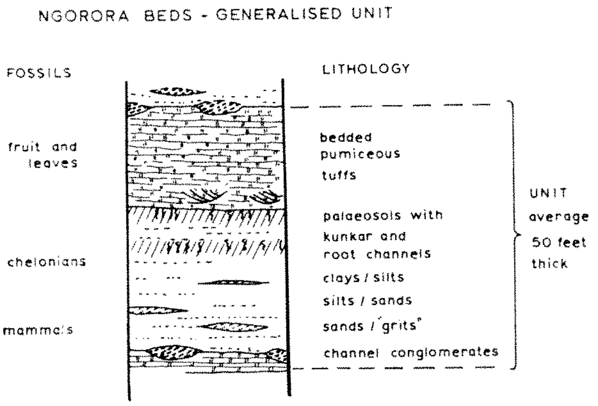

Fig. 3. Generalized unit typical of rhythmic sedimentation in divisions *B* and *D* of the Ngorora Formation.

Fossil plants also occur in the formation in the form of leaf and stem impressions, rootlet casts, fossil wood and occasional moulds of fruits.

The preliminary faunal list is based on specimens collected from more than twenty individual localities occurring within the 19 to 20 square miles of outcrop shown north of Kamuiton summit (6,656′) in Fig. 1. The majority of the localities fall, however, within an area of 2·5 square miles traversed by the type section at Kabarsero. Within the vertical sequence (Fig. 2), all but one of these fossil mammal localities occur in the channel grits and conglomerates of units *B* and *D*, and, as a result, the specimens are always in a dismembered, broken and sometimes rolled condition. The hominid tooth crown, in contrast, was from a manganese palaeosol horizon. The marabou stork skeleton was found partially articulated in a biotite bearing tuffaceous silt and seems to suggest rapid sedimentation in still water conditions well away from a channel.

Until larger collections are available and the existing specimens have been studied in detail it would be dangerous to attempt to establish an age for the mammalian fauna based on assessment of its stage of evolution, but some preliminary comments may be made on the nature of the fossils. We are indebted to Dr L. S. B. Leakey for the following note on the hominid tooth.

"The specimen consists of the crown of a left molar from which the roots have broken off (Fig. 4). The crown exhibits a well developed trigon with a rather large hypocone which is separated from the trigon by a relatively deep fissure. Both anterior and posterior contact facets are present. The former is rather larger than the latter, but its shape and size suggest contact with a molar rather than a premolar tooth, although this cannot be excluded. On the available evidence it may be assumed that the tooth is a second upper left molar. The crown is very low relative to the overall size, but this is not the result of wear on the cusps which show almost no attrition. On the lingual face a valley extends down to about half way point, while on the buccal face this valley is much less marked and ends in a very slight pit. There is a clear but small posterior fovea and a minute trace of an anterior one. Nowhere is there any trace of a cingulum. The tooth is fairly large, its measurements being length 12·35 mm; buccolingual width 14·00 mm. The posterior face is rather curved, while the anterior face is almost straight. Lingually, the enamel slopes slightly from the top of the cusps towards the neck of the tooth. A similar but not quite so marked feature is to be seen on the buccal aspect. At first sight this crown resembles the genus *Kenyapithecus*. Closer examination, however, shows characters which are suggestive of an evolutionary trend towards both *Homo* and *Australopithecus*. In fact, on morphological grounds, it would be possible to treat this specimen as a slightly aberrant tooth of either *Australopithecus africanus* or of *Homo habilis* except for the height of the crown which is distinctly lower relative to tooth size than is to be seen in teeth of either of these genera. It seems wisest at this stage to regard this specimen as representing a member of the Family Hominidae, having some affinities to *Kenyapithecus* (such as the very low crown) and some to both *Homo* and *Australopithecus*."

The other fossils will not be described in detail here. It should be noted, however, that rhinoceros material is abundant in most of the channel situations of unit *D*, and represents at least two and probably three genera. The absence of equid material from the collections made so far may prove significant as in the younger Baringo assemblages, aged seven million years or less, equids are represented in the form of *Stylohipparion*.

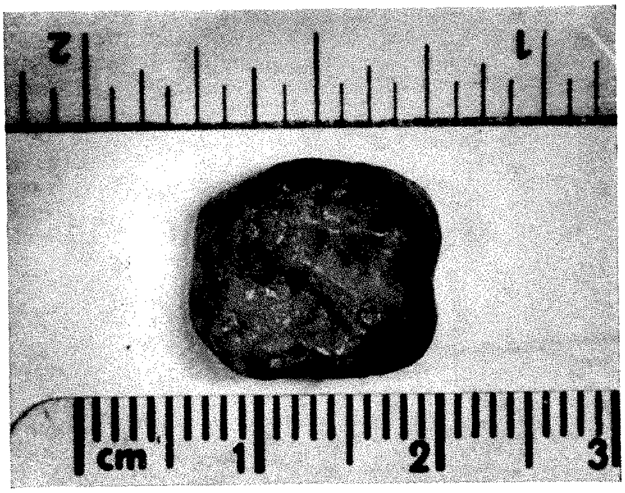

Fig. 4. Crown view of left upper molar of hominid from the Ngorora Formation.

The presence of horned bovids and of giraffoids in the artiodactyl assemblage suggests that at this time they were still in competition for similar niches in the environment. It is also worthy of note that these strata dated in excess of 9 m.y. contain teeth already having a recognizably hippopotamid morphology. These are at present the oldest dated "hippo" teeth, but the material is very sparse when considered as a percentage of the total assemblage in contrast to the dominance of hippo fossils in many Rift Valley localities of later date. This is probably of environmental rather than evolutionary significance.

Fish are represented by the individual bones and scales of dismembered skeletons at numerous horizons interspersed with and usually having an "overbank" relationship to the main Ngorora mammal bearing channels. As can be seen, however, from the faunal list, *Tilapia* has been identified from the Kapkiamu Shales. These fossils occur, frequently as complete skeletons, on the bedding planes of the shales. The individuals are small in size and limited in size distribution (80 to 100 mm long) which may be the result of adaptation in an alkaline lake basin of limited extent.

Chelonians are usually small and occur as fragments of skeleton and carapace which have broken up consequent upon mass movement in the tuffaceous clays. One large chelonian carapace (1·5 m long) was noted in a channel conglomerate of unit *D*.

We are indebted to the following who are undertaking detailed studies of the groups indicated: Dr A. Gentry (Bovidae and Giraffoidea), Dr J. Harris (Deinotheriidae), Mr A. Hill (Hyracoidea), Dr D. A. Hooijer (Rhinocerotidae), Dr L. S. B. Leakey (Primates), Mrs S. C. Coryndon Savage (Hippopotamidae), Mrs J. Van Couvering (Fish), Dr A. C. Walker (Ciconiidae) and Mr A. Wood (Chelonia).

Age and Palaeomagnetism

Potassium-argon ages are being established by Dr J. A. Miller in the Geochronological Laboratory, Department of Geodesy and Geophysics, University of Cambridge. Only preliminary dates are available at present (Fig. 2). It is not proposed to comment further on these ages beyond noting considerable variation in repeat runs and large probable errors, because of the presence of calcium carbonate and zeolites in the phonolite lavas. Further samples of the bracketing potash-rich phonolite lavas, together with sanidine feldspars from angular pumice fragments in units *B* and *D*, should allow accurate dates to be established for the fossiliferous horizons.

Although firm dates are still awaited from Ngorora itself, the formation and the overlying phonolite and basalt lavas are unconformably overlain by flows of Kabarnet Trachyte. Potassium-argon dates for these trachytes are in good agreement with each other and have small probable errors. They suggest an isotopic age of 7·0± m.y. as a firm upper age limit for the Ngorora Formation plus superincumbent lavas. When mapping evidence of unconformity is taken into account, an age in excess of 9·0± m.y. seems confirmed for the fossiliferous sediments. The age of 12·0± m.y. or younger for the underlying phonolite also receives support by extrapolation from the ages obtained for the plateau phonolites of the Uasin Gishu escarpment[3].

A model 70 portable fluxgate magnetometer was used to establish polarities for lava flows overlying and underlying the Ngorora Formation. The field results show good agreement in the polarities obtained for up to six readings on each flow unit, but these are being checked against "cleaned" laboratory readings. The lavas overlying the Ngorora Formation, including the Kabarnet Trachytes, yield normal polarities in the field although to the north of Kamuiton Hill (Fig. 1) a thin reversed flow may occur between the normal flows and the sediments. The underlying phonolites yield reversed field polarities.

Significance of the Ngorora Formation

The Ngorora Formation is interpreted as the product of intermittent fluvio-lacustrine deposition, involving both the eroded debris of earlier volcanism and the redistribution of coeval pyroclastic material on an intermittently subsiding rift floor.

The fossils fall in the early Pliocene (or possibly late Miocene) time span for which nothing is known of mammalian evolution in Africa south of the Sahara. The fauna helps to bridge the gap between the Fort Ternan assemblage (14·0± m.y.), which also includes horned bovids and giraffoids, and the earliest mammalian assemblages with australopithecines from the Omo and East Rudolf areas of the northern Gregory Rift (2·0± to 4·0 m.y.). The search for further hominid material from this time span is of critical importance.

We thank Dr L. S. B. Leakey and Professor E. Aguirre for kindly undertaking palaeontological work in the Ngorora area in July 1969. Chief Harun Loyetta provided valuable local assistance and Andrew Hill, Paul Buckland and Edward Spooner helped with the field work. The field work was supported by grants from the Kenya Government, the Natural Environment Research Council, the Wenner-Gren Foundation for Anthropological Research and the Boise Fund of Oxford University.

Received March 17, 1970.

Geology and Fauna of a New Pliocene Locality in North-western Kenya

by
BRYAN PATTERSON

Department of Geology and Geophysics, Yale University

Lothagam Hill reveals a succession of fossil bearing sediments that extend knowledge of the East African Pliocene back from the base of the Omo succession, to about 5·5 million years

In 1967, an expedition from the Museum of Comparative Zoology, Harvard University, worked a new Pliocene locality at Lothagam Hill in south-eastern Turkana District, Kenya. Fossils had been noticed there by Dr Lawrence H. Robbins in the course of archaeological excavations carried out in 1965. A preliminary geological map of the locality was made by W. D. S. and B. P. in 1967, and more detailed work was carried out by A. K. B. in 1968. Studies of the faunas are in progress and a detailed report by A. K. B. on the geology is in preparation.

Lothagam Hill is an isolated, westward-tilted fault block situated in the plain adjacent to Lake Rudolf between the Kerio and Lomunyenkupurat Rivers (Fig. 1).

It is situated at approximately 2° 53′ N latitude and 36° 04′ E longitude, covers about 10 square miles and has a maximum relief of 200 m above the plain, which in turn is about 370 m above sea level. The block is composed of Miocene and Pliocene volcanics and sediments with major normal faults running north–south along the eastern edge. The topography is controlled by two relatively resistant volcanic units. These form roughly parallel north–south ridges, with sediments between and to the west (Fig. 2). Overlying these older rocks unconformably are horizontal, subrecent deposits from a former high stage of Lake Rudolf. A preliminary account of the archaeology of these late deposits has been given by Robbins[1], who assigns them to Fuchs's 220 foot level, and they have been dated by carbon-14 at about 5,000 yr BP (personal communication from L. H. Robbins).

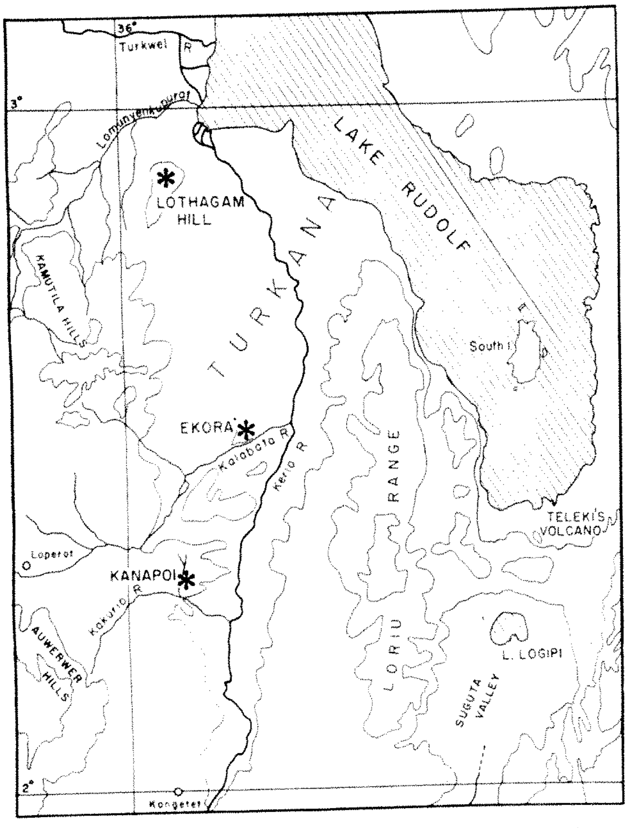

Fig. 1. Map showing position of the Lothagam, Kanapoi and Ekora localities.

Stratigraphy

A generalized stratigraphic column is given in Fig. 3. The total thickness of the Lothagam section exceeds 950 m, and the sediments make up about 720 m of this. The lowest exposures consist of two series of lava flows with some interbedded water-laid deposits. These series are separated by a major disconformity and may be referred to as the Miocene and Pliocene volcanics on the basis of whole rock K–Ar determinations: 16·8 ± 0·5 m.y. on a Miocene flow (Geochron R-0906), and 8·31 ± 0·25 m.y. on a Pliocene flow (Berkeley JA-2294). Conglomerates and water-laid tuffs become increasingly common toward the top of the Pliocene volcanic series, and the boundary between this and the overlying fossiliferous sediments is set at a disconformity on the uppermost basalt flow. The only fossils encountered were pieces of silicified wood in the Miocene volcanics and a few shells of *Etheria elliptica* in the Pliocene.

The overlying sedimentary deposits form three distinct lithological units. A basalt sill some 30 m thick (the first to be recorded for the East African late Caenozoic) has been intruded between the first and second of these, and postdates the sediments. The sill has yielded a whole rock K–Ar date of 3·71 ± 0·23 m.y. (Berkeley KA-2262), thus placing an upper limit on the age of the sedimentary sequence as a whole; it shows reversed polarity (personal communication from P. K. S. Raja), and may have been intruded early in the closing third of the Gilbert Reversed Epoch[2]. The sedimentary sequence and the basaltic sill may be designated as the Lothagam Group, and the three sedimentary units, from bottom to top, as Lothagam-1, 2 and 3.

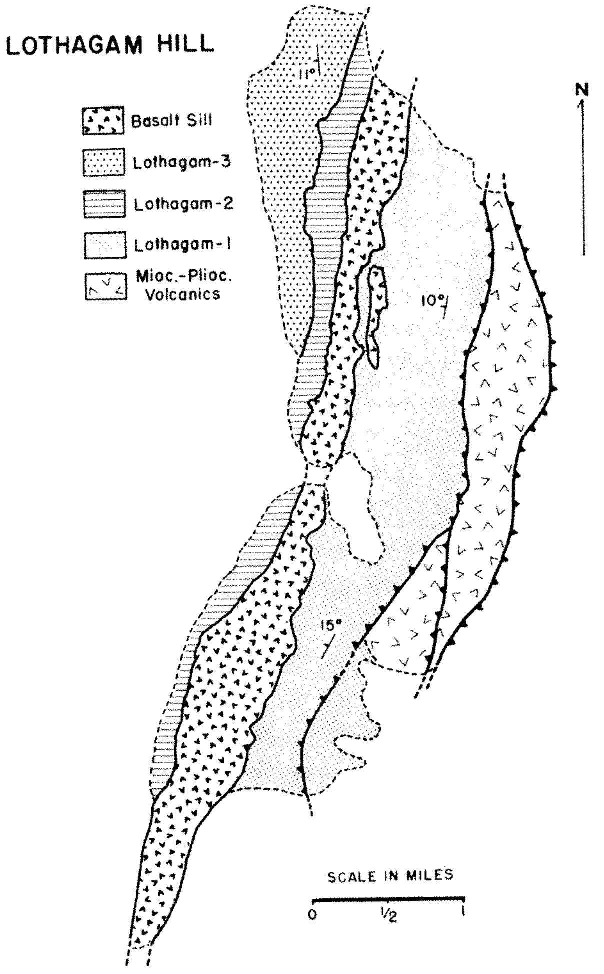

Fig. 2. Simplified geological map of Lothagam Hill; subrecent sediments are not shown and minor faults have been omitted.

Lothagam-1. This unit, the lower fossiliferous beds of Maglio[3], has produced the richest and best preserved fauna. It is 480 m thick in the north and 370 m thick in the south, and has the general characteristics of a clastic wedge deposited on the edge of a rapidly subsiding basin. This could well have been the ancestral Lake Rudolf Basin, opening out to the north. There is no geological or faunal evidence for any major time breaks within the formation; deposition was apparently continuous, although at varying rates. The deposits are clearly fluvio-deltaic in origin, and indicate the presence of at least one major river system as a transporting and depositing agent. Sediment types range from coarse, poorly sorted conglomerates and sandstones to fine silts and laminated tuffaceous shales. The sedimentary structures and bedding associations indicate deposition in channel, floodplain and backwater environments. Water flow throughout the year rather than seasonally is suggested by the molluscan fauna (especially banks of large *Etheria elliptica*) and the absence of evaporite deposits. Lithological differences permit three subdivisions of Lothagam-1, which have been designated in the section as Members *A*, *B* and *C*, from bottom to top. The lowest, *A*, consists of coarse, non-fossiliferous conglomerates and sandstones, the middle of alternating sandstones and silts, and the upper of well sorted channel sandstones with some silt lenses. Member *B* contains the richest fossil fauna in the northern part of the exposures, while Member *C* is most prolific in the south. The uppermost beds of *C* are baked as a result of the intrusion of the sill.

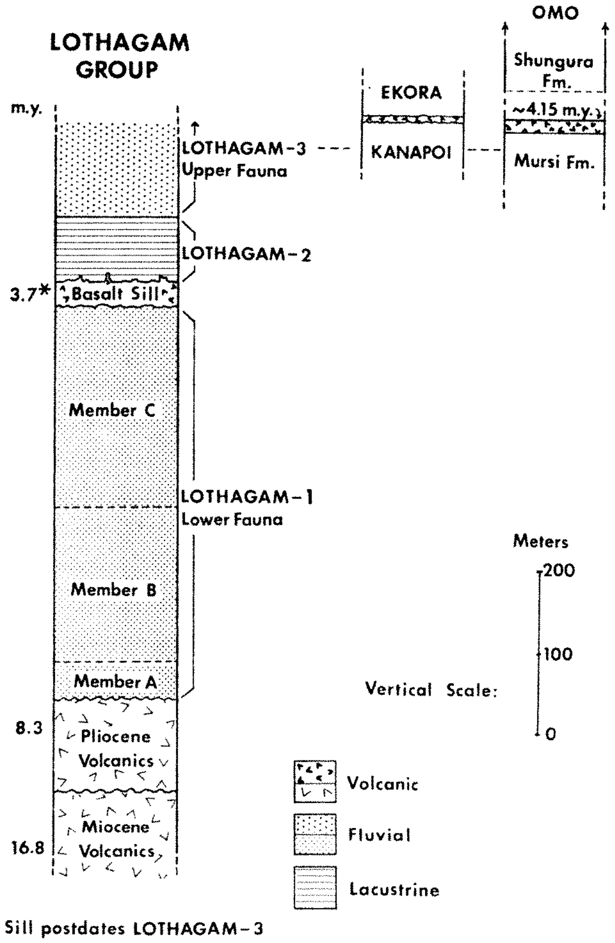

Fig. 3. Columnar section of the Lothagam succession and its relations to Kanapoi, Ekora and the base of the fossiliferous Omo succession. For broader correlations, see Maglio[3].

Lothagam-2. This unit is an 80 m thick sequence of fine grained silts, clays, and occasional water-laid tuffs indicating a change to a lacustrine environment of deposition. Fossil vertebrates (hippopotamus, crocodile, turtle, fish) are rare, but beds of gastropods up to a metre thick are fairly common; identified gastropods are: *Bellamya unicolor*, *Caelatura* ? sp. B and *Cleopatra bulimoides*. Gypsum and salt in the deposits are evidence for at least partly saline conditions. The lower beds of the unit are contorted and baked, again as a result of the intrusion of the sill.

Lothagam-3. This unit, the upper fossiliferous beds of Maglio[3], lies conformably on Lothagam-2 and demonstrates a return to a fluvial environment of deposition. The top is not exposed because it is concealed beneath subrecent to recent alluvium, but the unit exceeds 90 m in thickness. The sediments are similar to Member *C* of Lothagam-1, consisting of coarse sandstones and floodplain-type silts and clays. Vertebrate fossils occur, although because of low relief and deeply weathered exposures they are much fewer in number than those found in Lothagam-1. There are no apparent faunal or stratigraphic breaks within the unit.

Fauna

The fauna of Lothagam-1, so far as identified, is as follows: Cercopithecidae indet., *Australopithecus* sp. cf. *A. africanus*, Anomaluridae nov., Hyaenidae indet., cf. *Civettictis*, Felinae indet. (a large form), Machairodontinae indet., Orycteropodidae gen. et sp. nov., *Deinotherium* sp., Gomphotheriidae indet., *Stegotetrabeledon orbus*[4], *Primelephas gomphotheroides*[4], *Stylohipparion* sp., *Brachypotherium* sp. nov., *Nyanzachoerus* spp. nov. B and C, *N.* sp. cf. *N.* sp. nov. A, *N.* sp., *Hippopotamus* (*Hexaprotodon*) spp. nov. A and B, *Giraffa* sp., *Tragelaphus* sp. cf. *T. nakuae*, *Gazella* sp., *Redunca* sp. aff. *R. ancystrocera*, other Bovidae, *Crocodylus* sp., *Euthecodon* sp., Squamata indet., Pythoninae indet., *Podocnemis* spp. nov. A and B, *Geochelone* sp., Trionychidae indet., fish, *Bellamya* ? sp., *Ampullaria wernei*, *Lanistes carinatus*, *Caelatura* ? sp. A, *Melanoides* sp., *Etheria elliptica*. The mammalian assemblage is clearly earlier than that from Kanapoi. Only one species, *Nyanzachoerus* sp. nov. B, is at present definitely known to be common to the two (personal communication from H. B. S. Cooke and R. F. Ewer). The elephants of Lothagam-1 are more primitive than those characteristic of Kanapoi; granting that *Primelephas* is ancestral to later forms[3,4], an estimate of 1·0 to 1·5 m.y. for the time interval between deposition of the two formations is not unreasonable. Lothagam-1 provides a very useful standard against which to assess the relative ages of other faunas. It seems to be slightly older than Kolinga and lower Kaiso, equivalent, at least in part, to Kaperyon (which seems to be related to trachytes radioactively dated around 5 m.y.; personal communication from W. W. Bishop) and somewhat younger than Sahabi[3]. 5·0 to 5·5 m.y. would seem to be a plausible estimate for the age of Lothagam-1.

The few fossils found in Lothagam-2 are useless for purposes of correlation; the differences between the molluscs of this formation and of Lothagam-1 are the result of environmental factors—lacustrine vs. fluvio-deltaic depositional environments.

The scanty fauna of Lothagam-3 consists of *Simopithecus* sp., *Loxodonta adaurora*[4], *Stylohipparion* sp., Hippopotamidae indet. (a fragment), *Nyanzachoerus* sp. nov. B, *Notochoerus* sp. cf. *N. euilus*, *Tragelaphus* sp., other Bovidae, *Crocodylus* sp., *Euthecodon* sp., *Podocnemis* sp. nov. A, Trionychidae indet., fish, *Etheria elliptica*. Apart from *Simopithecus* (represented by a single tooth), all these forms occur in the Kanapoi and correlation with that fauna seems reasonably certain.

Age of the Kanapoi Fauna

The age of the fauna from the Kanapoi Formation now requires re-examination. When first reported, all that could be said of it was that it was pre-Olduvai and might be of early Pleistocene, "Villafranchian", age[5]. This estimate seemed to be nearly in accord, within the limits of the error, with a whole rock K–Ar date of 2·9 ± 0·3 m.y. (Geochron R-0554) for the overlying basalt, which exhibits reversed polarity. A subsequent date of 2·5 ± 0·2 m.y. (Geochron R-0554) seemed to accord perfectly with the palaeomagnetic evidence[6]. Recently, a third date of 2·71 ± 0·26 m.y. (Berkeley KA-2261) has been obtained. Since publication of the first two dates the recognized number of magnetic reversals has increased considerably[2], and it is now uncertain, in view of the spread of the dates, as to whether the Kanapoi basalt falls early in the Matuyama Reversed Epoch or in either the Kaena or the

Mammoth Events of the Gauss Normal Epoch. Recent findings have, however, made it clear that none of the dates accords with the evidence of the fauna. A revised, but far from final, faunal list of the Kanapoi is as follows: *Parapapio jonesi*[7], cf. *Australopithecus*[6], *Lepus* sp., *Hystrix* sp., *Tatera* sp., *Enhydriodon* sp. nov., *Hyaena* sp., Machairodontinae indet., *Deinotherium bozasi*, *Anancus* sp., *Stegotetrabeledon* sp. ? (fragments)[3], *Loxodonta adaurora*, *Elephas ekorensis*[4], *Stylohipparion* sp., *Ceratotherium* sp. nov., *Nyanzachoerus* spp. nov. A and B, *Notochoerus* sp. cf. *N. capensis*, *N.* sp. cf. *N. euilus*, *Hippopotamus* (*Hexaprotodon*) sp. nov. C, *Okapia* sp., *Giraffa* sp., *Tragelaphus* sp., *Reduncini* ? sp., other Bovidae, *Crocodylus* sp., *Euthecodon* sp., *Podocnemis* sp. nov. A, *Geochelone* sp., Trionychidae indet., fish, molluscs. If the ages obtained for the basalt accurately reflected the age of the sediments beneath it, this fauna should correlate approximately with that associated with Tuff *D* (ref. 8) in the Shungura Formation[9] of the Omo sequence. It does not, being notably more primitive. Like Lothagam-1, Kanapoi now provides a standard of comparison for other faunas. It may be correlated, in whole or in part, with Kanam, Chemeron, early Laetolil and Mursi (Yellow Sands)[3,4,10]. The last of these is capped by a basalt radioactively dated at 4·05 ± 0·2 m.y.[8] and 4·25 m.y.[9]; this dating falls into sequence with 3·75 ± 0·2 m.y. obtained for Tuff *B* (ref. 8) near the base of the Shungura Formation, and 3·95 ± 0·11 m.y.[11] for the unfossiliferous Nkalabong Formation[9]. An age between 4·0 and 4·5 m.y. for the Kanapoi Formation is a reasonable estimate on available evidence. The discrepancy between the radioactive dates for the Kanapoi basalt and the date indicated for the fauna is a question to be settled by future work. The basalt may be a sill. Where exposed its upper surface is weathered, but it is possible that detailed investigation around the Ekora anticline might decide the matter. If a sill, it is a rather extensive one.

The Ekora Sediments

The 1967 expedition recognized a yet higher sedimentary unit that overlies the Kanapoi basalt. Reconnaissance in 1966 had traced the Kanapoi sediments and lava northward to Ekora, just south of the junction of the Kerio and Kalabata Rivers, where they are involved in a low, east–west trending anticline; patches of sediment overlying the basalt were seen on the north limb of the anticline[6].* This structure plunges westward at a low angle and the basalt dips under immediately west of the Kalabata River. The area to the west of this point is largely covered by superficial deposits and a scanty vegetation cover, but patches of underlying sediments are here and there exposed. Fortunately, in the immediate vicinity of the basalt, a moderately resistant bed of orange-brown grit occurs; this could be traced around the nose of the basalt and observed to be concordant with it in dip and structure, thus showing that the sediments participate in the anticline, overlie the basalt and are hence younger than Kanapoi. No continuous section of them is available, the exposures are poor and the top is not visible. They appear to be predominantly fine-grained with some beds of sandstone and grit; the finer sediments contain fragmentary remains of fish and other aquatic vertebrates and a few terrestrial forms have been recovered from the coarser sediments. The fauna consists of *Anancus* sp., *Loxodonta adaurora*, *Elephas ekorensis*, *Ceratotherium* sp. nov., *Nyanzachoerus* sp. cf. *N.* sp. nov. B, *Euthecodon* sp., *Podocnemis* sp. nov. A, *Geochelone* sp., fish and molluscs.† This assemblage is consistent with the stratigraphic data and represents a continuation from the Kanapoi fauna. (This demonstrates that the Kanapoi basalt was not extruded some 2·7 m.y. ago over an old surface of Kanapoi sediments.) The elephants suggest that the Ekora may be older than the Shungura. *Elephas ekorensis* is ancestral to *E. recki*, and an early stage of that species is present in the lower part of the Shungura at Tuff *B* (ref. 3). Even with a generous extension of Pleistocene time—to the base of Etouaires in the European Villafranchian succession at 3·3 m.y.[12]—Lothagam, Kanapoi and Ekora are clearly of Pliocene age.

A final point concerning this sequence of faunas is that the fishes and molluscs occurring in them have, like those in the Omo sequence[9], chiefly nilotic affinity. This indicates a drainage system then open to the north. These formations have been affected by diastrophic movements that, among other things, resulted in the general westward dip of the rocks in the region. These tectonic events, which gave the Lake Rudolf basin its present configuration, evidently ended in Pleistocene, possibly mid-Pleistocene, time.

The East African Pliocene

In the past five years there has been a remarkable increase in knowledge of the continental late Caenozoic in East Africa. Well established chronology previously ended at the base of the Olduvai sequence. Isolated localities—Kanam, Kaiso, Laetolil, Kanapoi (when first discovered)—were recognized as or suspected of being pre-Olduvan in age, but there was no standard against which they could be compared. The recent understanding of the Omo succession[8,9], which overlaps Olduvai in time and extends back beyond 4 m.y., has helped enormously in this connexion. Ekora, Kanapoi and Lothagam, which in turn overlap Omo, carry the chronology back to around 5·5 m.y. or more. Recent work in the Baringo basin has made known fossil bearing sediments that correlate at the top with Kanapoi and Mursi and reach back, although separated by gaps, to beyond 9·0 m.y.[13]. The East African Pliocene, hitherto unknown or essentially unrecognized, is now a reality.

The field work was supported by the US National Science Foundation; a grant from the Milton Fund of Harvard University has helped to defray the costs of radioactive dating. We thank our companions in the field, A. D. Lewis, R. C. Wood, V. J. Maglio, J. H. Wahlert, C. T. Williams, A. E. Greer, D. M. Ngumi, S. Rueben and M. Nathale; the Ministry of Natural Resources, Kenya; Dr and Mrs L. S. B. Leakey and the staff of the National Museum Centre for Prehistory and Palaeontology; Dr J. Walsh and the staff of the Mines and Geological Department, Kenya; Dr and Mrs R. J. Drysdale-Anderson and the staff of the African Inland Mission, Lokori; and Mr Richard Leakey of the National Museum of Kenya. For comment, information and determinations we thank W. W. Bishop, H. B. S. Cooke and R. F. Ewer, S. Coryndon Savage, A. W. Gentry, D. A. Hooijer, F. C. Howell, B. Kurtén and E. Anderson, V. J. Maglio, P. K. S. Raja, K. S. Thomson, B. Verdcourt, J. Walsh and R. C. Wood. The potassium–argon dating was carried out by H. W. Krueger and N. J. Gilbert.

---

* Sediments encountered to the south of Kachau Cone were then regarded as an extension of the Kanapoi. This now seems very doubtful. These isolated, horizontally lying, predominantly coarse deposits do not resemble anything found elsewhere in the area, and the few fossils collected from them—fragments of hippopotamus, giraffe and bovid—are unrevealing as to precise age. They are probably Pleistocene.

† *Simopithecus* sp.[4] was mistakenly listed previously; the specimen in question was found in Lothagam-3.

Bradford's Law and Library Acquisitions

by

WILLIAM GOFFMAN

School of Library Science,
Case Western Reserve University,
Cleveland, Ohio

THOMAS G. MORRIS

Cleveland Medical Library Association,
Cleveland, Ohio

Bradford's law holds for periodical circulation as well as literature dispersion.

In a recent article[1], B. C. Brookes pointed out that Bradford's law of dispersion "seems to offer the only means discernible at present of reducing the present quantitative untidiness of scientific documentation, information systems and library services to a more orderly state of affairs capable of being rationally and economically planned and organized". This opinion is shared by others who have applied the Bradford and related distributions to various problems of library management; see, for instance, the survey by M. K. Buckland and A. Hindle[2]. Much of this untidiness is related to the lack of methods for determining the minimum size or lower limits of a useful collection of information sources. In this communication, we report on a method using Bradford's law to establish such lower limits for the purpose of maintaining a dynamic library collection. The upper limits, being essentially a function of budget, reach their own level by natural processes. We shall limit our discussion to the acquisition of periodicals in a medical library, although the method should be equally applicable to most scientific libraries.

Bradford's law of dispersion[3] states that, if the journals containing articles on a given subject are arranged in descending order of the number of articles they carried on the subject, then successive zones of periodicals containing the same number of articles on the subject form the simple geometric series $1 : n^2 : n^3 : \ldots$ Bradford called the first such zone the nucleus of periodicals particularly devoted to the given subject. Clearly, the nucleus is arbitrarily defined because it depends on the number of articles chosen to effect the division of periodicals into zones. Hence, Bradford's law, although an interesting phenomenon, was of little practical use. It was shown, however, that there is a minimal nucleus in the sense of Bradford[4,5]. That is, a core of journals can be separated from the top of an ordered list of periodicals dealing with a given subject which represents the most significant information sources for that field. This minimal nucleus, moreover, does not necessarily consist of only the most productive periodical, but may contain any number of journals depending on the extent of dispersion of the subject's literature among the various periodicals. Thus it is possible to set lower bounds on the number of journals which must be contained in a collection devoted to a given subject.

Nucleus of Journals

Brookes has also pointed out[1] that Bradford's law "can be expected to arise when selection is made of items, characterized by some common element, which are all equally open to selection for an equal period and subject to the 'success-breeds-success' mechanism". Hence, Bradford's law should apply to the use of periodicals in a library as well as to the dispersion of articles among journals. These are both acquisitions processes; namely, processes of obtaining relevant items by means of selection.

Table 1 shows the distribution of journal use in the Allen Memorial Medical Library, Cleveland, Ohio, during its peak month of March 1968. Use is here defined as circulation. Clearly, Bradford's law holds for this distribution. Table 2 shows the minimal nucleus and its successive zones of periodicals. These have been derived from consideration of the data about the least used titles, as was described in an earlier paper[4]. In general, the number of items effecting the finest Bradford subdivision must exceed one half the number of items of frequency one in the distribution. In this case, nine partitions would yield zones of periodicals each of which circulated about ninety-seven times, a number approximately equal to one half the number of periodicals which circulated once. Hence, eight zones constituted the finest subdivision of these data for which the Bradford hypothesis was valid. The minimal nucleus of journals circulated during March 1968 consisted of eleven titles that were borrowed 113 times, followed by sixteen periodicals circulating 108 times, twenty-one journals 107 times and so on. Consequently, successive zones of periodicals circulating about the same number of times formed the approximate geometric series $1 : (1{\cdot}4) : (1{\cdot}4)^2 : \ldots . : (1{\cdot}4)^7$. It is interesting to note that half the circulation for this month was accounted for by only seventy-six journals.

Table 1. JOURNAL CIRCULATION FOR MARCH 1968

No. of journals	Circulation per journal	No. of journals	Circulation per journal
1	18	12	6
1	12	15	5
2	11	28	4
1	10	36	3
3	9	75	2
7	8	186	1
4	7		

Table 2. MINIMAL NUCLEUS OF JOURNALS CIRCULATING IN MARCH 1968

Zone	Times circulated	No. of journals	Bradford constant (n)

6	110	55	1·4
7	109	93	1·7
8	109	109	1·2
	876	371	Average 1·4

Acquisitions Policy

Assuming that journal circulation in this library obeys Bradford's law, as seems to be the case, the following acquisitions policy can be formulated. In establishing such a policy it is important to base the selection of journals on expected future demand. Hence:

(1) First establish the minimal nucleus and its successive zones of periodicals circulating at various successive time intervals. The length of these intervals will vary from

library to library with the density of use. Some libraries may compute the nucleus each month, others every three months and so forth. This is necessary because the nucleus may vary with time as a result of a change in users or user interests.

(2) On the basis of these observations, establish the rate of change of circulation for each periodical circulating in the library.

(3) On the basis of these rates of change, establish by any appropriate means of extrapolation the expected circulation at some appropriate future date, say a year in advance.

(4) The expected minimal nucleus should then belong to the minimal collection in the library's inventory at that point in time.

As a safety factor it may be good policy for the library not to delete a given journal from its collection until its predicted decline in circulation is verified by fact.

Nucleus of Users

If the budget allows, it may be in the library's interest to include those periodicals which are of greatest interest to its best customers, provided they do not already appear in the minimal nucleus of circulating journals. Table 3 shows the distribution of users of journals in the Allen Library for the peak month of March 1968, and Table 4 shows the minimal nucleus and its successive zones of users during this time period. Use is again defined as circulation. The user distribution for March 1968 obeys Bradford's law whence the minimal nucleus of users consisted of thirteen individuals who borrowed journals 118 times, followed by eighteen individuals using periodicals 108 times, twenty-four individuals with 107 and so on. Thus successive zones of users borrowing about the same number of journals formed the geometric series $1:(1{\cdot}4):(1{\cdot}4)^2:\ldots:(1{\cdot}4)^7$. We note that half of the circulation was accounted for by only eighty-six users. We can thus

(1) Establish the minimal nucleus of users of the library.

(2) Determine the areas of interest of the members of this nucleus, in terms of *Index Medicus* subject headings. For medical researchers this can be done by selecting the headings from *Index Medicus* under which their most recent publications have been indexed. For clinicians, residents and interns this may be done by interest profiles.

(3) Establish the minimal nucleus for each subject heading represented by the user nucleus. This is done by applying Bradford's law to the distribution of articles among journals under each of the subject headings.

(4) The totality of such minimal nuclei should then be added to the minimal nucleus of circulating journals to form the library's minimal collection.

Table 3. DISTRIBUTION OF USERS FOR MARCH 1968

No. of users	Circulation per user	No. of users	Circulation per user
2	12	18	5
2	10	29	4
2	9	44	3
9	8	68	2
3	7	211	1
6	6

8	109	109	1·1
	876	394	Average 1·4

Transplantation-Immunology Literature

That the distribution of articles among journals as indexed in the *Index Medicus* satisfies Bradford's law is shown in Tables 5 and 6, which give the distribution of articles and minimal nucleus of journals for the subject heading "Transplantation-Immunology" in *Index Medicus* for the years 1965–1968.

Table 5. DISTRIBUTION OF ARTICLES UNDER HEADING TRANSPLANTATION-IMMUNOLOGY

Journals	Articles per journal	Journals	Articles per journal
1	124	1	13
1	71	2	12
1	66	1	10
1	54	6	9
1	40	4	8
1	28	6	7
1	25	1	6
1	24	9	5
1	22	19	4
1	19	20	3
1	17	34	2
3	15	155	1

Table 6. MINIMAL NUCLEUS FOR TRANSPLANTATION-IMMUNOLOGY 1965–1968

Zone	Articles	Journals	Bradford constant (*n*)
1	124	1	—
2	137	2	2·0
3	122	3	1·5
4	122	6	2·0
5	122	11	1·8
6	129	20	1·8
7	126	35	1·8
8	118	74	2·1
9	120	120	1·8
	1,120	272	Average 1·8

The minimal nucleus for transplantation-immunology, not surprisingly, consisted of the single periodical *Transplantation*, the second zone contained the journals *Nature* and *Surgical Forum*, the third *Annals of the New York Academy*, *Proceedings of the Society for Experimental Biology and Medicine*, *Journal of Immunology* and so on.

Because it has been shown that Bradford's law applies to a portion of a literature as well as its totality[4], any part of the transplantation-immunology literature could have been chosen for this experiment. In practice, it would be best to take the most recent publications in establishing the minimal nucleus for a given field.

The expected minimal nucleus of users as well as the expected minimal nuclei of the subject areas of their interest at some appropriate future date can be established by extrapolation, and in this way the library can be in a position to anticipate future demand. In this case it may be a good policy to include new titles in the collection on the basis of these predictions.

In summary, it has been shown that the distributions of both circulating periodicals and their users in a medical library seem to obey Bradford's law. Hence, a smallest core of journals which must belong to the library's collection can be defined. This core should consist of the minimal nucleus of periodicals circulating in the library plus the minimal nuclei of journals devoted to the subjects of most interest to the library's nucleus of users. As the budget allows, successive zones of periodicals corresponding to circulation and user interest can be added. As a result, the library collection can be maintained in an orderly and viable state, thus providing its patrons with the most potentially usable materials for the funds at its disposal.

LETTERS TO THE EDITOR

PHYSICAL SCIENCES

Diamonds and the Interstellar Extinction Curve

IT has been suggested[1] that the interstellar extinction might be explained by assuming that the interstellar dust is composed of an appropriate size distribution of diamond particles. The imaginary part of the index of refraction of diamond increases sharply from near zero to about 1·0 at $\lambda^{-1} = 5{\cdot}0\ \mu\text{m}^{-1}$, giving an albedo near unity in the visible and strong extinction in the ultraviolet, as required by recent observations.

Wickramasinghe[2] has recently published a theoretical extinction curve for diamond particles, using a distribution of particle radii

$$n(a) \propto a^{-3} \qquad (1)$$

The curve passes within the error bars of the observations of interstellar extinction from $\lambda^{-1} = 1{\cdot}0$ to $8{\cdot}0\ \mu\text{m}^{-1}$ but gives too little extinction in the infrared and also results in a ratio of total to selective extinction, $R \equiv A_V/E_{B-V}$, of 10·8. Wickramasinghe therefore concludes that the hypothesis of dust grains made of diamonds is in conflict with the observations. The purpose of my paper is to show that a simple size distribution of diamonds may be found which accounts for the interstellar extinction.

I have made a series of exact Mie calculations with various simple size distributions and have found that the distribution

$$n(a) \propto a^{-3{\cdot}8} \qquad (2)$$

fits the observations throughout the infrared, visible and near ultraviolet regions fairly well. The ratio R for this distribution is 4·3, in agreement with the accepted range of values between 3 and 6. The number of very small particles is very large in such a distribution, however. Kimura[3] has shown that small dust grains may be expected to be destroyed by cosmic rays of energy 10–100 MeV if the grains are not able to thermalize the energy of the collision. I have therefore modified the size distribution to have the form

$$n(a) \propto a^{-3{\cdot}8}(1 - e^{-a/a_c}) \qquad (3)$$

A value of $a_c = 0{\cdot}03\ \mu\text{m}$ reduces n to 50 per cent of its value in distribution (2) at $a = 0{\cdot}02\ \mu\text{m}$ and to 10 per cent at $a = 0{\cdot}003\ \mu\text{m}$, and gives the best fit with the observations (see Fig. 1). For this distribution $R = 4{\cdot}9$.

The calculations were made by numerically integrating the extinction cross-section over the size distribution between particle radii 0·001 and 10 μm. The size of the increment in radius was made smaller at those wavelengths and radii where the cross-section shows rapid variations with the parameter $x = 2\pi a/\lambda$. The smallest increment used was 0·001 μm. The optical constants used were those of Phillipp and Taft[4].

In Fig. 1 is plotted the extinction in magnitudes, normalized to $V = 0$, $B - V = 1$, of the distribution (3) of diamond particles with $a_c = 0{\cdot}03\ \mu\text{m}$. Also plotted are the observations, similarly normalized, reported by Boggess and Borgman[5], those of Stecher[6] in the ultraviolet on five pairs of stars, those of Stecher[7] on one pair of stars, and those of Bless and Savage (private communication) made from the Orbiting Astrophysical Observatory on ten pairs of stars. The curve is nowhere more than one and a half error bars away from the observed points.

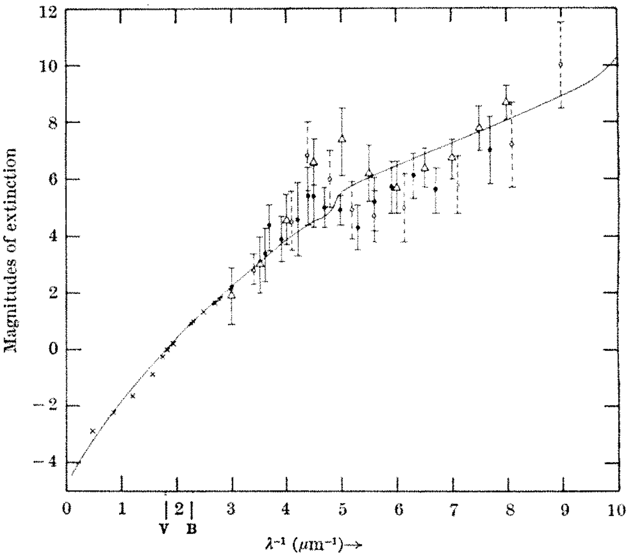

Fig. 1. Normalized extinction curve for a size distribution of diamond particles defined by $n(a) \propto a^{-3{\cdot}8}(1 - e^{-a/0{\cdot}03})$. The observations of Boggess and Borgman[5] are shown as crosses; those of Stecher[6] as filled circles; those of Stecher[7] as triangles; and those of Bless and Savage (private communication) as open circles. The normalization is according to $\Delta m = 0$ at $\lambda^{-1} = 1{\cdot}8\ \mu\text{m}^{-1}$, $\Delta m = 1$ at $\lambda^{-1} = 2{\cdot}3\ \mu\text{m}^{-1}$.

It is concluded that a simple size distribution of diamond particles can be found which gives a calculated extinction curve satisfying the observational data as satisfactorily as any other model of interstellar grains so far proposed. It should be noted, however, that the existence of such a distribution does not constitute a strict test for the composition of the dust grains. A simple distribution which fits the extinction observations could probably be found for particles composed of many different materials.

I thank Dr William Irvine of the University of Massachusetts for the use of his Mie computation program and J. E. Gaustad and W. C. Saslaw of the Department of Astronomy, University of California at Berkeley, for helpful discussions.

Mascons, Mare Rock and Isostasy

THE nature of the large positive gravity anomalies discovered on the Moon[1] (mascons) has been the subject of lively discussion. The high density (3·1 to 3·5 g cm^{-3}) of mare rocks at Tranquillity Base[2] supports one hypothesis—that mascons are surface sheets of high density volcanic rock[3]. The non-isostatic conditions of the mascon areas shown by the free-air anomalies[4,5] may have terrestrial analogues in some regions of recent volcanism where breaks in the crust have allowed dense basalts to pile up on the surface faster than isostatic balance can be maintained.

The form and magnitude of the mascon anomalies can be accounted for by sheets of mare volcanic rock denser than the rock of the adjacent highlands[3,5]. Should highland rock, which probably includes anorthosite of density 2·8–2·9 g cm^{-3} (ref. 6), prove to average less dense than mare rock by as much as 1 g cm^{-3}, then the large Mare Serenitatis and Mare Imbrium anomalies may represent mare sheets 10–15 km thick[3,5]. A third of this thickness would be unsupported isostatically, in inverse proportion to the excess density over highland rock. This imbalance would correspond to loads of the order of 200 bars.

If mare rock causes the anomalies, the question of why some maria have no anomalies may be answered in terms of the ages of the basins which they fill. The well identified mascons are all associated with relatively fresh and easily recognizable mare-filled circular basins: Imbrium, Serenitatis, Crisium, Nectaris and Humorum[1]. On the other hand, some of the mare areas without mascons, namely Tranquillitatis, Nubium and Fecunditatis, are in what appear to be degraded circular impact basins older than any of the mascon basins[7]. Thus only mare rock in the younger large impact basins seems to be isostatically unbalanced.

The maria themselves are younger than any of the large circular basins and were formed during a period of extensive volcanic flooding[7]. If all mare rocks are 2–4 × 10^9 yr old as reported for the Apollo 11 and 12 samples[8,9], then the non-isostatic condition has persisted for a long time during which the rigidity has been sufficient to support regional loads of the order of 200 bars.

I propose that before mare flooding the lunar rigidity was much less than after, so that considerable isostatic adjustment was possible before but not after. This sequence is suggested by a contrast in morphology between young and old craters. With rare exceptions most post-mare craters are deep although they are as much as 2–4 × 10^9 yr old, yet many pre-mare craters have shallow raised floors that indicate isostatic uplift[10]. Some of the large impact basins are old enough so that, by the time flooding started, substantial isostatic levelling would have already occurred. As a result, only a thin layer of mare material was deposited in these old basins. Younger basins had not yet reached equilibrium and were still deep by the time flooding started, so they were filled with a great thickness of mare material, in excess of the amount that would be isostatically balanced. By this time, the outer part of the Moon had cooled to a more rigid state so that isostatic adjustment could not take place.

Similar volcanic flooding on Earth apparently can also cause temporary imbalances, which rectify themselves through isostatic creep during prolonged periods of quiescence. Positive gravity anomalies characterize the young basalt provinces of Hawaii[11] and Snake River Plain[12], and some large regions of young oceanic flood basalts, notably the Iceland–North Atlantic area and the Kerguelen–Crozet area[11]. One interpretation of these regions is that relief of pressure by breaks in the crust, such as by sea-floor spreading, leads to inward lateral transfer of material in the asthenosphere. The resulting excess material piles up above its equilibrium level rather than spreading out because the crust in these areas is too cool to creep rapidly[11]. Why the excess crust does not sink into a flowing asthenosphere has not been explained; it seems clear, nevertheless, that the dynamics of volcanism keep these regions unbalanced. They contrast with areas where volcanism ended before the Tertiary and approximate isostatic equilibrium was restored by slow creep, and with areas such as the south-east Pacific, where heat flow is high and isostasy maintained despite current volcanism[11].

This brings us to a possible explanation for the apparent isostatic equilibrium of Oceanus Procellarum. This vast mare area may represent not merely volcanic flooding into a crustal scar, as in the case of the circular basins, but a major centre of high heat flow. It has already been suggested that three major volcanic plateaus in Oceanus Procellarum may hint at an origin similar to that of the terrestrial mid-ocean ridges[13]. Thus, by analogy with the south-east Pacific, the Procellarum region may have been warm enough to maintain isostasy during loading.

Reliable gravimetric data over most of the Moon are indispensable for assessing the various mascon explanations that have been proposed. It will be particularly exciting to discover whether gravity anomalies are associated with circular basins not flooded with mare, such as several on the far side or the basin near Schiller, or with very ancient flooded circular basins such as that occupied by Mare Australe[7]. The hypothesis proposed here predicts that such basins have no mascons.

Apollo 11 Evidence for the Differentiation of Lunar Materials

THE first detailed chemical analysis of lunar rocks[1] has renewed interest in the problem of the origin of the Moon. Although many controversies revolve around this question, it is reasonable to begin with the hypothesis that the Moon was originally formed from a cloud of gas and dust approximating the solar or "cosmic" composition and that it underwent the obvious differentiation not only with respect to certain gases but also with respect to more refractory elements. Differentiation could have occurred within the hypothetical solar nebula itself even before separation of the condensed body, through ambipolar diffusion in a mixture of neutral and ionized gases in a magnetic field[2] or by differential magnetic forces on solids[3]. It could also have occurred during condensation and agglomeration into the condensed sphere and later through igneous and metamorphic processes. Discussions of possible differentiation through magmatic processes have already been given by Salisbury[4], O'Keefe and Cameron[5], Lowman[6] and Walter[7].

The chemical compositions of the rocks must also be considered in relation to the history of the entire surface. In general the data so far tend to substantiate Baldwin's thesis[8] that the surface features, including the circular maria, owe their existence chiefly to impact explosions of solid bodies varying in kinetic energy. An important corollary which follows from this thesis is that the lunar deposits have been strewn and restrewn across the surface and that they have been disturbed to depths of the order of many kilometres. The extent to which igneous and other processes have modified this picture of lateral and vertical mixing is as yet unknown but is subject to test by chemical analyses such as these discussed here.

A parameter which has been found useful in correlating certain geochemical data is the first ionization potential of an element[9]. Indeed, this parameter also enters directly into the theory of ambipolar diffusion and so should be directly related to possible differentiation in the preplanetary nebular gas[10]. Figs. 1 to 3 show plots against the ionization potentials of elemental abundances of a representative lunar sample[1], of the Earth's crust[11] and of the class I carbonaceous chondrites[12]. In each case the plots are normalized to the elemental abundances of the solar gas[12], and the abundance of silicon is assumed to be the same in all cases.

Perhaps the most significant feature of the chemical analyses is the great similarity of composition of all the rocks from Tranquillity Base. The uniform abundances of Ti, Fe, Mg, Ca and Na are especially marked. Another significant feature is the qualitative similarity between the distribution patterns of the lunar rocks and of the Earth's crust (Fig. 2). It is interesting that the parallel holds despite the high crustal abundances of elements with low ionization potentials.

The abundances of certain of the chief constituents such as Ti, Fe and Na differ greatly from their abundances in basalts, which are the most similar common terrestrial rocks in other respects[13]. Particularly anomalous in terms of terrestrial rocks is the combination of high values of the atomic fraction Fe/(Fe + Mg) and low Na. In terrestrial igneous differentiates Fe/(Fe + Mg) and the albite content usually increase together and this holds even when absolute iron enrichment occurs (my unpublished work).

The lack of resemblance between the lunar elementary abundance distributions and that of the class I carbonaceous chondrites (Fig. 3) is to be expected because the latter are usually regarded as the least differentiated condensed matter known from the solar system[14]. Comparison with the lunar patterns thus immediately indicates that the lunar materials have undergone some differentiation among the refractory elements.

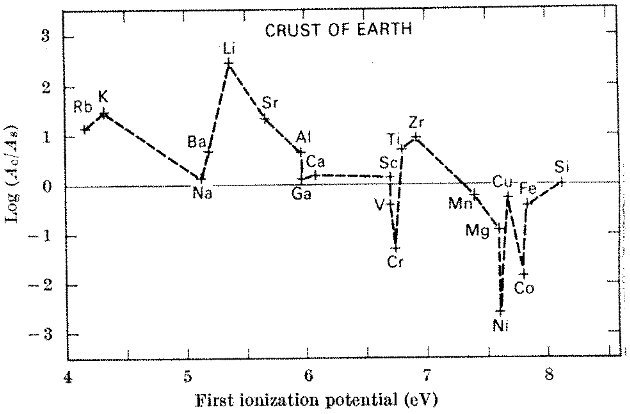

Fig. 2. Normalized logarithms of the elemental abundances in the Earth's crust[11] plotted against the first ionization potentials. A_c indicates the crustal elemental abundances and A_s indicates the solar elemental abundances to which the A_c values are normalized.

The rocks from Tranquillity Base have such high densities that even the vesicular rocks can be up to 3·4 g cm^{-3}. It seems likely that the true densities are even higher than this. The fact that these densities exceed the mean density of the Moon (3·34 g cm^{-3}) points to a differentiation process by which iron is preferentially concentrated in the outer layers. Indeed, the gravitational instability which such a situation implies has its parallel on Earth in the differentiated and layered gabbroic bodies such as the Skaergaard[15] complex of east Greenland and the Stillwater[16] complex of Montana. In the case of the Stillwater complex[16] the fractionation of Fe^{2+} and Mg between the earliest melt, as represented by rocks of a quenched border facies and the olivine crystals precipitated initially, is such that iron is highly concentrated in the melt relative to Mg. Similar relations also apply to the Skaergaard complex[16], so that in the terrestrial differentiated complexes analogous to the lunar rocks, iron is highly concentrated in the melt relative to magnesium as crystallization proceeds. The Apollo 11 data also point to a similar relation for the rocks at Tranquillity Base if the fractionation is estimated from the olivine phenocrysts and the rock as a whole.

It has been shown experimentally[17] that crystallization in the system MgO–FeO–Fe$_2$O$_3$–SiO$_2$ under anhydrous and reducing conditions leads both to an increase of the Fe^{2+}/Mg^{2+} ratio in the melt and to absolute iron enrichment. Operation of the same mechanism in the gabbroic complexes leads to a compositional layering in which the density increases upward in the stratigraphic sequence[15]. Thus the high densities of the lunar surface rocks are not surprising because a partial melting of the lunar layers by any of a number of mechanisms could result in a melt enriched in iron relative to the unmelted residue. Such a melt might well have a density lower than the surrounding solid rock due to considerable expansion on melting[18], so that it would move to the surface under buoyant forces.

An important difference between the terrestrial and lunar rocks is the low water content of the latter indicated by the lack of hydrous phases. Water has the effect of increasing the solubilities of the feldspars relative to those of the ferromagnesian minerals in the melt so that under high water pressures, such as are attainable on Earth, the melt and the crystallization products tend to be feldspathic[13]. On Earth this process seems to give rise to large volumes of rock belonging to the granite–diorite series which form the bulk of the continental crust and which are reflected in Fig. 2. As previously noted, the lunar rocks seem to be more like the relatively anhydrous

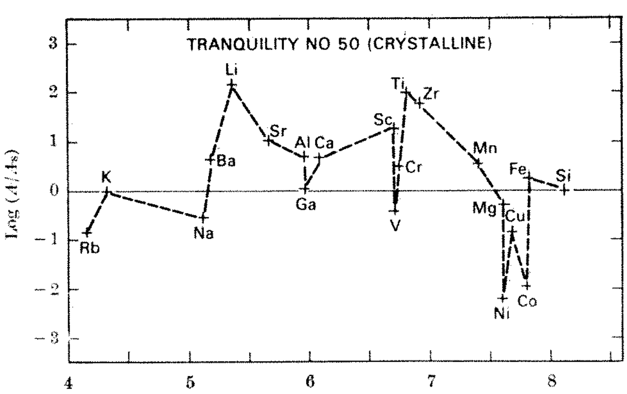

Fig. 1. Normalized logarithms of the elemental abundances of a representative lunar rock type[1] from Tranquillity Base plotted against the first ionization potentials. A indicates the lunar elemental abundances, and A_s indicates the elemental abundances to which the A values are normalized. The size of the crosses corresponds to 10 per cent uncertainty in the chemical analyses.

terrestrial gabbros because they contain large amounts of ferromagnesian minerals. Walter[7] has already called attention to an analogous effect of low water pressure on the melting properties of the lunar rocks.

The high TiO_2 contents of the specimens from Tranquillity Base can be accounted for in part by magmatic differentiation of the gabbroic type, as this oxide has been observed to increase upward in the Skaergaard complex[15]. It is possible that concentration of TiO_2 in the melt is even more favoured under conditions of low oxygen fugacity which would inhibit its precipitation as titaniferous magnetite. It is also possible that a relatively small initial difference between the magmatic source rocks of Tranquillity Base and those of terrestrial basalts could be amplified by differentiation.

In summary, the compositions of the surface rock at Tranquillity Base seem to be consistent with a differentiation mechanism, perhaps of a complex character embodying igneous and other processes, but which probably contained elements similar to that which produced the crust of the Earth. There are important modifications induced by the low water content of the lunar rocks, however.

I thank Dr L. S. Walter for interesting discussions.

Surface Temperature of the Early Earth and the Nature of the Terrestrial Atmosphere

THE detailed models of solar evolution now available clearly indicate that the luminosity of the Sun has been gradually increasing since it first arrived on the main sequence some 5×10^9 yr ago. If it is assumed that any changes in the orbit of the Earth during this time have been periodic—so that the present orbit is very nearly the average orbit—then it follows that the value of the solar constant has also increased correspondingly. The possibility of a resultant variation in the surface temperatures of the planets is of particular interest for the Earth, which is the only planet at present possessing a considerable quantity of water in the liquid state on its surface.
